**Abstract**

**Background:** *Rhipicephalus microplus*, an invasive tick species of Asian origin and the main vector of *Babesia* species, is considered one of the most widespread ectoparasites of livestock. The tick has spread from its native habitats on translocated livestock to large parts of the tropical world, where it has replaced some of the local populations of *Rhipicephalus decoloratus* ticks. Although the tick was reported in Uganda 70 years ago, it has not been found in any subsequent surveys. This study was carried out to update the national tick species distribution on livestock in Uganda as a basis for tick and tick-borne disease control, with particular reference to *R. microplus*.

**Methods:** The study was carried out in Kadungulu, Serere district, south-eastern Uganda, which is dominated by small scale livestock producers. All the ticks collected from 240 cattle from six villages were identified microscopically. Five *R. microplus* specimens were further processed for phylogenetic analysis and species confirmation.

**Results:** The predominant tick species found on cattle was *Rhipicephalus appendiculatus* (86.9%; *n* = 16,509). Other species found were *Amblyomma variegatum* (7.2%; *n* = 1,377), *Rhipicephalus evertsi* (2.3%; *n* = 434) and *R. microplus* (3.6%; *n* = 687). Phylogenetic analysis of the 12S rRNA, 16S rRNA and ITS2 gene sequences of *R. microplus* confirmed the morphological identification.

**Conclusions:** It is concluded that *R. microplus* has replaced *R. decoloratus* in the sampled villages in Kadungulu subcounty, since the latter was not any longer found in this area. There is currently no livestock movement policy in force in Uganda, which could possibly limit the further spread of *R. microplus* ticks. Future surveys, but also retrospective surveys of museum specimens, will reveal the extent of distribution of *R. microplus* in Uganda and also for how long this tick has been present on livestock without being noticed.

**Keywords:** *Rhipicephalus microplus*, Ticks, Serere district, Uganda, Tick-borne diseases

Full list of author information is available at the end of the article
regions in Africa, *R. microplus* has successfully competed and replaced the close related African blue tick, *Rhipicephalus decoloratus* [2–4]. *Rhipicephalus microplus* is vector of *Babesia bovis* and *Babesia bigemina* causing extensive production losses [5–7].

*Rhipicephalus microplus* has been introduced from Asia on cattle exported to East and South Africa via Madagascar [3]. Similarly, *R. microplus* was introduced into Ivory Coast and Benin from Brazil 10 years ago [8]. Since then, it has spread to Burkina Faso, Mali, Togo and very recently into Nigeria and Cameroon [3, 8–12]. This species is now well established in the southern and eastern fringes of South Africa [2, 7]. Displacement of local *R. decoloratus* populations in the countries where *R. microplus* was introduced could have resulted from the faster life-cycle of *R. microplus*, sterile off-spring of interspecific mating [2] or because of the higher degree of acaricide resistance of *R. microplus* [2].

There are a few isolated reports of *R. microplus* in East Africa, notably Tanzania and South Sudan [13, 14]. Some of these reports are over 30 years old [15, 16]; hence, this tick species could have spread to several parts of East Africa. Given that *R. microplus* is an invasive tick species, such isolated reports are likely to be due to a lack of regional or country-wide tick surveys and the distribution may be wider than reported. Furthermore, the differential diagnosis of *R. microplus* and *R. decoloratus* in East Africa and *R. decoloratus*, *Rhipicephalus annulatus* and *Rhipicephalus geigyi* in West Africa is difficult because of similarities in morphology and their small size [4].

There are no up-to-date Ugandan or East African tick surveys. As a result, despite records of *R. microplus* 70 years ago in the Uganda [17], this has never been confirmed. This study was carried out in one of the high tick density districts of south-eastern Uganda to update national tick species data as a basis for a national tick and tick-borne disease control strategy.

**Methods**

**Study area**

The study was carried out in Serere district, south-eastern Uganda, in 2017. The district is made up of two rural counties (Kasilo and Serere), eight sub-counties (Bugondo, Kadungulu, Pingire, Labor, Atiira, Kateta, Chere and Serere/Olio) encompassing 254 cattle-owning villages. Tick collections were conducted in Kadungulu sub-county. Serere district was selected because it has a large number of small scale livestock producers (1–50 cattle per herd) whose potential to commercialise livestock production is primarily constrained by ticks and tick-borne diseases. Six of the 254 villages were randomly selected for this study (Fig. 1).

**Cattle herd and individual animal selection**

Farmers in Serere district predominantly keep short-horn East-African Zebu cattle in communal village herds. Given that any animal sampled from each of these villages is likely to be infested with ticks, the number of villages (*n* = 6) and animals selected (*n* = 240) need not to be based on any rigorous statistical...
methods. However, to estimate the chance of finding *R. decoloratus* ticks, we conducted a power calculation assuming a prevalence of 5% at *P = 0.01*; we expected to find 18 *R. decoloratus* ticks in a sample size of 18,000 ticks [18]. In this study we sampled 19,007 ticks. Cattle were included in this study if they had not been sprayed against ticks for the past two weeks, were young (1–2 years old) and non-fractious. Young non-fractious animals were preferred for inclusion because they were easier to restrain and poses very low risk of injury to themselves or personnel. An average of 40 cattle was sampled from each of the six selected villages. All cattle sampling sites were geo-referenced prior to tick collection.

**Tick collection and identification**

Selected cattle were physically restrained before half-body tick collections were carried out. Each of the collected ticks was morphologically identified to the genus level before they were preserved in 70% ethanol. The tick samples were then transferred to Makerere University for further species identification using taxonomic keys [19]. Five representative *R. microplus* specimens were selected for molecular species confirmation based on 12S ribosomal RNA (12S rRNA), 16S ribosomal RNA (16S rRNA) and the internal transcribed spacer 2 (ITS2) gene sequences [4, 20]. A taxonomically and molecularly confirmed *R. microplus* specimen was photographed under a stereomicroscope (Olympus model SZX7, Tokyo, Japan).

**DNA extraction**

Prior to tick DNA extraction, each tick was cleaned in five one-minute steps, each step involving centrifugation at 10,000× rpm in freshly prepared 1.5 ml of phosphate-buffered saline (PBS). Individual clean ticks were immersed under liquid nitrogen for 5 min and thereafter crushed with a sterile mortar and pestle to create a tick homogenate. DNA was then extracted from each tick homogenate using DNeasy Blood and Tissue Kit (Qiagen, Germantown, MD, USA) following the manufacturers’ instructions. The presence and quality of DNA were checked by resolving 5 µl of the extracted DNA on a 1% agarose gel and viewing them under an ultraviolet transilluminator. The remaining DNA was stored at −20 °C until use in the downward amplification steps.

**DNA amplification**

PCR amplification was performed on 12S rRNA and 16S rRNA genes and the ITS2 spacer using primers (Table 1) and thermocycling conditions as previously described [4, 19]. Each reaction was prepared into a final volume of 50 µl containing: 1× reaction buffer (670 mM Tris-HCl, pH 8.8, 166 µM (NH₄)₂SO₄, 4.5 % Triton X-100, 2 mg/ml gelatin) (Bioline, Humber Road, London, UK), 0.25 mM of each dNTP, 0.25 mM each of forward and reverse primers, 1.56 U *BioTaq* DNA polymerase (Bioline, London, UK), 1.25 mM MgCl₂, 32.2 µl of PCR grade water and finally 5 µl of the template DNA.

The 16S ribosomal RNA gene was amplified in a thermocycler (Personal Thermocycler, Biometra, Göttingen, Germany) with initial denaturation of 94 °C for 5 min followed by 30 cycles at 94 °C for 30 s, 48 °C for 45 s, 72 °C for 45 s and a final extension at 72 °C for 7 min. Amplification of the ITS2 and 12S ribosomal RNA was performed using similar thermocycling conditions to those of 16S at annealing temperature of 55 °C and 52 °C, respectively. PCR products were resolved on 2% agarose gels. The resultant PCR products were sized against a 1 kb DNA molecular ladder (Bioline, London, UK). The expected PCR product sizes ranged between 300–1200 bp. PCR products were purified using QIAquick PCR Purification Kit (Qiagen, Germantown, MD, USA) and commercially Sanger-sequenced (Inqaba Biotec, Mucklenuek, Pretoria, South Africa).

**Gene sequence analysis**

Each of the 12S rRNA, 16S rRNA and ITS2 tick sequences from this study were queried in a BLASTn search with default settings (NCBI BLASTn software version 2.6.10) [21] to reveal their identity. The query sequence identity was assigned/matched based on the hits (tick species sequences returned) with the highest identity scores (≥ 80%) and most significant E-values (closest to 0.0). The identified query sequences from this study were annotated and submitted to the GenBank database under the accession numbers MK332390, MK332391, KY688455, KY688459, KY688461 and KY688467.

Annotated sequences from this study were each analysed in a multiple sequence alignment (MSA) with their corresponding reference gene sequences downloaded

**Table 1** List of primer sets used in PCR amplification of 12S rRNA and 16S rRNA genes and the ITS2 region [4, 20]

| Primer name | Primer sequence (5’-3’) |
|-------------|------------------------|
| 16S-F | TAAATGCTGTGTTGATT |
| 16S-R1 | CCGGTCTGAACCTASAWC |
| ITS2-F | ACAATTGGGACCTGGTGCTT |
| ITS2-R | TCCTGGATCTGAAGGTCGAC |
| T1B | AAACATGGATTAGATACCC |
| T2A | AATGAGAGCGAGCGGGGATGT |
from GenBank using the ClustalW algorithm in MEGA version 10 [22]. The MSA files were used to infer nucleotide similarity between sequences from this study and their corresponding nucleotide reference sequences from GenBank. Each of the data sequence sets were analysed in MSA using the ClustalW algorithm and trimmed in MEGA software version 10 [23, 24]. Phylogenetic analysis for each nucleotide sequence set was performed using the maximum likelihood method utilising the Tamura 3-parameter with Gamma distribution with 1000 bootstrap replicates [23] as the best-fit model to infer phylogenetic relatedness among the gene sets.

To evaluate the 12S rRNA, 16S rRNA and ITS2 sequence divergence of newly typed Ugandan R. microplus ticks and their corresponding reference sequences from GenBank, pairwise genetic distances were calculated in MEGA software version 10 [23] using default settings for each sequence.

**Results**

**Tick collections**

Adult ticks (n = 19,007) were collected upon completion of half-body counts from 240 cattle. The majority (86.9%; n = 16,509) of these ticks were Rhipicephalus appendiculatus. Other tick species identified were Amblyomma variegatum (7.2%; n = 1377), R. microplus (3.6%; n = 687) and Rhipicephalus evertsi (2.3%; n = 434). The mean adult tick density was 79 ticks per animal. On average, the numbers of adult R. appendiculatus, A. variegatum, R. microplus and R. evertsi per animal were 138, 11, 6 and 4, respectively.

A taxonomically and molecularly confirmed R. microplus specimen was photographed under a stereomicroscope as shown in Fig. 2. Female R. microplus was characterized by hypostome teeth in a typical 4 + 4 column arrangement and internal margin palpal article 1 lacking protuberance and distinctly concave. Male R. microplus carried typical indistinct spurs on the ventral plates.

**Molecular confirmation of R. microplus**

Five of the 687 ticks that were identified as R. microplus using standard taxonomic keys were further analysed and all confirmed R. microplus by assessing sequence variation of their 12S rRNA, 16S rRNA and ITS2 regions. The genetic diversity of R. microplus ticks recovered from Uganda and those from elsewhere ranged between 0–0.075 (Table 2). Phylogenetic analysis of the 12S rRNA (Fig. 3), 16S rRNA (Fig. 4) and ITS2 (Fig. 5) regions

* Present study

![Fig. 2](image-url) **Morphological identification of R. microplus.** a Female, ventral view (1, hypostomal teeth in a typical 4 + 4 column arrangement; 2, short palp of internal margin article 1 lacking protuberance and is distinctly concave; 3, cornua). b Male, ventral view (4, distinctly small adenal plates; 5, ventral plate spurs (small accessory adanal plates); 6, caudal appendage; 7, genital aperture with a broad U-shape)
revealed polymorphic sub-grouping with *R. microplus* collected from other parts of the world. The Ugandan *R. microplus* isolates were notably similar to those collected in Taiwan, Mozambique, Nigeria, the USA and South Africa.

**Discussion**

The high burden of adult ticks on cattle in Kadungulu sub-county, Serere District, south-eastern Uganda, confirms that ticks and associated diseases (anaplasmosis, babesiosis, theileriosis and heartwater) constitute a major constraint to livestock production in this region [25, 26]. It has been reported previously that *R. appendiculatus*, vector of *Theileria parva*, is the predominant tick species in Serere District [26–29]. Besides the discovery of *R. microplus* and the complete absence of *R. decoloratus*, the other tick species were the same as reported before in south-eastern Uganda [25–28]. However, the Ugandan tick population structure varies greatly between the different regions of the country, due to variation in micro-climatic conditions [25–27]. For example, *Amblyomma lepidum*, *Hyalomma truncatum*, *Amblyomma gemma* and *Rhipicephalus pulchellus* thrive under the arid conditions of north-eastern Uganda [27, 30], and were therefore not found in this less arid study area.

In “The ixodid ticks of Uganda” Matthysse & Colbo [16] reported a systematic survey of ticks on livestock conducted between 1965–1966, wherein not a single *R.
A microplus tick was found. Interestingly, before this survey, *R. microplus* was reported from Uganda by S. G. Wilson, who conducted a limited survey on cattle along the borders of Karamoja district, closer to the border with Kenya [17]. It is unlikely that *R. microplus* may have been missed during the nation-wide survey conducted by Matthysse & Colbo [16], now more than 50 years ago, although the sample size of 491 cattle was limited. Interestingly, our results clearly indicate that *R. microplus* has been overlooked for years, since it takes years to replace an indigenous population of *R. decoloratus* ticks [31]. Given the invasive nature of this tick species, exacerbated by poor animal movement control and communal grazing practices within the East African region, it may be the case that populations of *R. microplus* are now well established in Uganda.

Unprecedented levels of acaricide-resistant tick populations have recently been reported in Uganda [33]. The molecular phylogenetic analysis may be a useful tool to discern possible relationships between isolates collected from different geographical regions. In this study, the 12S rRNA and ITS2 regions of the tick isolates from Uganda were identical to those previously isolated from Taiwan, Mozambique, Nigeria, USA and South Africa. It is therefore plausible that the *R. microplus* ticks collected from cattle in south-eastern Uganda were introduced on livestock imported from the southern parts of Africa. In the past 10–15 years, there have been significant importations of dairy cattle into Uganda from South Africa to improve the Ugandan dairy herd through cross-breeding [32]. However, a more extensive genotyping of ticks collected from different geographical areas is required to confirm this [26, 33].

Fig. 4 Phylogenetic analysis based on the tick 16S ribosomal RNA gene. A phylogenetic tree based on 16S rDNA sequences. The tree was generated by the maximum likelihood method based on the Tamura 3-parameter model. The analysis involved 25 nucleotide sequences. Orange circles represent samples sequenced in this study.
Fig. 5  Phylogenetic analysis based on the ITS2 spacer of the ribosomal RNA gene cluster of ticks. A phylogenetic tree based on ITS2 rDNA sequences. The tree was generated by the maximum likelihood method based on the Tamura 3-parameter model. The analysis involved 32 nucleotide sequences. Orange circles represent samples sequenced in this study.
cause of this problem is due to farmer-related factors (acaricide overuse and misuse) potentiated by lack of national acaricide and animal movement control policies [33–35]. Under such favourable conditions, *R. microplus* tick populations are known to rapidly become acaricide-resistant as a result of target specific mutations and metabolic adaptations [36]. The introduction of *R. microplus* into Uganda is likely to exacerbate the already existing problem of ticks and tick-borne diseases in three ways. These include: (i) complete replacement of *R. decoloratus* by *R. microplus*, resulting in a national and probably regional upsurge of *R. microplus* populations; (ii) emergence of acaricide-resistant *R. microplus* populations; and (iii) a proportional increase of bovine babesiosis given that *R. microplus* is an efficient vector of *B. bovis* [11, 26, 32]. Unless effective national acaricide and animal movement control policies are instituted, the Ugandan livestock sector will suffer severe losses due to the direct effects of *R. microplus* infestation and bovine babesiosis.

Conclusions

It was expected to find *R. decoloratus* among other tick species on cattle during a survey conducted in south-eastern Uganda. Instead, we discovered that *R. microplus* has completely displaced *R. decoloratus* in the six villages studied, an indigenous tick species previously known to this region. There is a need to determine the extent of spread of *R. microplus* throughout Uganda and to put in place effective control measures considering that *R. microplus* is capable of developing high levels of resistance towards the major classes of acaricides.

Acknowledgements

The authors wish to acknowledge the District Veterinary Officer of Serere District, Dr Amony Collins for his help during tick collection. We also acknowledge the cattle owners and local council leaders of the six villages where this study was carried out for offering their cattle and helping with their restraint in this study. We are very grateful to Dr Bigirwa Godfrey, Kakooza Stephen, Dr Bbiira Jonson, Dr Omaido Edward, Gloria Grace Akurut and Dr Akech Olivia for their help during tick collection and field tick identification to genus level.

Authors' contributions

DM, JF, MM, TS, IH, NJ and FI conceived and designed the study. DM, JB, CN, WA, SO, JN and FI collected tick samples and performed taxonomic and molecular tick identification. DM, CN, SO, JN, FNMA and RT undertook molecular confirmation of *R. microplus*. DM, FNMA, RT, JF, MM, IH and FI drafted and critically reviewed this manuscript. All authors read and approved the final manuscript.

Funding

This study received funding from the Bill & Melinda Gates Foundation (BMGF) (Grant OPP1125367) through ClinVet International (Pty) (project no. CV 16/337). This work was also supported by the Makere University-Uganda Virus Research Institute Centre of Excellence for Infection and Immunity Research and Training (MUII). MUII is supported through the DELTAS Africa Initiative (Grant no. 107743). The DELTAS Africa Initiative is an independent funding scheme of the African Academy of Sciences (AAS), Alliance for Accelerating Excellence in Science in Africa (AESA), and supported by the New Partnership for Africa’s Development Planning and Coordinating Agency (NEPAD Agency) with funding from the Welcome Trust (Grant no. 107743) and the UK government. All funders of this research had no role in the design of the study, collection, analysis, and interpretation of data and in writing of this manuscript. The views expressed in this publication are those of the authors and not BMGF, MUII, African Academy of Science (AAS), NEPAD Agency, Welcome Trust and the UK government.

Availability of data and materials

Data supporting the conclusions of this article are included within the article. The newly generated sequences were submitted to the GenBank database under the accession numbers MK332390, MK332391, KY688455, KY688459, KY688461 and KY688467. The datasets used and/or analysed during the present study are available from the corresponding author upon reasonable request.

Ethics approval and consent to participate

Written informed consent was obtained from cattle owners. Cattle restraint, tick collection, preservation, morphological and molecular analyses followed highest veterinary care and scientific standards as approved (SLS/REC/16/136) by the Research and Ethics Committee of Makerere University School of Biosecurity, Biotechnical and Laboratory Sciences and the Uganda National Council of Science and Technology (A 513).

Consent for publication

Not applicable.

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
