Double Perovskites | Hot Paper |

Experimental and Theoretical Investigation of the Structural and Opto-electronic Properties of Fe-Doped Lead-Free Cs$_2$AgBiCl$_6$ Double Perovskite

Sachin Thawarkar$^{[a]}$, Sachin R. Rondiya$^{[b]}$, Nelson Y. Dzade$^{[b]}$, Nageshwar Khupse$^{[c]}$, and Sandesh Jadkar$^{[a]}$

Abstract: Lead-free double perovskites have emerged as stable and non-toxic alternatives to Pb-halide perovskites. Herein, the synthesis of Fe-doped Cs$_2$AgBiCl$_6$ lead-free double perovskites are reported that display blue emission using an antisolvent method. The crystal structure, morphology, optical properties, band structure, and stability of the Fe-doped double perovskites were investigated systematically. Formation of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite is confirmed by X-ray diffraction (XRD) and X-ray photoelectron spectroscopy (XPS) analysis. XRD and thermo-gravimetric analysis (TGA) shows the Cs$_2$AgBiCl$_6$ double perovskite has high structural and thermal stability, respectively. Field emission scanning electron microscopy (FE-SEM) analysis revealed the formation of dipyramidal shape Cs$_2$AgBiCl$_6$ crystals. Furthermore, energy-dispersive X-ray spectroscopy (EDS) mapping shows the overlapping of Cs, Bi, Ag, Fe, and Cl elements and homogenous incorporation of Fe in Cs$_2$AgBiCl$_6$ double perovskite. The Fe-doped Cs$_2$AgBiCl$_6$ double perovskite shows a strong absorption at 380 nm. It extends up to 700 nm, suggesting that sub-band gap states transition may originate from the surface defect of the doped perovskite material. The radiative kinetics of the crystals was studied using the time-correlated single-photon counting (TCSPC) technique. Lattice parameters and band gap value of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskites predicted by the density functional theory (DFT) calculations are confirmed by XRD and UV/Visible spectroscopy analysis. Time-dependent photo-response characteristics of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite show fast response and recovery time of charge carriers. We believe that the successful incorporation of Fe in lead-free, environmentally friendly Cs$_2$AgBiCl$_6$ double perovskite can open a new class of doped double perovskites with significant potential opto-electronics devices fabrication and photocatalytic applications.

Introduction

Lead halide A$^+$Pb$^+$X$_n$ (A = CH$_3$NH$_3$, Cs; X = Cl, Br, I) perovskites have been established as efficient materials for photovoltaic (PV) and opto-electronic applications with certified power conversion efficiencies (PCEs) exceeding 23%. This has been attributed mainly to their outstanding intrinsic high absorption coefficient, suitable band gap, and high charge carrier mobility. Despite these wonderful properties and demonstrated high PCEs, the large scale deployment of these materials is limited by the lead contents toxicity and the intrinsic thermal and moisture instability. Significant efforts have been made to reduce the toxicity issues and improve the stability of lead halide perovskites. Various strategies have been designed and developed for the replacement of Pb. One such approach is replacing the Pb with the substitution of group IV metals with less toxicity, such as Ge$^{2+}$ and Sn$^{2+}$. Unfortunately, these elements' chemical stability is poor because they undergo facile oxidation from 2+ states to 4+ oxidation states. Another promising approach is hetero-valent metal substitution. In this approach, two divalent Pb$^{2+}$ ions are replaced with a pair of one trivalent B$^{3+}$ and monovalent B$^+$ cation, leading to the formation of A$_n$B$^8$X$_6$ double perovskite materials, which persist the 3D crystal structure and the charge neutrality of perovskite. Furthermore, incorporating another new element into the double perovskite structure guides the optical...
and structural properties depending on chemical compositions.\textsuperscript{24} Inorganic double perovskites $A_B B'OX_3$ having variants $A = \text{Cs}$, $B' = \text{Ag}$, $\text{Na}$, $K$, $\text{Li}$; $B'' = \text{Bi}$, $\text{Sb}$, $\text{In}$; $X = \text{Cl}$, $\text{Br}$, $I$ show an alternating arrangement of $B'$ and $B''$ ions on the octahedral sites (rock salt).\textsuperscript{25–26} Therefore, double perovskites materials are more attractive as they do not contain toxic $\text{Pb}^{2+}$ ions and have good thermal and chemical stability and band gap tunability. For example, bismuth halide double perovskites such as $\text{Cs}_2\text{AgBiCl}_6$ and $\text{Cs}_2\text{AgBiBr}_6$ have indirect band gaps of 2.77 eV and 1.95 eV, respectively.\textsuperscript{30–34} Bandgap tunability has also been achieved by doping $\text{Mn}^{2+}$, $\text{Sb}^{3+}$, and $\text{In}^{3+}$ into the $\text{Cs}_2\text{BiAgCl}_6$ lattice.\textsuperscript{35–38} For example, Locardi et al.\textsuperscript{35} have reported high photoluminescence quantum yield (PLQY) and improved the visible light emission properties for Mn-doped $\text{Cs}_2\text{AgInCl}_6$. This demonstrates that doping is an effective technique to achieve superior opto-electronic properties and reduced defect state density in double perovskites. Both are essential to fabricate highly efficient opto-electronic devices. There are, however, limited studies dedicated to the comprehensive characterization of the absorption, emission, recombination dynamic processes in double perovskites. In the present study, we report the synthesis of a high-quality, lead-free, and low-cost Fe-doped $\text{Cs}_2\text{AgBiCl}_6$ double perovskite via a solvent method. The absorption, emission, and recombination dynamic properties were compressively characterized using time-resolved photoluminescence spectroscopy (TR-PL). Photoconductivity measurements under visible light with a standard photoelectrochemical (PEC) cell arrangement, demonstrates that the Fe-$\text{Cs}_2\text{AgBiCl}_6$ samples exhibit high photocurrent. The prepared double perovskite materials not only retain their optical properties, but also show good thermal and electronic stability, which are helpful to make devices. This work provides novel insights into the structure-property relationships in lead-free double perovskites and offers new strategies for the development of advanced perovskite devices.

**Experimental Section**

**Materials and chemicals**

Cesium(II) chloride ($\text{CsCl}$, Sigma Aldrich, 99%), silver(I) chloride ($\text{AgCl}$, Sigma Aldrich, 99.99%), bismuth(III) chloride ($\text{BiCl}_3$, Sigma Aldrich, 99.9%), dimethyl sulfoxide (DMSO, Sigma Aldrich, 99.9%) and isopropanol (Sigma Aldrich 99.9%). All the precursors were used as received without further purifications.

**Synthesis of $\text{Cs}_2\text{AgBiCl}_6$ and Fe-doped $\text{Cs}_2\text{AgBiCl}_6$ double perovskite**

Undoped and Fe-doped $\text{Cs}_2\text{AgBiCl}_6$ double perovskites were synthesized using the solvent method. The schematic representation of the synthesis protocol used for the synthesis is shown in Scheme S2 (Supporting Information). For the undoped sample, 0.2 mmol (101.1 mg) $\text{CsCl}$, 0.1 mmol (42.9 mg) $\text{AgCl}$ and 0.1 mmol (94.5 mg) $\text{BiCl}_3$ were dissolved in 5 mL DMSO to form a precursor solution. After that, under vigorous stirring, 100 $\mu$L of the precursor solution was injected into 5 mL isopropanol. The mixed solution was then centrifuged at 3000 rpm for 3–6 min to remove large crystals. For the doped samples, $\text{FeCl}_3$ was used as the Fe precursor. For 3% and 6% doping of Fe into $\text{Cs}_2\text{AgBiCl}_6$, double perovskites, 0.006 mm (2.84 mg) and 0.012 mm (5.68 mg) $\text{FeCl}_3$ was taken along with the rest of the precursors, respectively. The protocol for the synthesis of doping was similar as described above.

**Characterization of $\text{Cs}_2\text{AgBiCl}_6$ and Fe-doped $\text{Cs}_2\text{AgBiCl}_6$ double perovskite**

UV/Visible spectra of the undoped and Fe doped $\text{Cs}_2\text{AgBiCl}_6$ double perovskites were recorded using UV-1800 spectrophotometer (SHIMADZU, Japan) in isopropanol. The surface morphology and shape of the Fe doped $\text{Cs}_2\text{AgBiCl}_6$ double perovskite material were investigated under field emission scanning electron microscopy (FE-SEM) using FEI Nova NanoSEM 450, EDS: Bruker X Flash 6130 instrument. Samples were made via drop-casting on the silicon wafer and dried under reduced pressure for 12 h. Transmission electron microscopy (TEM) images were obtained from high-resolution transmission electron microscopy (HR-TEM) TALOS F-200x; a drop of the sample was placed on a carbon-coated copper grid dried in the dark for the night. The powdered X-ray diffraction (XRD) patterns were measured on XRD, Bruker AXS D8 Advance using Cu Ka radiation within a range of 20–80°. Thermogravimetric analysis (TGA) was recorded using a TGA-50 Shimadzu under nitrogen atmosphere. The experiment was performed from 30 to 1000 °C with a heating rate of 10 °C/min.\textsuperscript{11} Time-resolved photoluminescence (TRPL) spectra were measured using a time-correlated single-photon counting (TCSPC) system by Edinburgh EPLED-330. X-ray photoelectron spectroscopy (XPS) studies were carried out using Thermo Scientific, K-Alpha \textsuperscript{+}, UK machine with a resolution of 0.1 eV. The machine can achieve vacuum $>10^{-7}$ torr, and we have recorded XPS spectra for the specific element using Al Kα (1486.6 eV) radiation. The XPS signals were obtained after several scans deployed in the acquisition process. The binding energy was corrected for specimen charging through referencing C 1s to 284.6 eV. The photo-response of the Fe doped $\text{Cs}_2\text{AgBiCl}_6$ double perovskite was performed using a conventional 3-electrode system.

**Density functional theory (DFT) details**

The electronic structure calculations were performed using density functional theory (DFT) within periodic boundary conditions as implemented in the Vienna Ab initio Simulation Package (VASP).\textsuperscript{39–41} The Perdew–Burke–Ernzerh of (PBE) functional\textsuperscript{42} was used for geometry optimizations and stability, while for electronic structures and optical calculations, the screened hybrid functional HSE06 with 25% Hartree–Fock exchange was used, with the addition of spin-orbit effects (HSE06 + SOC).\textsuperscript{43} The valence and core electrons interactions were described with the projected augmented wave (PAW) method.\textsuperscript{44} A $3\times3\times3$ I-centered Monkhorst–Pack\textsuperscript{45} $k$-mesh and a 600 eV plane-wave cut off were used for structure optimization, while a tighter $k$-mesh of $5\times5\times5$ was used for the electronic structure calculations.

**Photoelectrochemical (PEC) cell assembly**

Scheme S1 in the Supporting Information shows the schematic of the PEC cell employed in the present study. Three electrodes were placed inside the cell; synthesized Fe-doped $\text{Cs}_2\text{AgBiCl}_6$ double perovskite film act as working electrode (WE), whereas platinum foil and saturated calomel electrode (SCE) were used as a counter electrode (CE) and a reference electrode (RE), respectively. 0.2 m $\text{Na}_2\text{SO}_4$ was used as the electrolyte. Results and Discussion

X-ray diffraction (XRD) analysis

To perform the synthesis of Fe-doped Cs$_2$AgBiCl$_6$ double perovskite at room temperature, we implemented a modified antisolvent method, which avoids the conventional heating, injection methods, and inert gas conditions. Scheme S2 (Supporting Information) shows the actual photographs of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite under ordinary light and blue emission at 365 nm UV light excitation. A Cs$_2$AgBiCl$_6$ double perovskite is composed of Cs$^+$ ion at the center of cubicoctahedra with alternating [BiCl$_6$]$^{3-}$ and [AgCl$_6$]$^{3-}$ octahedral unit, which leads to the formation of a 3D network.[31] Figure 1a shows the XRD pattern of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite. The presence of multiple diffraction peaks indicates that the Fe-doped double perovskites are polycrystalline. Major diffraction peaks are observed in the XRD pattern at $2\theta = 23.63^\circ$, $33.36^\circ$, $41.27^\circ$, $47.98^\circ$, $54.00^\circ$, and $59.60^\circ$, which correspond to (220), (400), (422), (440), (620) and (444) diffraction planes of standard cubic double perovskite structure with a Fm3m space group and lattice parameter $a = 10.91\ \text{Å}$. These results are consistent with previous literature reports,[20,21,27] confirming the formation of Fe doped and undoped Cs$_2$AgBiCl$_6$ double perovskite via the antisolvent method. A careful analysis of the XRD pattern of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite reveals a shift of all diffraction peaks towards a higher diffraction angle and a subsequent increase in the diffraction intensity with increasing Fe doping concentration. For example, the (400) diffraction peak is shifted by 0.63$^\circ$ and 0.90$^\circ$ relative to the undoped Cs$_2$AgBiCl$_6$ double perovskite for 3% and 6% Fe-doping, respectively (see Figure 1b). The shifts in diffraction peak and the increasing intensity indicate that the incorporation of smaller Fe$^{3+}$ ion (0.63 Å) in place of larger Bi$^{3+}$ ion (1.03 Å) induces contractions in the lattice. The lattice parameter contracted from 10.91 Å for the undoped to 10.67 Å and 10.60 Å for the 3% and 6% Fe-doped Cs$_2$AgBiCl$_6$. We have observed an XRD peak at 46.42$^\circ$ in the 3% Fe-doped Cs$_2$AgBiCl$_6$ samples, which may be due to AgCl. The diffraction intensity of all the Fe-doped samples is significantly high. The full width at half-maximum is narrower, suggesting that the Fe-doped double perovskites have excellent crystallinity. The interplanar $d$-spacings ($d$) calculated from the diffraction peak positions ($2\theta$) of the different diffraction planes (hkl) for the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite are displayed in Table S1 in the Supporting Information. It shows the clear differences between the structural properties (crystallite size, strain, interplanar distance, and lattice parameters) of the pristine, 3%, and 6% doping of Fe into Cs$_2$AgBiCl$_6$ double perovskites (Table 1). The contraction in the $d$-values for the 3% and 6% Fe-doped Cs$_2$AgBiCl$_6$ double perovskites relative to the undoped counterpart indicates the successful doping of Fe into Cs$_2$AgBiCl$_6$ double perovskite. We think that with Fe$^{3+}$ doping, the [BiCl$_6$]$^{3-}$ octahedra may be replaced by [FeCl$_6$]$^{3-}$ octahedra in the Cs$_2$AgBiCl$_6$ double perovskite lattice. There are three possibilities by which Fe$^{3+}$ ion can incorporate into a Cs$_2$AgBiCl$_6$ crystal lattice. In Cs$_2$AgBiCl$_6$ double perovskite, [BiCl$_6$]$^{3-}$ octahedra, [AgCl$_6$]$^{3-}$ octahedra and Cs$^+$ ion of A-site can be replaced by [FeCl$_6$]$^{3-}$ octahedra leading to the formation Fe-doped Cs$_2$AgBiCl$_6$ lattice. However, due to the large electronegativity difference between Fe (1.83) and Cs (0.79) as well as the charge difference between Fe (3+) and Cs (+), the possibility of replacement of Cs by Fe ion in Cs$_2$AgBiCl$_6$ lattice is ruled out. On the other hand, the electronegativity of Cs is close to that of Ag (1.93) and Bi (2.0) and the charge balance is significantly maintained by Bi$^{3+}$ and Fe$^{3+}$ compared to that of Bi$^{3+}$ and Ag$^+$, therefore [FeCl$_6$]$^{3-}$ octahedra is expected to replace the [BiCl$_6$]$^{3-}$ octahedra is more dominant in the formation of Fe-doped Cs$_2$AgBiCl$_6$ lattice.

To investigate the structural stability of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskites, XRD measurements were carried out after six months on the same samples after exposing them to ambient environmental conditions without any encapsulation. Figure 1c shows the XRD pattern of the undoped and Fe-doped Cs$_2$AgBiCl$_6$ samples taken after six months of exposure under normal temperature and pressure. Figure 1d shows the zoomed-in XRD patterns for

![Figure 1a](image1.png) ![Figure 1b](image2.png) ![Figure 1c](image3.png) ![Figure 1d](image4.png)

Figure 1. (a) XRD pattern for undoped and Fe-doped Cs$_2$AgBiCl$_6$ double perovskites with different Fe concentrations, (b) Shifting of $2\theta$ degree of (400) plane, (c) XRD pattern of undoped and Fe-doped Cs$_2$AgBiCl$_6$ double perovskites with different Fe concentrations taken after six months exposure under normal temperature and pressure and (d) Zoomed-in XRD patterns for clear visualization of (400) diffraction peak.
clear visualization of the (400) diffraction peak. It has been observed that there is no significant change in diffraction intensity of all diffraction peaks, as well as no significant change or shift in the diffraction angles after six months of ambient exposure of the Fe-doped Cs$_2$AgBiCl$_6$ perovskite. These results suggest that the Fe-doped Cs$_2$AgBiCl$_6$ nanocrystals have excellent stability after six months of exposure to ambient environmental conditions.

Thermo-gravimetric analysis (TGA)

The thermal and chemical stability of perovskite materials is an important parameter to evaluate their ability for device applications. To investigate the thermal stability of Fe-doped Cs$_2$AgBiCl$_6$ perovskite, TGA was carried out. Temperature-dependent weight loss of the undoped and Fe-doped Cs$_2$AgBiCl$_6$ double perovskites is shown in Figure 2. As seen, the weight loss of the Fe-doped double perovskites is found in two steps. The first step of weight loss starts around 510–715°C with 22 wt.% and the second significant weight loss is observed at about 78 wt.%, which mainly takes place from 715–1000°C. It can be seen from the thermo-gram that the Fe-doped Cs$_2$AgBiCl$_6$ perovskites are highly stable until 510°C and the decomposition starts above 510°C. This result indicates that Fe-doped Cs$_2$AgBiCl$_6$ double perovskites have excellent thermal stability.

Table 1. Crystallite size, strain, interplanar distance, and lattice parameters of pristine, 3%, and 6% doping of Fe into Cs$_2$AgBiCl$_6$ double perovskites.

| Sample              | Crystallite size [nm] | Strain | $d_{111}$ [Å] | $a = b = c$ [Å] |
|---------------------|-----------------------|--------|--------------|-----------------|
| Pristine Cs$_2$AgBiCl$_6$ | D$_1$ = 48.76         | S$_1$ = 3.59 x 10$^{-1}$ | $d_1$ = 3.89 | $a_1 = b_1 = c_1$ = 11.00 |
| 3% of Fe doped Cs$_2$AgBiCl$_6$ | D$_2$ = 37.76         | S$_2$ = 3.25 x 10$^{-1}$ | $d_2$ = 2.73 | $a_2 = b_2 = c_2$ = 10.91 |
| 6% of Fe doped Cs$_2$AgBiCl$_6$ | D$_3$ = 48.83         | S$_3$ = 3.16 x 10$^{-1}$ | $d_3$ = 3.76 | $a_3 = b_3 = c_3$ = 10.63 |
| D$_4$ = 43.68       | S$_4$ = 3.43 x 10$^{-1}$ | $d_4$ = 2.68 | $a_4 = b_4 = c_4$ = 10.67 |
| D$_5$ = 39.57       | S$_5$ = 3.02 x 10$^{-1}$ | $d_5$ = 2.65 | $a_5 = b_5 = c_5$ = 10.60 |

Figure 2. Thermo-gravimetric analysis (TGA) of undoped and Fe-doped Cs$_2$AgBiCl$_6$ double perovskites for testing the thermal stability.

X-ray photoelectron spectroscopy (XPS) analysis

Quantitative analysis of the electronic structures and chemical properties of Fe-doped Cs$_2$AgBiCl$_6$ double perovskite has been performed by XPS analysis. Figure 3a illustrates the survey and high-resolution XPS spectra of Fe-doped Cs$_2$AgBiCl$_6$ double perovskite. As seen, the peaks corresponding to cesium [Cs(3d)], silver [Ag (3d)], bismuth [Bi (4f)], chlorine [Cl (2p)] and iron [Fe (2p)] appear in the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite. Figure 3b-f are the narrow scan XPS spectra for 3d-Cs, 3d-Ag, 4f-Bi, 2p-Cl and 2p-Fe elements, respectively. In Figure 3b, two strong peaks were observed for the narrow XPS spectra of 3d-Cs. The peak at 728.1 eV is due to 3d$_{5/2}$-Cs and peak at 742.1 eV due to 3d$_{3/2}$-Cs consistent with the standard Cs element. The two peaks were disjoint with an energy value of 14.0 eV. The 3d-Ag spectra consist of two peaks at 371.7 and 377.6 eV associated with Ag 3d$_{5/2}$ and Ag 3d$_{3/2}$, respectively. The core-level peaks for Bi are found at the binding energy 163.0 eV due to Bi 4f$_{1/2}$ and 168.5 eV due to 4f$_{3/2}$. The energy separation between these two peaks was measured 5.5 eV, which is a characteristic signal from the Bi$^{3+}$ species (Figure 3d). The 2p-Cl spectra composed of two peaks at 202.0 and 203.7 eV originating from Cl 2p$_{3/2}$ and Cl 2p$_{1/2}$, respectively (Figure 3e). Figure 3f shows the 2p-Fe XPS spectra of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite material. The 2p-Fe has two peaks with binding energies 710.78 and 724.10 eV which are related to Fe 2p$_{1/2}$ and 2p$_{3/2}$, respectively. The binding energy of all the elements is slightly shifted at higher values than the reported one, demonstrating that the stronger M-Cl interaction in the [BiCl$_6$]$^{3-}$/[AgCl$_6$]$^{3-}$ octahedra and leads to differing the chemical environment around Bi, Ag, and Cs on Fe-incorporation. The results are analogous to that of earlier reported systems.$^{46–48}$ These results confirm the effective doping of Fe in Cs$_2$AgBiCl$_6$ double perovskite material. The XPS spectra of the pristine Cs$_2$AgBiCl$_6$ and 3% Fe-doped double perovskite are provided in Figures S1 and S2 in the Supporting Information.

Electron microscopy analysis

Field emission scanning electron microscope (FE-SEM) and transmission electron microscope (TEM) were used to study surface morphology and topography of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite. The FE-SEM images of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite at different resolutions are shown in Figure 4a1–a3. It shows the formation of micrometer-sized multifaceted crystals, including several uniform dipyramidal units having a size of 1–2 μm. A close-up picture in the magnified images for one microcrystal (Figure 4c) shows perfect dipyramidal units with a cubic crystal system. The fine fac-
eted microcrystal confirmed the double perovskite material is formed with high crystallinity. Figure 4b1 and Figure 4b2 shows low-resolution transmission electron microscopy (LR-TEM) and high-resolution TEM (HR-TEM) images of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskites, respectively. The inset in Figure 4b2 is an enlarged area “A” view of the HR-TEM image, which shows that the inter-planar spacing between two adjacent lattice planes of the Fe-doped Cs$_2$AgBiCl$_6$ perovskite to be 0.228 nm, which is consistent with the spacing of the (422) plane of Fe-doped Cs$_2$AgBiCl$_6$ double perovskite crystal. These results are also consistent with the X-ray diffraction results (see Table S3). Figure 4b3 is the selected area electron diffraction (SAED) pattern of Fe-doped Cs$_2$AgBiCl$_6$ double perovskite. The bright diffraction spots in the SAED reveal the polycrystalline nature of the Fe-doped Cs$_2$AgBiCl$_6$ perovskite with a high degree of crystallinity.
Energy-dispersive X-ray spectroscopy (EDS) analysis

The compositional analysis of Fe-doped Cs₂AgBiCl₆ double perovskite was carried out using Energy Dispersive X-ray Analysis (EDS) technique. A typical EDS spectrum recorded in the binding energy region of 0–10 KeV for the Fe-doped Cs₂AgBiCl₆ double perovskite is shown in Figure 5a. The EDS mapping (Figure 5b, 5c, 5d, 5e, and 5f) shows the overlapping of Cs, Ag, Bi, Cl, and Fe elements, respectively. It indicates that Fe is homogeneously incorporated in the entire Cs₂AgBiCl₆ double perovskite lattice. EDS pattern of the elements displays peaks at 0.7 and at 6.4 keV, which confirms the presence of Fe in the crystal lattice.

Optical properties

UV/Visible absorption spectroscopy was used to investigate the optical properties and light absorption capability of the Fe-doped Cs₂AgBiCl₆ double perovskite. Figure 6a shows the room-temperature absorption spectra of the undoped and Fe-doped Cs₂AgBiCl₆ double perovskite. Fe-doped Cs₂AgBiCl₆ double perovskite samples reveal a sharp absorption peak with the first electronic transition peak at 373 nm (3.31 eV) and 380 nm (3.27 eV). The absorption peak also shows a long tail extended to 700 nm, which suggests that the transition from sub-band gap states may originate from the surface defect of the Fe-doped Cs₂AgBiCl₆ double perovskite material. The absorption spectra of the Fe-doped Cs₂AgBiCl₆ double perovskite reveal a small change in peak positions and shapes. It is consistent with the point that the 6s→6p transition of the Bi³⁺ ions largely directed the first electronic transition of Fe-doped Cs₂AgBiCl₆ microcrystal.²⁰,³⁷ The absorption peak suggests negligible perturbations in the electronic structure of Cs₂AgBiCl₆ when Fe²⁺ is incorporated into the lattice. The UV/Visible spectra are used to estimate the optical band gap of Fe-doped Cs₂AgBiCl₆ perovskite. Absorbance and incident photon energy can be directly related using equation,²⁰

\[(ahv)^{1/2} = C (hv - E_g)\]  

(1)

in which h is Planck’s constant, α is the absorption coefficient, ν is the frequency of light, C is the proportionality constant, E₉ is the band gap, and n is integer 1/2 or 2 depending on the material and whether it is a direct or indirect band gap. The inset of Figure 6a shows the typical Tauc’s plot for Fe-doped Cs₂AgBiCl₆ double perovskite used for the estimation of the optical band gap. The indirect band gap of the Fe-doped Cs₂AgBiCl₆ double perovskite is estimated at 2.45 eV, whereas the pristine Cs₂AgBiCl₆ has an indirect band gap of 2.77 eV. The band gap reduction after Fe-doping may be due to the overlap of the Ag-d/Cl-p orbital and the Fe-3d orbital during the construction of the valence band and new VBM shifting towards a higher energy level as revealed by DFT calculations (Figure 8). A similar result has been observed in Cu-doped Cs₂AgInCl₆, Sb-doped Cs₂AgBiBr₆, and Ti-doped Cs₂AgBiBr₆.⁴⁸,⁵⁰ The decrease in band gap suggests that the Fe-doped Cs₂AgBiBr₆ double perovskite material is a more suitable absorber for tandem solar device applications. We examined the photophysical properties and determined the Urbach energy (Eₚ) of Fe-doped double perovskite materials. It shows structural disorders, effects of impurities, and electron-phonon interactions in the absorption phenomenon.⁵¹

The Urbach energy is estimated by using,²⁵

\[\alpha = \alpha_0 \exp \left( \frac{hv}{E_p} \right)\]  

(2)

in which α is the absorption coefficient, and hv is the photon energy. The Urbach energy is then estimated by plotting ln(α)
as a function of \((h\nu)\) shown in Figure S3 (Supporting Information). The reciprocal of the slope of a linear fit gives the value of Urbach energy. The Urbach energy for the undoped and Fe-doped Cs₂AgBiCl₆ is found to be 1.2 eV and 1.0 eV, respectively.

To further insights into the optical properties of doped Cs₂AgBiCl₆ double perovskite material, time-resolved photoluminescence (TRPL) analysis has been carried out. Figure 6c shows the time-resolved photoluminescence emission spectra for Fe-doped Cs₂AgBiCl₆ double perovskite materials in isopropanol using a laser excitation wavelength of 412 nm. The TRPL traces at 412 nm wavelength show an initially fast decay, followed by a slow decay with a tail. The PL decay time of the Fe-doped Cs₂AgBiCl₆ double perovskite is reduced as compared to the undoped Cs₂AgBiCl₆ double perovskite materials. It may be the enhancement in the non-radiative recombination rate. The emission decay traces can be well fitted to bi-exponential function,

\[
A(t) = A_1 \exp\left(-\frac{t}{\tau_1}\right) + A_2 \exp\left(-\frac{t}{\tau_2}\right)
\]

in which \(\tau_1\) and \(\tau_2\) are the decay constants for the fast and slow components of the traces, respectively. The short-lived component \(\tau_1\) and a long-lived component \(\tau_2\) are estimated at 1.71 ns and 9.41 ns at 412 nm excitation wavelength. The calculated kinetic parameters are displayed in Table 2. The average carrier lifetime for the Fe-doped Cs₂AgBiCl₆ double perovskite at excitation wavelength 412 nm is in the order of 8.41 ns. It is reported that the biexponential decay corresponds to two different phenomena. First, the short life-time PL component is due to the recombination of initially generated excitons, while the second is the long-life time PL attributed to recombination of excitons during the contribution of surface states, which act as stable excitons at room temperature. However, more investigation is necessary to get additional insights into the phenomenon of exciton dynamic.

### Photo-response properties

The photoelectrochemical (PEC) experimentation of Fe-doped Cs₂AgBiCl₆ double perovskite was carried out using linear sweep current density–voltage (\(J–V\)) technique under dark and light visible light irradiation. Figure 7a shows the current density–voltage \((J–V)\) curves for the Fe-doped Cs₂AgBiCl₆ double perovskite under dark and visible light illumination. A significant increase in the negative current under visible light illumination for the Fe-doped Cs₂AgBiCl₆ double perovskite is observed. Figure 7b shows the time-dependent current response of the Fe-doped Cs₂AgBiCl₆ double perovskite for repeated
cycles under dark and white light illumination at a constant bias voltage $-0.4$ V. Sharp rise and decay of the photocurrent has been observed when the light is turned ON and OFF. The rapid increase of photocurrent density $3 \mu A/cm^2$ has been observed after illumination for Fe-doped Cs$_2$AgBiCl$_6$ double perovskite photoelectrode and is recovered rapidly in dark conditions. Figure 7c shows a single-cycle of time-dependent current response of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite J–T curve using white light illumination to measure the response and recovery time of charge carriers. The response and recovery time for the charge carrier of Fe-doped Cs$_2$AgBiCl$_6$ double perovskite material is found 1.94 s and 1.57 s, respectively. The fast response and recovery of charge carrier for the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite thin films under white light illumination make them suitable for various opto-electronics applications, photocatalysts, and photovoltaics as environmentally friendly halide double perovskites.

Density functional theory (DFT) analysis

The experimental results were corroborated by first-principles density functional theory (DFT) calculations. The optimized structures of the undoped and Fe-doped Cs$_2$AgBiCl$_6$ materials in the cubic crystal structure (Fm$ar{3}$m space group) are shown in Figure 8. The lattice parameters are 10.885 Å for pristine Cs$_2$AgBiCl$_6$ and 10.782 Å for the Fe-doped Cs$_2$AgBiCl$_6$, which indicate that Fe substitutional doping at Bi site results in contraction of the lattice, owing to the smaller ionic radius of Fe$^{3+}$ ion (0.63 Å) than Bi$^{3+}$ ion (1.03 Å). The calculated lattice parameters are consistent with the values estimated by XRD analysis. The band structures (Figure 8c and Figure 8d) reveal indirect band gaps, predicted at 2.75 eV and 2.51 eV, respectively, for the undoped and Fe-doped Cs$_2$AgBiCl$_6$ double perovskites. The DFT predicted band gap values for undoped and Fe-doped Cs$_2$AgBiCl$_6$ double perovskites are consistent with those obtained from UV/Visible spectroscopy analysis. The substitution
of Bi by Fe resulted in the introduction of donor states close to the top of the valence band. The partial density of states (PDOS) plots (Figure 8e and Figure 8f) shows that the valence band to be composed mainly of CI-p orbitals, whereas the conduction band is composed more of Bi-p orbitals.

Conclusions

We have successfully synthesized Fe-doped Cs$_2$AgBiCl$_6$ double perovskite that displays blue emission via an antisolvent method. The formation of Fe-doped Cs$_2$AgBiCl$_6$ double perovskite is confirmed by XRD and XPS analyses. XRD pattern of the Cs$_2$AgBiCl$_6$ perovskite recorded after six months of exposure to ambient environmental conditions shows that the material has high structural stability. Also, TGA results indicate that both Fe-doped Cs$_2$AgBiCl$_6$ perovskites have high thermal stability (510 °C). FE-SEM analysis revealed the formation of a pyramidal-dipiramidal shape in Fe-doped Cs$_2$AgBiCl$_6$ double perovskite and EDS mapping shows the overlapping of Cs, Bi, Ag, Fe, and Cl elements, with the Fe homogeneously incorporated in the entire Cs$_2$Bi$_2$AgCl$_6$ perovskite lattice. The Fe-doped Cs$_2$AgBiCl$_6$ double perovskite shows a sharp absorption peak at 380 nm and extends up to 700 nm suggesting the transition from sub-bandgap states may originate from the surface defect of Fe-doped Cs$_2$AgBiCl$_6$ perovskite material. Lattice parameters and band gap values of the Fe-doped Cs$_2$AgBiCl$_6$ double perovskites predicted by the DFT calculations are confirmed by XRD and UV/Visible spectroscopy analysis. Finally, time-dependent photoresponse characteristics for Fe-doped Cs$_2$AgBiCl$_6$ double perovskite show fast response and recovery time of charge carriers. The displayed high thermal stability and excellent response and recovery time of charge carriers in the Fe-doped Cs$_2$AgBiCl$_6$ double perovskite make it a suitable lead-free solar absorber for various opto-electronics applications, including photocatalysis and photovoltaics.
