Keywords: damped wave equation, semilinear, blow-up
MSC2010: primary 35L71, secondary 35B44

Abstract

The blow-up for semilinear wave equations with the scale invariant damping has been well-studied for sub-Fujita exponent. However, for super-Fujita exponent, there is only one blow-up result which is obtained in 2014 by Wakasugi in the case of non-effective damping. In this paper we extend his result in two aspects by showing that: (I) the blow-up will happen for bigger exponent, which is closely related to the Strauss exponent, the critical number for non-damped semilinear wave equations; (II) such a blow-up result is established for a wider range of the constant than the known non-effective one in the damping term.

1 Introduction

In this paper, we consider the following initial value problem.

\[
\begin{align*}
  u_{tt} - \Delta u + \frac{\mu}{1+t} u_t &= |u|^p & \text{in } \mathbb{R}^n \times [0, \infty), \\
  u(x, 0) &= \varepsilon f(x), \quad u_t(x, 0) &= \varepsilon g(x), & x \in \mathbb{R}^n,
\end{align*}
\]  \tag{1.1}

where \(\mu > 0\), \(f, g \in C_0^\infty(\mathbb{R}^n)\) and \(n \in \mathbb{N}\). We assume that \(\varepsilon > 0\) is a “small” parameter.

First, we shall outline a background of (1.1) briefly according to the classifications by Wirth in [20, 21, 22] for the corresponding linear problem. Let \(u^0\) be a solution of the initial value problem for the following linear damped wave equation.

\[
\begin{align*}
  u_{tt}^0 - \Delta u^0 + \frac{\mu}{(1+t)^\beta} u_t^0 &= 0 & \text{in } \mathbb{R}^n \times [0, \infty), \\
  u^0(x, 0) &= u_1(x), \quad u_t^0(x, 0) = u_2(x), & x \in \mathbb{R}^n,
\end{align*}
\]  \tag{1.2}

where \(\mu > 0\), \(\beta \in \mathbb{R}\), \(n \in \mathbb{N}\) and \(u_1, u_2 \in C_0^\infty(\mathbb{R}^n)\). When \(\beta \in (\infty, -1)\), we say that the damping term is “overdamping” in which case the solution does not decay to zero when \(t \rightarrow \infty\). When \(\beta \in [-1, 1)\), the solution behaves like that of the heat equation, which means that the term \(u_{tt}^0\) in (1.2) has no influence on the behavior of the solution. In fact, \(L^p-L^q\) decay estimates of the solution which are almost the same as those of the heat equation are established. In this case, we say that the damping term is “effective.” In contrast, when \(\beta \in (1, \infty)\), it is known that the solution behaves like that of the wave equation, which means that the damping term in (1.2) has no influence on the behavior of the solution. In fact, in this case the solution scatters to that of the free wave equation when \(t \rightarrow \infty\), and thus we say that we have “scattering.” When \(\beta = 1\), the equation in (1.2) is invariant under the following scaling

\[
\tilde{u}^0(x,t) := u^0(\sigma x, \sigma(1+t) - 1), & \sigma > 0,
\]

and hence we say that the damping term is “scale invariant.” The remarkable fact in this case is that the behavior of the solution of (1.2) is determined by the value of \(\mu\). Actually, for \(\mu \in (0, 1)\), it is known that the asymptotic behavior of the solution is closely related to that of the free wave equation. For this range of \(\mu\), we say that the damping term is “non-effective.” However, the threshold of \(\mu\) according to the behavior of the solution is still open. We conjecture that it may be \(\mu = 1\) since we have the following \(L^2\) estimates:

\[
\|u^0(\cdot,t)\|_{L^2} \lesssim \|u_1\|_{L^2} + \|u_2\|_{H^{-1}} \times \begin{cases} 
(1 + t)^{1-\mu} & \text{if } \mu \in (0, 1), \\
\log(e + t) & \text{if } \mu = 1, \\
1 & \text{if } \mu > 1.
\end{cases}
\]
In this way, we may summarize all the classifications of the damping term in (1.2) in the following table.

| $\beta$ | Classification          |
|---------|-------------------------|
| $\in (\infty, -1)$ | overdamping             |
| $\in [-1, 1)$ | effective               |
| $= 1$ | scaling invariant       |
| $\in (1, \infty)$ | non-effective $\mu \in (0, 1)$ scattering |

Next, we consider the following initial value problem for semilinear damped wave equation.

$$
\begin{align*}
\left\{
\begin{array}{l}
v_{tt} - \Delta v + \frac{\mu}{(1+t)^\beta}v_t = |v|^p, \quad \text{in } \mathbb{R}^n \times [0, \infty), \\
v(x, 0) = \varepsilon f(x), \quad v_t(x, 0) = \varepsilon g(x), \quad x \in \mathbb{R}^n,
\end{array}
\right.
\end{align*}
$$

(1.3)

where $\mu > 0$, $\beta \geq -1$, $f, g \in C^\infty_0(\mathbb{R}^n)$ and $n \in \mathbb{N}$. We assume that $\varepsilon > 0$ is a “small” parameter.

For the constant coefficient case, $\beta = 0$, Todorova and Yordanov [15] have shown that the energy solution of (1.3) exists globally-in-time for “small” initial data if $p > p_F(n)$, where

$$
p_F(n) := 1 + \frac{2}{n}
$$

(1.4)

is the so-called Fujita exponent, the critical exponent for semilinear heat equations. It has been also obtained in [15] that the solution of (1.3) blows-up in finite time for some positive data if $1 < p < p_F(n)$. The critical case $p = p_F(n)$ has been studied by Zhang [24] by showing the blow-up result.

We note that Li and Zhou [10], or Nishihara [12], have obtained the sharp upper bound of the lifespan which is the maximal existence time of solutions of (1.3) in the case of $n = 1, 2$, or $n = 3$, respectively. The sharpness of the upper bound has been studied by Li [11] including the result for more general equations with all $n \geq 1$, but for smooth nonlinear terms. The sharp lower bound has been obtained by Ikeda and Ogawa [6] for the critical case. Recently, Lai and Zhou [9] have obtained the sharp upper bound of the lifespan in the critical case for $n \geq 4$.

For the variable coefficient case of the most part of the effective damping with $-1 < \beta < 1$, Lin, Nishihara and Zhai [13] have obtained the blow-up result if $1 < p \leq p_F(n)$ and the global existence result if $p > p_F(n)$. Later, D’Abbicco, Lucente and Reissig [2] have extended the global existence result to more general equations. For the precise estimates of the lifespan in this case, see Introduction in Ikeda and Wakasugi [7]. Recently, similar results
on the remaining part of effective damping with $\beta = 1$ have been obtained
by Wakasugi [19] for the global existence part, and by Fujiwara, Ikeda and
Wakasugi [5] for the blow-up part. The sharp estimates of the lifespan are
also obtained by [5] except for the upper bound in the critical case.

Now, let us turn back to our problem (1.1). Wakasugi [18] has obtained
the blow-up result if $1 < p \leq p_F(n)$ and $\mu > 1$, or $1 < p \leq 1 + 2/(n + \mu - 1)$
and $0 < \mu \leq 1$. He has also shown in [17] that an upper bound of the lifespan
is
\[
\begin{cases}
C\varepsilon^{-(p-1)/(2-n(p-1))} & \text{if } 1 < p < p_F(n) \text{ and } \mu \geq 1, \\
C\varepsilon^{-(p-1)/(2-(n+\mu-1)(p-1))} & \text{if } 1 < p < 1 + \frac{2}{n + \mu - 1} \text{ and } 0 < \mu < 1,
\end{cases}
\]
where $C$ is a positive constant independent of $\varepsilon$. We note that the both
proofs in [17] and [18] are based on the so-called “test function method”
introduced by Zhang [24]. On the other hand, D’Abbicco [1] has obtained
the global existence result if $p > p_F(n)$, but $\mu$ has to satisfy
\[
\mu \geq \begin{cases} 
5/3 & \text{for } n = 1, \\
3 & \text{for } n = 2, \\
n + 2 & \text{for } n \geq 3 \text{ (and } p \leq 1 + 2/(n - 2)).
\end{cases}
\]
It is remarkable that, by the so-called Liouville transform;
\[
w(x, t) := (1 + t)^{\mu/2}u(x, t),
\]
(1.1) can be rewritten as
\[
\begin{cases}
w_{tt} - \Delta w + \frac{\mu(2 - \mu)}{4(1 + t)^2}w = \frac{|w|^p}{(1 + t)^{(p-1)/2}} & \text{in } \mathbb{R}^n \times [0, \infty), \\
w(x, 0) = \varepsilon f(x), \ w_t(x, 0) = \varepsilon \{((\mu/2)f(x) + g(x))}, & x \in \mathbb{R}^n.
\end{cases}
\tag{1.5}
\]
When $\mu = 2$, D’Abbicco, Lucente and Reissig [3] have obtained the following
result. Let
\[
p_\gamma(n) := \max \{p_F(n), \ p_0(n + 2)\},
\tag{1.6}
\]
where
\[
p_0(n) := \frac{n + 1 + \sqrt{n^2 + 10n - 7}}{2(n - 1)} \quad (n \geq 2)
\tag{1.7}
\]
is the so-called Strauss exponent, the positive root of the quadratic equation,
\[
\gamma(p, n) := 2 + (n + 1)p - (n - 1)p^2 = 0.
\tag{1.8}
\]
We note that $p_0(n)$ is the critical exponent for semilinear wave equations,
$\mu = 0$ in (1.1). They have shown in [3] that the problem (1.1) admits a
global-in-time solution in the classical sense for “small” $\varepsilon$ if $p > p_c(n)$ in the case of $n = 2, 3$ although the radial symmetry is assumed in $n = 3$, and that the classical solution of (1.1) with positive data blows-up in finite time if $1 < p \leq p_c(n)$ and $n \geq 1$. In the same year, with radial symmetric assumption, D’Abbicco and Lucente [4] extended the global existence result for $p_0(n + 2) < p < 1 + 2/(\max\{2, (n - 3)/2\})$ to odd higher dimensions $(n \geq 5)$. We remark that, in the case of $n = 1$, Wakasa [16] has studied the estimates of the lifespan and has shown that the critical exponent $p_c(1) = p_F(1) = 3$ changes to $p_0(1 + 2) = 1 + \sqrt{2}$ when the nonlinearity is a sign-changing type, $|u|^{p-1}u$, and the initial data is of odd functions. Both results in [3] and [16] heavily rely on the special structure of the massless wave equations, $\mu = 2$ in (1.5). In view of them, $\mu = 2$ may be an exceptional case. Recalling Wirth’ classification in the linear problem, (1.2), one may regard $\mu = 1$ as a threshold also for the semilinear problem, (1.1). In this sense, the blow-up result in Wakasugi [18] says that the solution may be “heat-like” if $\mu > 1$. Here, “heat-like” means that the critical exponent for (1.1) is Fujita exponent.

In this paper, we claim that the solution of (1.1) is “wave-like” in some case even for $\mu > 1$. Here, “wave-like” means that the critical exponent for (1.1) is bigger than Fujita exponent and is related to Strauss exponent. We also conjecture that such a threshold of $\mu$ depends on the space dimension $n$. The main tool of our result is Kato’s lemma in Kato [8] on ordinary differential inequalities which is improved to be applied to semilinear wave equations by Takamura [14]. Together with Yordanov and Zhang’s estimate in [23], we can prove a new blow-up result for wave-like solutions by means of some special transform for the time-derivative of the spatial integral of unknown functions.

This paper is organized as follows. In the next section, we state our main result. In the section 3, we estimate the spatial integral of unknown functions from below. Making use of such an estimate, we prove the main result for $\mu \geq 2$ in section 4, and for $0 < \mu < 2$ in section 5.

2 Main Result

First we define an energy solution of (1.1).

**Definition 2.1** We say that $u$ is an energy solution of (1.1) on $[0, T)$ if

$$u \in C([0, T), H^1(\mathbb{R}^n)) \cap C^1([0, T), L^2(\mathbb{R}^n)) \cap L^p_{loc}(\mathbb{R}^n \times [0, T))$$

(2.1)
satisfies
\[
\int_{\mathbb{R}^n} u_t(x,t)\phi(x,t)dx - \int_{\mathbb{R}^n} u_t(x,0)\phi(x,0)dx \\
+ \int_0^t ds \int_{\mathbb{R}^n} \left\{ -u_t(x,s)\phi_t(x,s) + \nabla u(x,s) \cdot \nabla \phi(x,s) \right\} dx \\
+ \int_0^t ds \int_{\mathbb{R}^n} \frac{\mu u_t(x,s)}{1+s} \phi(x,s)dx = \int_0^t ds \int_{\mathbb{R}^n} |u(x,s)|^p \phi(x,s)dx
\]
(2.2)
with any \( \phi \in C_0^\infty(\mathbb{R}^n \times [0,T]) \) and any \( t \in [0,T) \).

We note that, employing the integration by parts in (2.2) and letting \( t \to T \), we have that
\[
\int_{\mathbb{R}^n \times [0,T]} u(x,s) \left\{ \phi_{tt}(x,s) - \Delta \phi(x,s) - \left( \frac{\mu \phi(x,s)}{1+s} \right)_s \right\} dx ds
= \int_{\mathbb{R}^n} u(x,0)\phi(x,0)dx \\
- \int_{\mathbb{R}^n} u_t(x,0)\phi(x,0)dx \\
+ \int_{\mathbb{R}^n} \int_0^t ds \int_{\mathbb{R}^n \times [0,T]} |u(x,s)|^p \phi(x,s)dx ds.
\]
This is exactly the definition of a weak solution of (1.1).

Our main result is the following theorem.

**Theorem 2.1** Let \( n \geq 2 \),
\[0 < \mu < \mu_0(n) := \frac{n^2 + n + 2}{2(n + 2)} \quad \text{and} \quad p_F(n) \leq p < p_0(n + 2\mu),\] (2.3)
Assume that both \( f \in H^1(\mathbb{R}^n) \) and \( g \in L^2(\mathbb{R}^n) \) are non-negative and do not vanish identically. Suppose that an energy solution \( u \) of (1.1) satisfies
\[
\text{supp } u \subset \{(x,t) \in \mathbb{R}^n \times [0,T) : |x| \leq t + R\}
\] (2.4)
with some \( R \geq 1 \). Then, there exists a constant \( \varepsilon_0 = \varepsilon_0(f,g,n,p,\mu,R) > 0 \) such that \( T \) has to satisfy
\[
T \leq C\varepsilon^{-2(p-1)/\gamma(p,n+2\mu)}
\] (2.5)
for \( 0 < \varepsilon \leq \varepsilon_0 \), where \( C \) is a positive constant independent of \( \varepsilon \).

**Remark 2.1** Theorem 2.1 can be established also for \( n = 1 \) if one define \( \phi_1(x) = e^x + e^{-x} \) for \( x \in \mathbb{R} \) in Section 3 below. But the result is not new. See the following two remarks.
Remark 2.2 In view of (1.4) and (1.8), one can see that
\[ \gamma(p_F(n), n + 2\mu) = \frac{2}{n^2} \left\{ n^2 + n + 2 - 2(n + 2)\mu \right\}. \]
Therefore 0 < \mu < \mu_0(n) is equivalent to
\[ p_F(n) < p_0(n + 2\mu). \]
We note that \mu_0(2) = 1. This means that Theorem 2.1 just covers the non-effective range of \mu for n = 2. Since \mu_0(n) is increasing in n, Theorem 2.1 gives us the blow-up result on super-Fujita exponent even for \mu in outside of the non-effective range for n ≥ 3. We also note that \mu_0(n) < 2 for n = 2, 3, 4 and \mu_0(n) > 2 for n ≥ 5.

Remark 2.3 One can see also that
\[ \gamma \left( 1 + \frac{2}{n + \mu - 1}, n + 2\mu \right) = \frac{2 \left\{ (n - 1)^2 + (n - 3)\mu \right\}}{(n + \mu - 1)^2}. \]
Therefore we have that
\[ 1 + \frac{2}{n + \mu - 1} < p_0(n + 2\mu) \]
for n = 2 and 0 < \mu < 1, or n ≥ 3 and \mu > 0. This means that Theorem 2.1 includes the blow-up result in Wakasugi [18].

Remark 2.4 If \beta is in the scattering range, (1, \infty), for the problem,
\[ u_{tt} - \Delta u + \frac{\mu}{(1 + t)^2} u_t = |u|^p, \]
the result will be
\[ T \leq C e^{-2p(p-1)/\gamma(p,n)} \] for 1 < p < p_0(n)
for all \mu > 0. This estimate coincides with the one for non-damped equation,
\[ u_{tt} - \Delta u = |u|^p \]
except for the case of \( \int_{\mathbb{R}^n} g(x)dx \neq 0 \) in n = 2 and 1 < p ≤ 2. See Introduction of Takamura [14] for its summary. The proof of this fact will appear in our forthcoming paper.
3 Lower bound of the functional

Let \( u \) be an energy solution of (1.1) on \([0, T)\). We estimate

\[
F_0(t) := \int_{\mathbb{R}^n} u(x, t) dx
\]

from below in this section. Choosing the test function \( \phi = \phi(x, s) \) in (2.2) to satisfy \( \phi \equiv 1 \) in \( \{(x, s) \in \mathbb{R}^n \times [0, t] : |x| \leq s + R\} \), we get

\[
\int_{\mathbb{R}^n} u_t(x, t) dx - \int_{\mathbb{R}^n} u_t(x, 0) dx + \int_0^t ds \int_{\mathbb{R}^n} \frac{\mu u(x, s)}{1 + s} dx = \int_0^t ds \int_{\mathbb{R}^n} |u(x, s)|^p dx,
\]

which means that

\[
F'_0(t) - F'_0(0) + \int_0^t \frac{\mu F'_0(s)}{1 + s} ds = \int_0^t ds \int_{\mathbb{R}^n} |u(x, s)|^p dx.
\]

All the quantities in this equation except for \( F'_0(t) \) are differentiable in \( t \), so that so is \( F''_0(t) \). Hence we have

\[
F''_0(t) + \frac{\mu F'_0(t)}{1 + t} = \int_{\mathbb{R}^n} |u(x, t)|^p dx. \tag{3.1}
\]

Integrating this equation with a multiplication by \((1 + t)^\mu\), we obtain

\[
(1 + t)^\mu F'_0(t) - F'_0(0) = \int_0^t (1 + s)^\mu ds \int_{\mathbb{R}^n} |u(x, s)|^p dx. \tag{3.2}
\]

It follows from this equation and the assumption on the initial data that

\[
F'_0(t) \geq (1 + t)^{-\mu} F'_0(0) > 0 \quad \text{and} \quad F_0(t) \geq F_0(0) > 0 \quad \text{for} \quad t \geq 0. \tag{3.3}
\]

From now on, we employ the modified argument of Yordanov and Zhang [23]. Let us define

\[
F_1(t) := \int_{\mathbb{R}^n} u(x, t) \psi_1(x, t) dx,
\]

where

\[
\psi_1(x, t) := \phi_1(x) e^{-t}, \quad \phi_1(x) := \int_{S^{n-1}} e^{x \cdot \omega} dS_\omega.
\]

In view of (3.2) and the argument of (2.4)-(2.5) in [23], we know that there is a positive constant \( C_1 = C_1(n, p, R) \) such that

\[
(1 + t)^\mu F'_0(t) - F'_0(0) \geq C_1 \int_0^t (1 + s)^{\mu + (n-1)(1-p/2)} |F_1(s)|^p ds. \tag{3.4}
\]
In order to get a lower bound of $F_1(t)$, we turn back to (2.2) and obtain that

$$
\frac{d}{dt} \int_{\mathbb{R}^n} u_t(x,t) \phi(x,t) dx
+ \int_{\mathbb{R}^n} \left\{ -u_t(x,t) \phi_t(x,t) - u(x,t) \Delta \phi(x,t) \right\} dx
+ \int_{\mathbb{R}^n} \frac{\mu u_t(x,t)}{1 + t} \phi(x,t) dx = \int_{\mathbb{R}^n} |u(x,t)|^p \phi(x,t) dx.
$$

Multiplying the above equality by $(1 + t)^\mu$, we have that

$$
\frac{d}{dt} \left\{ (1 + t)^\mu \int_{\mathbb{R}^n} u_t(x,t) \phi(x,t) dx \right\}
+ (1 + t)^\mu \int_{\mathbb{R}^n} \left\{ -u_t(x,t) \phi_t(x,t) - u(x,t) \Delta \phi(x,t) \right\} dx
= (1 + t)^\mu \int_{\mathbb{R}^n} |u(x,t)|^p \phi(x,t) dx.
$$

Integrating this equality over $[0,t]$, we get

$$
(1 + t)^\mu \int_{\mathbb{R}^n} u_t(x,t) \phi(x,t) dx - \varepsilon \int_{\mathbb{R}^n} g(x) \phi(x,0) dx
- \int_0^t ds \int_{\mathbb{R}^n} (1 + s)^\mu u_t(x,s) \phi_t(x,s) dx
= \int_0^t ds \int_{\mathbb{R}^n} \left\{ (1 + s)^\mu u(x,s) \Delta \phi(x,s) + (1 + s)^\mu |u(x,s)|^p \phi(x,s) \right\} dx.
$$

It follows from this equation and

$$
\int_0^t ds \int_{\mathbb{R}^n} (1 + s)^\mu u_t(x,s) \phi_t(x,s) dx
= (1 + t)^\mu \int_{\mathbb{R}^n} u(x,t) \phi_t(x,t) dx - \int_{\mathbb{R}^n} u(x,0) \phi_t(x,0) dx
- \int_0^t ds \int_{\mathbb{R}^n} \mu (1 + s)^{\mu - 1} u(x,s) \phi_t(x,s) dx
- \int_0^t ds \int_{\mathbb{R}^n} (1 + s)^\mu u(x,s) \phi_{tt}(x,s) dx,
$$

9
which follows from integration by parts that

\[
(1 + t)^\mu \int_{\mathbb{R}^n} \{ u_t(x, t)\phi(x, t) - u(x, t)\phi_t(x, t) \} \, dx
- \varepsilon \int_{\mathbb{R}^n} g(x)\phi(x, 0) \, dx + \varepsilon \int_{\mathbb{R}^n} f(x)\phi_t(x, 0) \, dx
+ \int_0^t \int_{\mathbb{R}^n} \mu(1 + s)^{\mu-1} u(x, s)\phi_t(x, s) \, dx
= \int_0^t \int_{\mathbb{R}^n} (1 + s)^\mu u(x, s)\{\Delta \phi(x, s) - \phi_t(x, s)\} \, dx
+ \int_0^t \int_{\mathbb{R}^n} (1 + s)^\mu |u(x, s)|^p \phi(x, s) \, dx.
\]

If we put
\[
\phi(x, t) = \psi_1(x, t) = e^{-t} \phi_1(x) \quad \text{on supp } u,
\]
we have
\[
\phi_t = -\phi, \quad \phi_{tt} = \Delta \phi \quad \text{on supp } u.
\]
Hence we obtain that
\[
(1 + t)^\mu F_1'(t) + 2(1 + t)^\mu F_1(t) - \varepsilon \int_{\mathbb{R}^n} \{ f(x) + g(x) \} \phi(x) \, dx
= \int_0^t \mu(1 + s)^{\mu-1} F_1(s) \, ds + \int_0^t \int_{\mathbb{R}^n} (1 + s)^\mu |u(x, s)|^p \phi(t, x) \, dx,
\]
which yields
\[
F_1'(t) + 2F_1(t) \geq \frac{C_{f,g}\varepsilon}{(1 + t)^\mu} + \frac{1}{(1 + t)^\mu} \int_0^t \mu(1 + s)^{\mu-1} F_1(s) \, ds,
\]
where
\[
C_{f,g} := \int_{\mathbb{R}^n} \{ f(x) + g(x) \} \phi_1(x) \, dx > 0.
\]
Integrating this inequality over \([0, t]\) with a multiplication by \(e^{2t}\), we get
\[
e^{2t} F_1(t) \geq F_1(0) + C_{f,g}\varepsilon \int_0^t \frac{e^{2s}}{(1 + s)^\mu} \, ds
+ \int_0^t \frac{e^{2s}}{(1 + s)^\mu} \int_s^t \mu(1 + r)^{\mu-1} F_1(r) \, dr. \tag{3.5}
\]
We note that the assumption on \(f\) implies \(F_1(0) > 0\). Hence we find that there is no zero point of \(F_1(t)\) for \(t > 0\). Because the continuity of \(F_1\) implies
\( F_1(t) > 0 \) for small \( t > 0 \). If one assumes that there is a nearest zero point \( t_0 \) of \( F_1 \) to 0, then one has a contradiction in (3.5):

\[
e^{2t_0} F_1(t_0) = 0 \geq F_1(0) + C_{f,g} \varepsilon \int_0^{t_0} \frac{e^{2s}}{(1 + s)^\mu} ds + \int_0^{t_0} \frac{e^{2s}}{(1 + s)^\mu} ds \int_0^s \mu(1 + r)^{\mu-1} F_1(r) dr.
\]

The last term in the right-hand side of this inequality is positive by \( F_1(t) > 0 \) for \( 0 < t < t_0 \). Turning back to (3.5), we obtain

\[
F_1(t) > \frac{C_{f,g}}{2(1 + t)^\mu}(1 - e^{-2t}) + e^{-2t} F_1(0) \geq \frac{C_{f,0} \varepsilon}{2(1 + t)^\mu} \quad \text{for } t \geq 0.
\]

Here we have used the fact that \( C_{f,g} > C_{f,0} \).

Plugging this estimate into (3.4), we have

\[
(1 + t)^\mu F_0'(t) - F_0'(0) > \frac{C_1 C_{f,0}^p}{2^p} \varepsilon^p \int_0^t (1 + s)^{\mu(1-p)+(n-1)(1-p/2)} ds.
\]

Since \( F_0'(0) > 0 \) and it follows from \( t \geq 1 \) that

\[
\int_0^t (1 + s)^{\mu(1-p)+(n-1)(1-p/2)} ds \geq (2t)^{\mu(1-p)} \int_0^{t/2} s^{(n-1)(1-p/2)} ds \\
\geq 2^{\mu(1-p)-(n-1)(1-p/2)+1} t^{1+\mu(1-p)+(n-1)(1-p/2)},
\]

we obtain that

\[
F_0'(t) > C_2 \varepsilon^p t^{1-p+p(n-1)(1-p/2)} \quad \text{for } t \geq 1,
\]

where

\[
C_2 := \frac{C_1 C_{f,0}^p}{2(\mu+1)p+(n-1)(1-p/2)-1} > 0.
\]

Here we have used the fact that

\[
1 + (n - 1) \left(1 - \frac{p}{2}\right) > 0
\]

follows from

\[
p < p_0(n + 2\mu) < \begin{cases} p_0(n) \leq p_0(4) = 2 & \text{for } n \geq 4, \\
p_0(3) = 1 + \sqrt{2} < 3 & \text{for } n = 3, \\
p_0(2) = (3 + \sqrt{17})/2 < 4 & \text{for } n = 2.
\end{cases}
\]
Integrating this inequality over \([1, t]\) and making use of \(F_0(0) > 0\) and
\[
\int_1^t s^{1-p+(n-1)(1-p/2)} ds \geq t^{-\mu p} \int_{t/2}^t s^{1+(n-1)(1-p/2)} ds \quad \text{for } t \geq 2,
\]
we get
\[
F_0(t) > C_3 \varepsilon t^{2-p+(n-1)(1-p/2)} \quad \text{for } t \geq 2,
\]
where
\[
C_3 := \frac{C_2}{2^{2+(n-1)(1-p/2)}} > 0.
\]

4 Proof of Theorem 2.1 for \(\mu \geq 2\)

Let us define
\[
F(t) := \int_{\mathbb{R}^n} w(x, t) dx = (1 + t)^{\mu/2} F_0(t),
\]
where \(w\) is the solution of (1.5). We note that (3.1) yields
\[
F''(t) + \frac{\mu(2 - \mu)}{4(1 + t)^2} F(t) = (1 + t)^{-\mu(p-1)/2} \int_{\mathbb{R}^n} |w(x, t)|^p dx. \tag{4.1}
\]
Then it follows from (2.4) and Hölder's inequality that
\[
\int_{\mathbb{R}^n} |w(x, t)|^p dx \geq \{\text{vol}(B^n(0, 1))\}^{1-p}(t + R)^{-n(p-1)} |F(t)|^p. \tag{4.2}
\]
By combining (4.1) and (4.2), and noting the assumption \(R \geq 1\), we come to
\[
F''(t) + \frac{\mu(2 - \mu)}{4(1 + t)^2} F(t) \geq C_4 (1 + t)^{-\frac{p}{2}(p-1)-n} |F(t)|^p \quad \text{for } t \geq 0, \tag{4.3}
\]
where
\[
C_4 := \{\text{vol}(B^n(0, 1))\}^{1-p} R^{-n(p-1)} > 0.
\]
Due to (3.3), we have that
\[
F(t) = (1 + t)^{\mu/2} F_0(t) > 0,
F'(t) = \frac{\mu}{2} (1 + t)^{\mu/2-1} F_0(t) + (1 + t)^{\mu/2} F_0'(t) > 0,
\]
which implies that
\[
F(0) = F_0(0) = \|f\|_{L^1(\mathbb{R}^n)} \varepsilon,
F'(0) = \frac{\mu}{2} F_0(0) + F_0'(0) = \left(\frac{\mu}{2} \|f\|_{L^1(\mathbb{R}^n)} + \|g\|_{L^1(\mathbb{R}^n)}\right) \varepsilon. \tag{4.5}
\]

\[12\]
From now on, we focus on the case of \( \mu \geq 2 \). Then it follows from (4.3) and (4.4) that
\[
F''(t) \geq C_4 (1 + t)^{-\left(n + \mu / 2\right)(p - 1)} |F(t)|^p.
\] (4.6)

We shall employ the following lemma now.

**Lemma 4.1 (Takamura[14])** Let \( p > 1, a > 0, q > 0 \) satisfy
\[
M := p - 1 - a - q + 1 > 0.
\] (4.7)

Assume that \( F \in C^2([0,T]) \) satisfies
\[
\begin{align*}
F(t) &\geq A t^a &\text{for } t \geq T_0, \\
F''(t) &\geq B (t + R)^{-q} |F(t)|^p &\text{for } t \geq 0, \\
F(0) &\geq 0, \ F'(0) > 0,
\end{align*}
\] (4.8) (4.9) (4.10)

where \( A, B, R, T_0 \) are positive constants. Then, there exists a positive constant \( C_0 = C_0(p,a,q,B) \) such that
\[
T < 2^{2/M} T_1
\] (4.11)
holds provided
\[
T_1 := \max \left\{ T_0, \frac{F(0)}{F'(0)}, R \right\} \geq C_0 A^{-(p-1)/(2M)}. \] (4.12)

Due to the lower bound of \( F_0 \) in (3.6) and the definition of \( F(t) \) in (4.4), we have
\[
F(t) > C_3 \varepsilon p t^{2-\mu p + (n-1)(1-p/2)+\mu/2} \quad \text{for } t \geq 2, \] (4.13)
which is (4.8) in Lemma 4.1 with
\[
A = C_3 \varepsilon^p, \quad a = 2 - \mu p + (n-1) \left( 1 - \frac{p}{2} \right) + \frac{\mu}{2}, \quad T_0 = 2.
\]
The inequality (4.9) with
\[
B = C_4, \quad q = \left( n + \frac{\mu}{2} \right) (p - 1)
\]
follows from (4.6), and (4.10) is already established by (4.5). The final step to use Lemma 4.1 is to check the sign of \( M \). By the assumption that \( p < p_0(n + 2\mu) \), we have
\[
M = \frac{\gamma(p,n+2\mu)}{4} > 0.
\]
Set

\[ T_0 = C_0 A^{-(p-1)/(2M)} = C_0 C_3^{2(p-1)/\gamma(p,n+2\mu)} \varepsilon^{-2p(p-1)/\gamma(p,n+2\mu)}. \]

Then, since \( F(0)/F'(0) \) is independent of \( \varepsilon \) by (4.5), one can see that there is an \( \varepsilon_0 = \varepsilon_0(f,g,n,p,\mu,R) > 0 \) such that

\[ T_0 \geq \max \left\{ \frac{2F(0)}{F'(0)} \right\} \quad \text{for } 0 < \varepsilon \leq \varepsilon_0. \]

This means that \( T_1 = T_0 \) in (4.12). Therefore the conclusion of Lemma 4.1 implies that the maximal existence time \( T \) of \( F(t) \) has to satisfy

\[ T \leq C_5 \varepsilon^{-2p(p-1)/\gamma(p,n+2\mu)} \quad \text{for } 0 < \varepsilon \leq \varepsilon_0, \]

where

\[ C_5 := 2^{8/\gamma(p,n+2\mu)} C_0 C_4^{2(p-1)/\gamma(p,n+2\mu)} > 0. \]

This completes the proof in the case of \( \mu \geq 2 \). \qed

5 Proof of Theorem 2.1 for \( 0 < \mu < 2 \)

Before showing the proof of Theorem 2.1 for \( 0 < \mu < 2 \), we first prepare the following lemma:

**Lemma 5.1** Suppose that the assumption in Theorem 2.1 is fulfilled. Then it holds that

\[ F'(t) > \sqrt{\frac{C_4}{2(p+1)}} (1+t)^{-\left(\frac{n+\mu}{2}\right)(p-1)/2} F(t)^{(p+1)/2} \quad (5.1) \]

for \( t \geq C_6 \varepsilon^{-2p(p-1)/\gamma(p,n+2\mu)} \), where we set

\[ C_6 := \left( \frac{\mu(2-\mu)(p+1)}{2C_3^{p-1} C_4} \right)^{1/X} > 0 \]

and

\[ X := 2 - \left( n + \frac{\mu}{2} \right) (p - 1) + (p - 1) \left\{ 2 - \mu p + (n - 1) \left( 1 - \frac{p}{2} \right) + \frac{\mu}{2} \right\} \]

\[ = \frac{\gamma(p,n+2\mu)}{2}. \]

\( C_3, C_4 \) are the one in (3.6), (4.3), respectively,
Proof. Multiplying the both sides of (4.3) by \((1 + t)^2F'(t) > 0\) and noting that (4.4), we get
\[
\frac{(1 + t)^2}{2} \left\{ (F'(t))^2 \right\}' + \frac{\mu(2 - \mu)}{8} \{ F(t)^2 \}' \geq C_4(1 + t)^2(1 - n - \mu/2)(p-1) F(t)^p F'(t)
\]
for \(t \geq 0\).

Integration by parts yields that
\[
\frac{(1 + t)^2}{2} (F'(t))^2 + \frac{\mu(2 - \mu)}{8} F(t)^2 \geq C_4 \int_0^t (1 + s)^2(1 - n - \mu/2)(p-1) F(s)^p F'(s) ds
\]
for \(t \geq 0\).

Noting the assumption on \(p\)
\[
p \geq p_F(n) > 1 + \frac{2}{n + \frac{\mu}{2}} \quad \text{for } \mu > 0,
\]
it is easy to get that
\[
2 - \left( n + \frac{\mu}{2} \right)(p - 1) < 0.
\]

And hence we have
\[
\int_0^t (1 + s)^2(1 - n - \mu/2)(p-1) F(s)^p F'(s) ds \geq (1 + t)^2(1 - n - \mu/2)(p-1) \frac{F(t)^{p+1} - F(0)^{p+1}}{p + 1}.
\]

Since
\[
p_F(n) = 1 + \frac{2}{n - \mu} > \frac{2}{n + 1 - \mu} \quad \text{for } n \geq 2 \text{ and } 0 < \mu < 2,
\]
and hence
\[
p > \frac{2}{n + 1 - \mu}.
\]

This is equivalent to
\[
p \left( 2 - \mu p + (n - 1) \left( 1 - \frac{p}{2} \right) + \frac{\mu}{2} \right) > \frac{\gamma(p, n + 2\mu)}{2}.
\]

Thus, for \(t \geq C_6 \varepsilon^{-2p(p-1)/\gamma(p, n + 2\mu)} \geq 2 \varepsilon \) (\(\varepsilon\) small enough), we have
\[
C_3 \varepsilon^p t^{2 - \mu p + (n - 1)(1 - p/2) + \mu/2} \geq 2 \| f \|_{L^1(R^n)} \varepsilon,
\]
(5.2)
which implies

\[ F(t) \geq 2F(0). \]  

(5.3)

Hence, it follows from

\[ F(t)^{p+1} - F(0)^{p+1} \geq F(t)^p \{ F(t) - F(0) \} \geq \frac{1}{2} F(t)^{p+1} \]

that

\[ \frac{(1 + t)^2}{2} (F'(t))^2 + \frac{\mu(2 - \mu)}{8} F(t)^2 > \frac{C_4(1 + t)^{2-(n+\mu/2)(p-1)} F(t)^{p+1}}{2(p + 1)} \]

(5.4)

for \( t \geq C_6 e^{-2p(p-1)/\gamma(p,n+2\mu)} \).

On the other hand, for \( t \geq C_6 e^{-2p(p-1)/\gamma(p,n+2\mu)} \), we have

\[ \frac{C_4}{4(p + 1)} (1 + t)^{2-(n+\mu/2)(p-1)} \{ C_3 e^{p^2 - \mu p + (n - 1)(1 - p/2) + \mu/2} \} t^{p-1} \geq \frac{\mu(2 - \mu)}{8} \]

which gives us

\[ \frac{C_4}{4(p + 1)} (1 + t)^{2-(n+\mu/2)(p-1)} F(t)^{p+1} \geq \frac{\mu(2 - \mu)}{8} F(t)^2 \]  

(5.5)

by combining (4.13). Therefore, we get (5.1) from (5.4).

\[ \blacksquare \]

By (5.1), it is easy to see that there is a \( \varepsilon_0 = \varepsilon_0(f, g, n, p, \mu, R) > 0 \) such that

\[ \frac{F''(t)}{F(t)^{1+\delta}} > \sqrt{\frac{C_4}{2(p + 1)} (1 + t)^{-(n+\mu/2)(p-1)/2} F(t)^{(p-1)/2 - \delta}} \]

with \( 0 < \delta < (p - 1)/2 \) holds for

\[ t \geq T_1 := C_6 e^{-2p(p-1)/\gamma(p,n+2\mu)} \text{ and } 0 < \varepsilon \leq \varepsilon_0. \]

Here we use our lower bound of \( F \) in (4.13) again to get

\[ \frac{F''(t)}{F(t)^{1+\delta}} > C_{F_3}^{(p-1)/2 - \delta} \sqrt[2(p + 1)]{C_4} e^{p\{(p-1)/2 - \delta\} t^Y} \text{ for } t \geq T_1, \]

(5.6)

where

\[ Y := \left( \frac{p - 1}{2} - \delta \right) \left[ 2 - \mu p + (n - 1) \left( 1 - \frac{p}{2} \right) + \frac{\mu}{2} \right] - \left( n + \frac{\mu}{2} \right) \frac{p - 1}{2} \]

\[ = \gamma(p,n+2\mu) + \left( 2 - \mu p + (n - 1) \left( 1 - \frac{p}{2} \right) + \frac{\mu}{2} \right) \delta. \]
Therefore, taking $\delta$ small enough such that $Y + 1 > 0$, we then have by integrating (5.6) over $[T_1, t]$,

$$\frac{F(T_1) - \delta}{\delta} > \frac{C_3(p-1)/2-\delta}{Y + 1} \sqrt{\frac{C_4}{2(p + 1)}} \varepsilon^{p((p-1)/2-\delta)}(t^{Y+1} - T_1^{Y+1}) \quad \text{for } t \geq T_1.$$ 

Making use of (4.13) with $t = T_1$ in this inequality, we obtain that

$$1 > C_7 \varepsilon^{p(p-1)/2}T_1^{\gamma(p,n+2\mu)/4-(Y+1)}(t^{Y+1} - T_1^{Y+1}) \quad \text{for } t \geq T_1,$$

where

$$C_7 := \frac{\delta C_3^{(p-1)/2}}{Y + 1} \sqrt{\frac{C_4}{2(p + 1)}} > 0.$$

If one sets $t = kT_1$ with $k > 1$, then, due to the definition of $T_1$, one has

$$1 > C_7 C_6^{\gamma(p,n+2\mu)/4}(k^{Y+1} - 1).$$

Therefore the conclusion of the Theorem 2.1,

$$T \leq C_8 \varepsilon^{-2p(p-1)/\gamma(p,n+2\mu)} \quad \text{for } 0 < \varepsilon \leq \varepsilon_0,$$

is now established, where

$$C_8 := \left(1 + C_7^{-1} C_6^{-\gamma(p,n+2\mu)/4}\right)^{1/(Y+1)} C_6 > 0.$$

This completes the proof in the case of $0 < \mu < 2$. \qed
