Abstract: Mexico is one of the three areas of the world with the greatest terrestrial and cultural biological diversity. The diversity of Mexican medicinal flora has been studied for a long time and several bioactive compounds have been isolated. The investigation of marine resources, and particularly the potential of Mexican marine resources, has not been intensively investigated, even though the Yucatan Peninsula occupies 17.4% of the total of the Mexican coast, with great biological diversity in its coasts and the ocean. There are very few studies on the chemistry of natural products from marine organisms that were collected along the coasts of the Yucatan Peninsula and most of them are limited to the evaluation of the biological activity of their organic extracts. The investigations carried out on marine species from the Yucatan Peninsula resulted in the identification of a wide structural variety of natural products that include polyketides, terpenoids, nitrogen compounds, and biopolymers with cytotoxic, antibacterial, antifouling, and neurotoxic activities. This review describes the literature of bioprospecting and the exploration of the natural product diversity of marine organisms from the coasts of the Yucatan Peninsula up to mid-2019.

Keywords: natural products; Yucatan peninsula; marine biodiversity

1. Introduction

The potential of marine natural products in drug discovery is invaluable due to the extremely rich biodiversity of the marine environment. The marine environment contains a large number of species which are the source of a wide range of structurally diverse bioactive secondary metabolites. Approximately 29,000 marine natural products are known, from which eight compounds have become commercialized drugs. During the last decade, more than 1000 new marine natural products have been annually isolated, but the set of new and unique structures is far from being exhausted [1,2]. The interest in marine organisms has been increasing, since they are capable of producing a great diversity of novel metabolites, such as unusual nucleosides, bioactive terpenes, sterols, cyclic peptides, alkaloids, fatty acids, peroxides, and amino acid derivatives, many of them with high potential for pharmacological applications [3].

The Yucatan Peninsula in Mexico, which comprises the Mexican states of Campeche, Quintana Roo, and Yucatan, is known as a biotic province [4]. Although marine organisms constitute a recognized source of a wide range of structurally diverse natural products, research that is focused on marine natural products from the Yucatan Peninsula is still in infancy, mainly when compared to the numerous studies of those isolated from terrestrial organisms, especially from plants [5].
On the other hand, a priority task for the conservation and management of coastal areas, such as the Yucatan Peninsula, and for the discovery of new sources of novel natural products, is the study of their biodiversity. The first effort aimed at determining the state of health of the coast of the Yucatan Peninsula was reported in 2010. Pech-Pool and Ardisson Herrera described the identification of more than 400 thousand organisms from marine and coastal environments and lagoons, belonging to 529 species, which were distributed in 13 phyla, 26 classes, 28 orders, 113 families, and 358 genera. Of the registered species, 45% (237) corresponded to the Arthropod (Crustacea); 22% (118) to Mollusca; 14% (72) to the Nematoda; and, 13% (68) to the Annelida phyla. The remaining 6% (33) belonged to the Echinoderms, Nemertea, Platynereisida, Sipuncula, Polychaeta, Chordata, and Cnidaria phyla [6]. More specifically, taxonomic identification of coral and sponges was also described. Thus, from a total of 31 registered coral species, 15 corresponded to order Scleractinia, being Poritidae and Favidae the most important families that were represented by four species each; other 15 species were octocorals, seven of them belonged to Plexauridae family and, finally, the remaining species was a hydrocoral [7]. On the other hand, most of the registered sponges belonged to three classes: Calcarea, Hexactinellida and Demospongiae, the last being the most predominant and with the greatest diversity. The 50 species registered were distributed in 10 orders, two subclasses, 25 families, and 35 genera [8]. The results of studies that were focused on marine biodiversity in specific benthic communities were also reported. For example, the biodiversity analysis of the Alacranes Reef, one of the largest platform-type reefs in Mexico, covering an approximate area of 333.7 km², showed that this benthic community mainly consists of macroalgae (50.1%), seagrass (16.2%), algal mat (13.6%), scleractinia corals (11.1%), octocorals (7.6%), sponges (0.6%), and other vagile and sessile organisms (0.5%) and hydrocorals (0.3%) [9]. A very recent report published in 2019 describes 31 ascidian species from the Yucatan Peninsula that were grouped into 13 families and 19 genera, being two species, Clavelina sp. and Pyura sp., described for the first time [10].

With the present review, we will cover the current knowledge of bioprospecting and the exploration of the natural product diversity of marine organisms that were collected along the coasts of the Yucatan Peninsula up to mid-2019.

2. Marine Natural Products from the Yucatan Peninsula

Although the number of secondary metabolites that were isolated from marine organisms collected along the coasts of the Yucatan Peninsula is not very high, they display a great diversity of structures and biological activities. They can be grouped into the following categories as polyketides (aliphatic polyketides, glycolipids, and aromatic acids), terpenoids (diterpenes and sesterterpenes, steroids, and triterpenoids saponins), nitrogen compounds (indole derivatives, nucleosides, nitrogenous bases, and conotoxins), and biopolymers, based upon the putative biogenetic origins.

The following sections show a detailed list of the isolated natural products from the reported species, along with their biological activities, as well as the taxonomic identification of marine organisms from which they were obtained.

2.1. Polyketides

2.1.1. Aliphatic Polyketides

The interest on the study of fatty acids derivatives from marine organisms, specifically ω-3 polyunsaturated fatty acids, was sparked by the approval of Lovaza® by the FDA as a mixture of ethyl esters of eicosapentaenoic acid and docosahexaenoic acid used as therapeutic agent for reducing serum triglycerides [1]. The Italian researcher group led by Cimino from Naples published in 1999 the isolation and structure elucidation of three new fatty acids derivatives, the butenolide lipids 1–3 from the gorgonian Pterogorgia anceps, which were collected at Puerto Morelos, Quintana Roo state. The new fatty acids derivatives were identified as (R)-3-hexadecyl-5-methylfuran-2(5H)-one (1), (R)-3-(14-((3S,4R,5R)-4-hydroxy-5-methyl-2-oxotetrahydrofuran-3-yl)tetradecyl)-5-methylfuran-2(5H)
-one (2), and (R)-4-hydroxy-5-methyl-3-(14-((R)-5-methyl-2-oxo-2,5-dihydrofuran-3-yl)tetradecyl)furan-2(5H)-one (3). The proposed stereochemistry was confirmed by acetylation of 2 and 3 to give the acetate derivatives 4 and 5, respectively [11]. Palmitic acid (6) was also isolated from the sponge Haliclona tubifera (now H. (Reniera) tubifera) that was collected on the coasts of the Yucatan state [12] (Figure 1).

![Figure 1. Structures of the aliphatic polyketides 1–3, along with their synthetic acetate derivatives 4 and 5, isolated from the gorgonian Pterogorgia anceps and palmitic acid (6) isolated from the sponge Haliclona tubifera (now H. (Reniera) tubifera).](image)

2.1.2. Glycolipids

Marine glycolipids are amphiphilic compounds that are divided into two main groups: glycosylglycerolipids (GGls) and glycosphingolipids (GSLs). Glycoglycerolipids are composed by a glycerol unit glycosylated at one primary alcoholic function. Sulfoquinovosyldiacylglycerols constitute one of the most common types of glycoglycerolipids (GGls) found in marine organisms and some of them are present in large amounts in photosynthetic membranes of cyanobacteria, algae and higher plants. Antiviral activity against HIV-1 was reported for some sulfoquinovosyldiacylglycerols that were isolated from cyanobacteria [13]. Freile–Pelegrin and collaborators reported in 2010, from the brown algae Lobophora variegata, collected at Puerto Morelos in Quintana Roo state, the isolation, and structure elucidation of a new glycoglycerolipid, 1-O-palmitoyl-2-O-oleoyl-3-O-(6′′′-sulfo-α-D-quinovopyranosyl)-glycerol (7), along with two known glycolipids: 1-O-palmitoyl-2-O-myristoyl-3-O-(6′′′-sulfo-α-D-quinovopyranosyl)-glycerol (8), and 1,2-di-O-palmitoyl-3-O-(6′′′-sulfo-α-D-quinovopyranosyl)-glycerol (9). The mixture of the three sulfoquinovosyldiacylglycerols 7–9 showed high in vitro antiprotozoal activity against Entamoeba histolytica (IC50 value of 3.9 μg mL⁻¹) and moderate activity against Trichomonas vaginalis trophozoites (IC50 value 8.0 μg mL⁻¹), with good selective index (SI > 10). However, they were less effective than metronidazole being used as control (IC50 = 0.13 and 0.04 μg mL⁻¹/0.759 and 0.230 nM, respectively) [14]. The relative configuration of the glycerol unit in 7–9 was not specified (Figure 2).

![Figure 2. Structures of marine glycolipids isolated from the brown algae Lobophora variegata.](image)
2.1.3. Aromatic Acids

Several aromatic acids, such as p-hydroxybenzaldehyde (10), vanillin (11), benzoic acid (12), p-hydroxybenzoic acid (13), and phenylacetic acid (14), were isolated from the sponge Haliclona tubifera (now H. (Reniera) tubifera) [12] (Figure 3).

![Figure 3. Structures of aromatic acids isolated from the sponge Haliclona tubifera (now H. (Reniera) tubifera).](image)

2.2. Terpenoids

2.2.1. Diterpenes and Sesterterpenes

Terpenoid biogenesis is one of the dominant pathways of most marine natural products, mainly those that were isolated from cnidarians followed by sponges. The wide variety of biological activities that were found in marine terpenes, together with their ecological role in the marine environment, makes them a very interesting target of study apart from being potential drugs [15]. Pech-Puch et al. reported in 2019 the isolation and structural characterization of seven terpenoids from the sponge Spongia tubulifera (now S. (Spongia) tubulifera) that were collected at Rio Indio, Quintana Roo state. Two of them resulted in being new natural products, 3β-hydroxyspongia-13(16),14-dien-2-one (15) and 19-dehydroxy-spongian diterpene 17 (16), while the remaining five corresponded to previously reported terpenes, three spongia furanoditerpenes: 9-nor-3-hydroxyspongia-3,13(16),14-trien-2-one (17), 3β, 19 dihydroxyspongia-13(16),14-dien-2-one (epispongadiol) (18), and spongian diterpene 17 (19); the furanoditerpene ambliol C (20) and the sesterterpene scalarin (21). The pharmacological analysis of the isolated compounds displayed a very mild cytotoxic activity for 15, 18, and 20, while they showed no antimicrobial (Acinetobacter baumannii, Pseudomonas aeruginosa, Klebsiella pneumoniae, and Staphylococcus aureus) or antiviral (HAdV5 and HAdV5-GFP) activities [16] (Figure 4).

From the organic extracts of the brown seaweed Dictyota ciliolata, collected at the Caribbean coast of Quintana Roo state, Caamal-Fuentes et al. isolated the diterpenes pachydicytol A (22) and dictyol B acetate (23) in 2014. Cytotoxic and antiproliferative activities of the isolated compounds were evaluated on a panel of cancer cell lines (oral carcinoma (KB), epithelial carcinoma of the larynx (Hep-2), breast adenocarcinoma (MCF-7), and cervix adenocarcinoma (SiHa)) and a human cell embryonic kidney cell line HEK-293 as the control). Compound 22 exhibited inhibitory activity against all of the tested cancer cell lines, whereas diterpene 23 showed cytotoxic activity against epithelial carcinoma of the larynx-HEP-2 (CC50 = 19.6 µg mL−1/0.056 µM) and antiproliferative activity against breast-MCF-7 (IC50 = 38.3 µg mL−1/0.11 µM) and cervix-SiHa (IC50 = 34.4 µg mL−1/0.099 µM) [17] (Figure 4).
2.2. Steroids

High diversity unusual structures of steroid derivatives with multiple potential biological properties have been isolated from marine organisms. Bohlin et al. reported several marine steroids as acetates from the sponge Teichaxinella morchella (now Axinella corrugata) collected at a depth of 15 m at Puerto Morelos in Quintana Roo state in 1981. Two new sterols, (22E,24S)-3E-acetoxymethyl-24-methyl-27-nor-A-nor-5α-cholesterol-22-ene (A-nor-patinosterol) (24) and (22E,24R)-3E-acetoxymethyl-24-dimethyl-A-nor-5α-cholesterol-22-ene (A-nor-dinosterol) (25), along with six known sterols, (22E)-3E-acetoxymethyl-A-nor-5α-cholesterol-22-ene (26), 3β-acetoxymethyl-A-nor-5α-cholestanate (27), (22E,24S)-3E-acetoxymethyl-24-ethyl-A-nor-5α-cholesterol-22-ene (28), (22E,24R)-3E-acetoxymethyl-24-ethyl-A-nor-5α-cholesterol-22-ene (29), (22E,24S)-3E-acetoxymethyl-24-methyl-A-nor-5α-cholesterol-22-ene (30), and (22E,24R)-3E-acetoxymethyl-24-methyl-A-nor-5α-cholesterol-22-ene (31) were isolated. Furthermore, four known steroids were also detected, (24S)-3E-acetoxymethyl-24-methyl-A-nor-5α-cholestanate (32), (24R)-3E-acetoxymethyl-24-methyl-A-nor-5α-cholestanate (33), (24R)-3E-acetoxymethyl-24-ethyl-A-nor-5α-cholestanate (34), and (24S)-3E-acetoxymethyl-24-ethyl-A-nor-5α-cholestanate (35) [18]. The relative configuration at C-3 and C-20 of 24–35 was not specified (Figure 5), and no biological data were reported for these compounds.

From two brown algae, Padina sanctae-crucis and Turbinaria tricotostata, which were collected at the Caribbean coast of Quintana Roo state, were reported in 2014 from the isolation of fucosterol (36) and 24β-hydroperoxy-24-vinylcholesterol (37). Cytotoxic (CC50) and antiproliferative (IC50) activity assays on a panel of human cancer cell lines (KB, Hep-2, MCF-7, and SiHa) and a human cell embryonic kidney cell line HEK-293 as the control, showed that 36 is cytotoxic against Hep-2 and SiHa cell lines (CC50 of 14.8 and 18.6 µg mL−1; 0.036 and 0.045 µM, respectively), with a high selectivity index towards Hep-2 (SI = 10) and antiproliferative activity against MCF-7 and SiHa (IC50 of 43.3 and 34.0 µg/mL/0.10 and 0.083 µM, respectively). Fucosterol (36) was also isolated from the brown algae Dictyota ciliolata. Steroid 37 displayed not only the highest cytotoxic activity (CC50 of 3.1 µg mL−1/7.0 nM), but also a high selectivity index (SI = 16.2) on KB cell lines. Additionally, 37 exhibited a moderate cytotoxic activity towards the Hep-2, MCF-7, and SiHa cell lines (CC50 of 10.5, 12.1, and 18.9 µg mL−1/0.024, 0.027, and 0.042 µM, respectively) with a lower selectivity index (SI of 4.7, 4.1, and 12.6, respectively) [17] (Figure 5).
0.027, and 0.042 μM, respectively) with a lower selectivity index (SI of 4.7, 4.1, and 12.6, respectively) [17] (Figure 5).

Figure 5. Steroid structures of the A-nor-5α-cholestanes 24–35 isolated from the sponge Teichaxinella morchella (now Axinella corrugata) and the cholesterol derivatives 36 and 37 isolated from the brown algae Padina sanctae-crucis and Turbinaria tricostata.

2.2.3. Triterpenoid Saponins

Sea cucumbers constitute a rich source of triterpenoid saponins, with some of them exerting pharmacological effects [19]. From the sea cucumber Astichopus multifidus, collected on the Yucatan Peninsula coasts, Mena-Rejón and collaborators reported the isolation and the structural elucidation of three oligoglycoside triterpenes in 2016. Two of them, stichloroside B (38) and astichoposide C (39), were known, while the third one, named as astichoposide D (40), turned out to be a new natural product. Antiproliferative activity assays against two cancer lines, MCF-7 (ATCC HTB-22) and a highly invasive triple-negative breast cancer MDA-MB-231 (ATCC HTB-26), displayed that 38 had the highest antiproliferative activity against MCF-7 cells (6.45 μM), while 39 had the highest antiproliferative activity against the MDA-MB-231 cells (3.80 μM) [20]. The research group of Mena-Rejón also reported in 2013 the isolation of the known triterpenoid saponin holothurin B (41) from the sea cucumber Holothuria floridana (now H. (Halodeima) floridana) [21] (Figure 6).
Figure 6. Structures of the triterpenoid saponins isolated from the sea cucumbers: the hexaglycosides 38–40 from Astichopus multifidus and the diglycoside 41 from Holothuria floridana (now H. (Halodeima) floridana).

2.3. Nitrogen Compounds

2.3.1. Indole Derivatives

Olguin-Uribe et al. isolated two indoles, indole-3-carbaldehyde (42) and its brominated derivative, 6-bromoindole-3-carbaldehyde (43), in 1997 from two different sources, the tunicate Stomozoa murrayi (currently known as Stomozoa roseola) and the bacterium Acinetobacter sp. associated to its surface [22]. The tunicate was collected at a depth of 3–5 m in Puerto Morelos, Quintana Roo state, very close to the Institute of Marine Sciences and Limnology research station of the National Autonomous University of Mexico (UNAM). These compounds were evaluated in several biological assays. The brominated...
indole 43 displays antimicrobial activity by inhibiting the growth of four marine bacterial strains SM-S2, SM-Z, Bacillus marinus, and Vibrio campbellii, while its debrominated analog 42 shows no inhibitory activity. On the other hand, both of the compounds exhibit antifouling activity by completely inhibiting the settlement of Balanus amphitrite (now Amphibalanus amphitrite) at the highest concentration tested at 100 µg mL⁻¹ (0.13 and 0.084 µM respectively) and, even, the most active compound 43 can inhibit larval settlement by 80% at 10 µg mL⁻¹/0.044 µM. Finally, these compounds showed no antipredatory (deterrent) activity against the Serranus cabrilla fish, which were collected in the Mediterranean Sea, or significant antialgal activity against the diatom Nitzchia acicularis (Figure 7).

Figure 7. Structures of indole derivatives 42 and 43 from the tunicate Stomozoa murrayi (now Stomozoa roseola) and the bacterium Acinetobacter sp. and 44 from the mollusk Octopus maya.

Pech-Puch et al. reported the isolation of another indole, serotonin (44), from the salivary glands of Octopus maya collected in Sisal, Yucatan state in 2016 [23]. The neurotoxic activity previously found in its extract was attributed to that compound (Figure 7).

2.3.2. Nucleosides and Nitrogenous Bases

The importance of the study of nucleosides comes from the fact that the arabino-nucleosides spongorthymidine and spongouridine, isolated from a marine sponge, were the first marine natural products that showed their potential as drugs, because they constituted the basis of the development of the first synthetic nucleosides approved as therapeutic drugs: the anticancer cytarabine (ara-C) and the antiviral vidarabine (ara-A) [1].

Three nucleosides, thymidine (45), 2′-desoxyuridine (46), and uridine (47), were isolated from the sponge Halichondria magniconulosa (now H. (Halichondria) magniconulosa) collected at 0.5–1 m of depth in Chabihau, Yucatan state, and reported by the research group of Mena-Rejón in 2018 [24]. The same year, Medina-Gómez et al. reported the isolation of cytosine (48) from the sponge Haliclona tubifera (now H. (Reniera) tubifera) [12] (Figure 8). No biological data were reported for 45–48.

Figure 8. Structures of nucleosides 45–47 and nitrogenous base 48 isolated from the sponges Halichondria magniconulosa (now H. (Halichondria) magniconulosa) and Haliclona tubifera (now H. (Reniera) tubifera), respectively.
2.3.3. Conotoxins

The venomous fish-hunting cone snails that belong to the *Conus* genus are composed of a collection of toxin peptides that serve to immobilize prey by targeting different physiological mechanisms in their neuromuscular system. In this way, ω-conotoxin MVIIA, isolated from *Conus magus*, is commercialized as the synthetic Prialt® (ziconatide), which constituted the first FDA-approved drug that was directly derived from a marine natural product as a pain control drug [1]. On the basis of this background, the research group lead by Aguilar from the Institute of Neurobiology-UNAM at Queretaro in Mexico, reported the isolation of new conotoxins from three different snails, mainly belonging to the *Conus* genus, which were collected along the coasts of the Mexican Caribbean.

Thus, the study of the extract of the venom duct of *Conus delessertii* (now Conasprella delessertii), mollusk collected in Quintana Roo state, allowed Aguilar and collaborators to report four new peptides: conotoxin de13a ([49](#)) and conotoxin de7a ([50](#)), reported in 2005, conotoxin de7b ([51](#)), reported in 2009, and conotoxin de13b ([52](#)), reported in 2013. Conotoxin de13a ([49](#)) contains 32 amino acids (3486.76 Da) and it was defined as a new class of conotoxins. This peptide is characterized by the presence of high content of post-translational modified amino acids, such as 5-hydroxylysine, and the residues of cysteine arranged in a pattern (C-C-C-CC-C-C-C), which were not previously described in conotoxins [25]. On the other hand, conotoxin de7a ([50](#)) contains 28 amino acids (3170.0 Da), with some of them being post-transductionally modified, and a residue (γCCS-) previously found only in two other conotoxins [26]. Conotoxin de7b ([51](#)), bearing 28 amino acids, including six cysteine residues, is characterized by existing in different post-transducatonal modified isomorphs (with molecular masses varying from 3078.6 to 3154.6 Da), some of them containing γ-carboxy-glutamate and/or 4-hydroxyproline at positions 4, 7, and/or 14 [27]. Finally, conotoxin de13b ([52](#)) has the same arrangement of cysteine residues as conotoxin de13a ([49](#)) [28] (Figure 9).

From the extract of the venom duct of a second mollusk, *Conus spurius*, Aguilar and collaborators reported the isolation of twelve new conotoxin derivatives [53–64], from two different places: Quintana Roo and Campeche states. Conotoxin sr5a ([53](#)), which was reported in 2006, is a hydrophobic peptide belonging to the T-1 conotoxin family with a molecular mass of 1616.60 Da and a pair of disulfide bridges. In a biological test in mice, this conotoxin caused a depressed behavioral activity [29]. One year later, two new α-conotoxins of 18 amino acids, SrIA ([54](#)) and SrIB ([55](#)), with a molecular mass of 2202.9 and 2158.8 Da, respectively, were reported. Conotoxins [54](#) and [55](#) were evaluated as antagonists to nicotinic acetylcholine receptors in order to search for new therapeutic alternatives against brain diseases (schizophrenia, nocturnal frontal lobe epilepsy and Alzheimer’s disease). The results suggested not only that these conotoxins can operate as nicotinic acetylcholine receptor inhibitors, but also that they bind to nicotinic acetylcholine receptors with a very high affinity, increasing their intrinsic cholinergic response, and making them excellent model tools for studying toxin-receptor interaction [30]. The fourth new peptide, conotoxin sr7a ([56](#)), with a molecular weight of 3650.77 Da, was reported in 2007, being the first I-conotoxin that was isolated from the Western Atlantic. This peptide produces a stiffening of body, limbs, and tail when intracranially injected into mice [31]. Conotoxin sr7a ([57](#)) containing 32 amino acids (3330.74 Da) and reported in 2007, displays several in vivo effects, such as hyperactivity in mice and paralysis in freshwater snails (*Pomacea paludosa*), while it was inactive in intramuscular trials with the limpet *Patella opea* and the freshwater fish *Lebistes reticulatus* [32]. In contrast, conorfamide-Sr2 (CNF-Sr2, [58](#)), as reported in 2008, with a molecular mass of 1468.70 Da and without cysteine residues, exhibits paralytic activity in the limpet *Patella opea* and produces hyperactivity in the freshwater snail *Pomacea paludosa* and mice [33]. From specimens of *Conus spurius*, collected in Isla Arena, Campeche state, were isolated and identified by reverse transcription polymerase chain reaction, seven conotoxins. Four of them belong to the T-1 conotoxin family, (18V) sr5a ([59](#)), (18T) sr5a ([60](#)), “extended” ([61](#)), and “hydrophilic” ([62](#)), which were reported in 2009 [34], and they are very similar to the conotoxin sr5a ([53](#)). The other three, reported in 2010, were the known conotoxin sr11a ([63](#)) already reported in 2007 [31] and the new conotoxins, sr11b ([64](#)) and sr1lc ([65](#)) [35] (Figure 9).
Finally, Aguilar and collaborators reported in 2009 the isolation of a new peptide, pal9a (65) (3678.84 Da) with 34 amino acids, including six cysteine residues, from a third mollusk, Polystira albida, collected in Campeche state. This is the first P-conotoxin-like turritoxin isolated from a member of the family Turridae from the Western Atlantic [36] (Figure 9).

Figure 9. Structures of conotoxins 49–65 isolated from cone snails belonging to the Conus genus and Polystira albida.
2.4. Biopolymers

Freile-Pelegrín and collaborators reported the characterization of L-carrageenan (66) in 2018, being obtained from the direct extraction of the red algae Solieria filiformis collected at Telchac in the Yucatan state. This polysaccharide shows high antiviral activity against Herpes simplex virus with an EC₅₀ value of 6.3 µg mL⁻¹/0.019 µM [37] (Figure 10).

3. Bioprospecting Overview

A total of 95 scientific documents were recorded and analyzed in this review, including 82 articles, four postgraduate dissertation theses, and nine meeting abstract communications. They describe the reports related to research on pharmacological surveys of extracts, chemical composition, and isolation of marine natural products. A total of 145 species of marine organisms are enclosed, belonging to 12 phyla (Tables 1 and 2), being the most representative Rhodophyta (27%), Chlorophyta (22%), Phaeophyta (17%), and Cnidaria (14%) (Figure 11).

![Distribution of the reported marine organisms by phylum.](image)

|                         | Conus spurius                    | 53–64 (Nitrogen compounds)               | [29–35]    |
|                         | Octopus maya                     | 44 (Nitrogen compound)                   | [23]       |
|                         | Polystira albida                 | 65 (Nitrogen compound)                   | [36]       |
| Porifera (Sponges)      | Halichondria magniconulosa (now H. (Halichondria) magniconulosa) | 45–47 (Nitrogen compounds) | [24] |
|                         | Haliclona tubifera (now H. (Reniera) tubifera) | 6, 10–14 (Polyketides and 48 (Nitrogen compound) | [12] |
|                         | Spongia tubulifera (now S. (Spongia) tubulifera) | 15–21 (Terpenoids) | [16] |
|                         | Teichaxinella morchella (now Axinella corrugata) | 24–35 (Terpenoids) | [18] |
| Phaeophyta (Brown algae)| Dictyota ciliolata               | 22, 23, 36 (Terpenoids)                  | [17]       |
|                         | Lobophora variegata              | 7–9 (Polyketides)                        | [14]       |
|                         | Padina sanctae-crucis            | 36, 37 (Terpenoids)                      | [17]       |
|                         | Turbinaria tricostata            | 36, 37 (Terpenoids)                      | [17]       |
| Rhodophyta (Red algae)  | Solieria filiformis              | 66 (Biopolymer)                          | [37]       |
Table 2. Reported marine species from Yucatan Peninsula related to bioprospecting without determining the chemical composition.

| Domain: Bacteria | Kingdom: Bacteria |
|-------------------|-------------------|
| **Phylum** | **Genus or Species** | **References** |
| Actinobacteria | | |
| Streptomyces | | |
| Saccharomonospora | | |
| Dietzia | | |
| Nocardiopsis | | |
| Pseudonocardia | | |
| Verrucosispora | | |
| Brachybacterium | | |
| Jiangella | | |
| Salinispora | | |

| Domain: Eukarya | Kingdom: Animalia |
|-----------------|-------------------|
| **Arthropoda (Crustaceans)** | | |
| Bathynomus giganteus | [39] |
| Limulus Polyphemus | [40] |

| Chordata (Ascidians) | Trididemnum solidum | [41] |
|----------------------|----------------------|------|

| Domain: Eukarya | Kingdom: Plantae |
|-----------------|-----------------|
| **Cnidaria (Anemones)** | | |
| Actiniidae Gen. sp. nov * | | |
| Anthopleura texensis | [42] |
| Bartholomea annulata | [43–46] |
| Bunodeopsis antillensis | [47] |
| Bunodeopsis globulifera (now Viatrix globulifera) | [48,49] |
| Condylactis gigantea | [50] |
| Lebrunia danae (now L. neglecta) | [47,51] |
| Stichodactyla helianthus | [47,52] |
| Telmatactis bernoni* | [43] |

| **Cnidaria (Corals)** | Millepora alcicornis | [53–57] |
|-----------------------|---------------------|--------|
| Millepora complanata | [53,55,58–62] |
| Porites astreoides | [63] |
| Pseudodiploria strigosa | [63] |
| Siderastrea siderea | [63] |

| **Cnidaria (Jellyfish)** | Aurelia aurita | [64,65] |
|--------------------------|----------------|--------|
| Carybdea marsupialis | [47,66,67] |
| Cassiopea xamachana (now Cassiopea andromeda) | [47,68,69] |
| Linuche unguiculata | [47] |
| Pelagia noctiluca | [70] |

| **Echinodermata (Sea cucumbers)** | Holothuria mexicana (now H. (Halodeima) mexicana) | [71] |
|-----------------------------------|-------------------------------------------------|------|
| Isostichopus badionotus | [72–74] |

| **Mollusca (Mollusks)** | | |
|------------------------|----------------|------|
| Conus austini (now C. cancellatus) | | |
| Conus spurius | [75,76] |
| Gemmula periscelida | [77] |
| Octopus maya | [78] |
| Polystira albida | [75,77] |
| Chlorophyta (Green algae)                                                                 |   |
|------------------------------------------------------------------------------------------|---|
| *Acetabularia schenckii* (now *A. subg. Acicularia schenckii*)                           | [79] |
| *Avrainvillea* cf *digitata* sp.                                                         | [80–83] |
| *Avrainvillea longicaulis*                                                                | [79] |
| *Avrainvillea nigricans*                                                                  | [84] |
| *Caulerpa asheaddii*                                                                     | [79,85] |
| *Caulerpa cupressoides*                                                                   | [79,85,86] |
| *Caulerpa mexicana*                                                                       | [85] |
| *Caulerpa paspaloides*                                                                    | [79,85] |
| *Caulerpa prolifera*                                                                     | [79,85,87] |
| *Caulerpa racemosa*                                                                      | [85] |
| *Caulerpa racemosa var. racemosa*                                                        | [88] |
| *Caulerpa sertularioides*                                                                 | [79,87] |
| *Caulerpa taxifolia*                                                                      | [79] |
| *Cladophora prolifera*                                                                    | [80] |
| *Cladophora vagabonda*                                                                    | [79] |
| *Codium decorticatum*                                                                    | [79,83] |
| *Codium isthmocladum*                                                                    | [85,88,89] |
| *Enteromorpha intestinalis* (now *Ulva intestinalis*)                                     | [79] |
| *Halimeda incrassata*                                                                     | [80–83,85] |
| *Halimeda monile*                                                                         | [79] |
| *Halimeda opuntia*                                                                        | [86] |
| *Halimeda tuna*                                                                            | [79–83,86] |
| *Penicillus capitatus*                                                                    | [85,86] |
| *Penicillus dumetosus*                                                                    | [79–83,90] |
| *Penicillus lamourouxii*                                                                  | [80–83] |
| *Penicillus ptyriformis*                                                                  | [79] |
| *Rhiocephalus phoenic*                                                                   | [81,82] |
| *Rhiocephalus phoenic f brevifolius*                                                      | [80,83] |
| *Udotea conglutinata*                                                                     | [79–83] |
| *Udotea flabellum*                                                                        | [80–83,86,91] |
| *Udotea occidentalis*                                                                     | [85] |
| *Phaeophyta (Brown algae)*                                                                 |   |
| *Dictyopteris jamaicensis*                                                                | [83] |
| *Dictyota bartayresiana*                                                                  | [86] |
| *Dictyota caribae*                                                                        | [80–83,92] |
| *Dictyota cervicornis*                                                                    | [79,86] |
| (now *Canistrocarpus cervicornis*)                                                        |   |
| *Dictyota ciliolata*                                                                      | [79,93,94] |
| *Dictyota cremulata*                                                                      | [79] |
| *Dictyota dichotoma*                                                                      | [89] |
| *Dictyota menstrualis*                                                                    | [85] |
| *Lobophora variegata*                                                                     | [79–83] |
| *Padina boergeseni*                                                                       | [86] |
| *Padina durvillae*                                                                        | [86] |
| *Padina gymnospora*                                                                       | [79,86,88] |
| *Padina pavonica*                                                                         | [83] |
| *Padina perindusiata*                                                                     | [80–83,92] |
| *Padina sanctae-cruis*                                                                    | [93,94] |
| *Sargassum cymosum*                                                                       | [86] |
| *Sargassum filipendula*                                                                   | [84–86,88,92] |
| *Sargassum fluitans*                                                                      | [80–83,86,93–96] |
| *Sargassum hystrix*                                                                       | [84,86] |
| *Sargassum polyceratium*                                                                  | [86] |
| *Sargassum pteropleuron*                                                                  | [79,86] |
| *Sargassum ramifolium*                                                                    | [79] |
| *Sargassum vulgar*                                                                        | [86] |
| *Turbinaria tricostata*                                                                   | [79,86,93,97] |
| *Turbinaria turbinata*                                                                    | [80–83,86,92] |
Table 2. Cont.

| Rhodophyta (Red algae) |  |
|------------------------|--------------------------|
| Acanthophora spicifera  | [79]                     |
| Agardhiella sp.         | [80–83]                  |
| Agardhiella subalata    | [89]                     |
| Bryothamnion triquetrum (now Alsidian triquetrum) | [79–83,85,86,89] |
| Ceramium nitens         | [79–83,85]               |
| Chondria salicornoides  | [79,80,82,83]            |
| Chondria atropurpurea   | [79]                     |
| Chondria baileyana      | [79]                     |
| Chondrophycus papillosus (now Palisada perforata) | [79] |
| Chondrophycus poiteaui (now Yuzurua poiteaui) | [79] |
| Dǐgenea simplex         | [79,85,86]               |
| Eucheuma isiforme (now Eucheumatopsis isiformis) | [79–83,85,88,98] |
| Gracilaria blodgettii   | [99]                     |
| Gracilaria bursa-pastoris | [79]          |
| Gracilaria caudata      | [79–83,85]               |
| Gracilaria cervicornis   | [80–83,99]               |
| Gracilaria cornea (now Crassiphycus corneus) | [79,85,88,100] |
| Gracilaria crassissina (now Crassiphycus crassissimus) | [99,100] |
| Gracilaria cylindrica   | [79]                     |
| Gracilaria damaeccornis* | [80–83]                  |
| Gracilaria sp.          | [80–83]                  |
| Gracilaria tikiolaiæ    | [79]                     |
| Gracilaripsis tenuifrons | [79,101]                 |
| Halymenia floresia (now H. floresii) | [79,80,82–85,89,102, 103] |
| Heterosiphonia gibbesii | [79–83]                  |
| Hydropuntia cornea (now Crassiphycus corneus) | [80–83,95] |
| Hypnea musciformis       | [104]                    |
| Hypnea spinella          | [79]                     |
| Jania capillacea         | [80–83]                  |
| Laurencia intricata      | [79,86,87]               |
| Laurencia microcladia    | [80–83]                  |
| Laurencia obtusa         | [79,84–86]               |
| Laurencia papillosa      | [86]                     |
| (now Palisada perforata) |                         |
| Laurencia poiteaui      | [85,86]                  |
| (now Palisada poiteaui)  |                         |

* Organisms not found in World Register of Marine Species (WORMS database) [109].

The mollusk *Conus spurius* and two algae, *Halymenia floresia* (now *H. floresii*) and *Sargassum fluitans*, with nine reports each, were the most reported species. The coral *Millepora complanata* and eight algae, *Halimeda tuna*, *Penicillus dumetosus*, *Udotea flabellum*, and *Bryothamnion triquetrum* (now
Alsidium triquetrum), Ceramium nitens, Eucheuma isiforme (now Eucheumatopsis isiformis), Gracilaria caudata (now Crassiphycus caudatus), Lobophora variegata, and Turbinaria turbinata, with 6–8 reports each, following the list as it is shown in Figure 12.

![Graph showing number of publications per year.](image)

**Figure 12.** Number of publications of reported marine species organized by phylum. Only those species that have three or more reports are displayed.

From the territorial distribution point of view, the highest number of reports corresponds to marine organisms that were collected at the coast of the Yucatan state (38%), followed by the coasts of Quintana Roo state (36%) and, finally, the coasts of Campeche state (4%). However, 22% of the reports did not specify the state where the marine organisms were collected (Figure 13).

![Pie chart showing geographic distribution.](image)

**Figure 13.** Geographic distribution of collections sources in percentage by state.

Figure 14 displays the number of reports per year. As far as we know, the first report was published in 1981 and, since then, the number of publications related to the search for natural marine products of the Yucatan Peninsula has been increasing. However, this increase was not constant, being the years 2007, 2013, 2014, and 2016, with seven publications each, when more reports were published.
4. Conclusions

The present review represents the first comprehensive report of natural products that have been isolated from marine organisms collected along the coasts of the Yucatan Peninsula, covering literature up to mid-2019. As a result of 38 years of investigations of marine organisms that were collected in the Yucatan Peninsula, 66 marine natural products were isolated from 18 species belonging to eight different phyla (Proteobacteria (Acinetobacter sp.), Chordata (ascidian: Stomozoa murrayi (now Stomozoa rosola)), Cnidaria (Pterogorgia anceps), Echinodermata (Astichopus multifidus and Holothuria floridana (now H. (Halodeima) floridana)), Mollusca (Conus delessertii (now Conasprella delessertii), Conus spurius, Octopus maya, and Polystira albida), Porifera (Halichondria magniconulosa (now H. (Halichondria) magniconulosa), Haliclona tubifera (now H. (Reniera) tubifera), Spongia tubulifera (now S. (Spongia) tubulifera) and Teichaxinella morcella (now Axinella corrugata)), Rhodophyta (Soliera filiformis), and Phaeophyta (Dictyota ciliolata, Lobophora variegata, Padina sanctae-crucis, and Turbinaria tricostata) (Table 1). Out of the 66 marine natural products identified, 26 correspond to structures that were not previously reported. These 26 new chemical entities correspond to three aliphatic polyketides (1–3), one glycolipid (7), two diterpenes (15, 16), two steroids (24, 25), one triterpenoid saponin (40), and 17 conotoxins (49–65).

Figure 15 displays the overall biogenetic distribution of the reported compounds. The terpenoid biogenesis is again the most prominent pathway (40.9%), enclosing the diterpenes-sterterpenes (nine compounds), steroids (14 compounds), and triterpenoids saponins (four compounds). On the other hand, conotoxins, with 17 compounds (25.8%) constitute the largest group of the reported natural products.

The biological studies of the isolated compounds are focused on cytotoxic or antiproliferative activities (diterpenes 15, 18, 20, 22, and 23; steroids 36 and 37, and triterpenoids saponins 38 and 39), the antimicrobial, antifouling, antipredatory (deterrent), and antialgal activity (indole derivative 42 and...
the antiprotozoal activity (glycolipids 7–9), neurotoxic activity (indole derivative 44), behavioral activity in animal models (conotoxins 53, 56–58), and finally in the interesting pharmacological activities against brain diseases of the new conotoxins 54 and 55, and the high antiviral activity of the known biopolymer L-carrageenan (66).

As a concluding remark, this review shows the potential of the Yucatan Peninsula as an interesting source of new marine natural products, not only because of its unique and rich diversity of marine organisms, but also due to the small number of works that have been published so far, which indicates that this area of research has been poorly investigated. For these reasons, the marine biodiversity of the Yucatan Peninsula can be considered as a poor exploited source of new bioactive marine natural products, which could be the base of the development of new drugs.

**Author Contributions:** Conceptualization, C.J., D.P-P. and J.R.; Funding acquisition and Resources, J.R. and C.J.; Writing—original draft, D.P-P.; M.P-P., O.A.L.-R. Writing—review & editing, D.P-P.; J.R. and C.J. All authors have read and agree to the published version of the manuscript.

**Funding:** This work was supported by grants RTI2018-093634-B-C22 (AEI/FEDER, EU) from the State Agency for Research (AEI) of Spain, co-funded by the FEDER Programme from the European Union, and GRC2018/039 and ED431E 2018/03 of CICA-INIBIC strategic group from Xunta de Galicia. D.P-P. received a fellowship from the program National Council of Science and Technology (CONACYT) of Mexico and the Secretariat of Research, Innovation and Higher Education (SIIES) of Yucatan (Mexico). O.A.L.R. received a financial support from MostMicro unit. Project LISBOA-01-0145-FEDER-007660 of Portugal.

**Conflicts of Interest:** The authors declare no conflict of interest.
