College of Plant Protection, Shandong Agricultural University, Key Laboratory of Pesticide Toxicology and Application Technique, Taian, China

The diamondback moth (DBM), *Plutella xylostella* L., is an important pest of cruciferous vegetables, and population control mainly depends on chemical pesticides. Emamectin benzoate is a highly effective insecticide used for controlling DBM. However, it is unknown how the sublethal effects of low concentration residues of emamectin benzoate on DBM. So the population development sublethal effects of emamectin benzoate, at LC50, LC10, and LC20 with concentrations of 0.014 mg/L, 0.024 mg/L and 0.047 mg/L, respectively, on adult DBM and their progeny were investigated in this study. The pupal weight, pupal period, female fecundity, and vitellin content of the F0 DBM generation increased significantly compared to the control. And the single female oviposition number of DBM was increased by 20.21% with LC20 treatment. The pupation rate, adult longevity and ovariole length of the treatment groups decreased significantly. The fecundity of DBM in the treatment groups increased, and this increased the population by a presumptive 13.84%. Treatment also led to the shortening of ovarioles and the reduction of egg hatching, and increased pupal weight in the F1 generation. We concluded that the effects of sublethal/low concentration emamectin benzoate on the different life stages of DBM were variable, and the reproductive hormesis on DBM adults were attractive findings.

**Introduction**

The diamondback moth (DBM), *Plutella xylostella* L., is a widely distributed lepidopteran pest that causes serious damage to cruciferous vegetables. It has strong adaptability of host, long-distance migration, and overlapping generations (Furlong et al., 2013). DBM control relies on chemical insecticides. However, excessive pesticide use has selected for DBM resistance to more than 90 pesticides (Whalon et al., 2019).

Studies have found that pesticide applications usually induce strong lethal effects in most of arthropods. It primarily through direct mortality of exposed arthropods and a variety of sublethal physiological biological, and/or behavioral effects on arthropod...
concentration were also studied (Wang et al., 2011; Zhang et al., 2021a). Pesticide applications can significantly impact the effectiveness of biocontrol agents in most agroecosystems (Lu et al., 2012; Huang et al., 2020). It may also influence habitat shifts, induces hormesis in insect pests, resistance development, and direct and indirect interactions between species within food webs. Some insecticides may also disrupt biological control of secondary pests, leading to a secondary pest outbreak (Wang et al., 2017; Liang et al., 2021; Liu et al., 2022). Emamectin benzoate on DBM remains unknown until now. In this paper, we studied the effects of sublethal/low concentrations of emamectin benzoate, at LC10, LC15, and LC20 with concentrations of 0.014 mg/L, 0.024 mg/L and 0.047 mg/L, respectively, on the population development of DBM, and hope carry out a science assessment of its application on DBM, avoid or delay resurgence of DBM in the field.

Materials and methods

Insect

P. xylostella was collected from the experimental station of the South campus of Shandong Agricultural University in 2006 and cultured indoors on radish seedlings and cabbage leaves without pesticide exposure. The insect rearing room was maintained at 25 ± 2°C, relative humidity 60%–70%, and a photoperiod of 14:10 h (L:D). The adults were fed on 10% honey: water.

Insecticides and reagents

Emamectin benzoate (95.0%) was provided by Qingdao Dingfeng Biotechnology Co., Ltd. Shandong Province, China. Acetone, ether, and other solvents were analytical grade and were purchased from Tianjin Damao Chemical Reagent Factory, Tianjin, China.

Bioassay of acute toxicity

Acute toxicity was determined by the leaf dipping method (Liang et al., 2003). Emamectin benzoate was dissolved in acetone to prepare a concentrate of 200 mg/L. The concentrate was serially diluted with 1% Tween 80 aqueous solution to obtain emamectin benzoate solution concentrations of 0.05, 0.10, 0.20, 0.40 and 0.80 mg/L. Fresh cabbage leaves were cut into 5.0 ± 0.5 cm disks, dipped in the solution for 10 s and held vertically to allow excess solution to drip off, and placed on a rack to dry. Twenty third-instar DBM larvae were added to each culture dish containing a treated leaf disk. An aqueous solution without emamectin benzoate used as the negative control. After 72 h exposure on the cabbage leaves treated with the different concentration of emamectin benzoate, counted the surviving larvae that moved when touched slightly, and transferred to fresh leaves for subsequent experiments.
Bioassay of sublethal effects on DBM

Thirty third-instar DBM larvae were treated with emamectin benzoate for 72 h using the same leaf dip method as described above at sublethal/low concentrations of LC5, LC10, and LC20, respectively. The effects of the sublethal/low concentrations of emamectin benzoate on DBM development were determined. These effects included pupation rate, pupal weight, pupal period, adult emergence rate, adult survival number, single female oviposition number, adult longevity, eggs hatching rate, larval survival rate, and larval development duration. Both F0 and F1 generations were studied. An aqueous solution without emamectin benzoate was used as the control.

After the emergence of the treated insects, select one couple of male and female adults randomly eclosing on the same day, and put the couple into a can bottle with fresh cabbage leaves, providing with 10% honey solution. When the female adult begins to lay, count the number of eggs laid and the number of eggs hatched every 24 h until the adult died. Each treatment was 5 couple of adults and repeated 3 times independently.

Ovary anatomy and vitellin content determination

Third-instar DBM larvae were exposed to emamectin benzoate for 72 h using the leaf dip method mentioned above at sublethal/low concentrations of LC5, LC10, and LC20, and surviving female adults were collected. The female adults were anesthetized with CO2 and the thorax/abdomen was removed with ophthalmic surgical scissors. The abdomen was placed on a glass slide coated with physiological saline. Then, the end of the abdomen was squeezed gently with an insect pin and the ovarioles were removed. The fat particles adhering to the ovarioles were removed with dissecting forceps and the ovarioles were stained with safranine dye solution for 5 min. Excess dye solution was then washed off the ovarioles. The ovarioles were observed and photographed with a continuously variable magnification stereomicroscope (SZX 10). The length or width diameter of mature eggs and ovarioles lengths were measured with ImageJ image processing software.

The vitellin content at 0–96 h after female emergence was determined using an insect vitellin linked immunoassay (ELISA) kit (Shanghai Meilian Biotechnology Co., Ltd., Shanghai China) according to the directions of the kit.

Data analysis

Three independent replicates were used for each test. Probit analysis was used to determine the value of lethal concentration. All biological traits data were processed using SPSS V16.0 (SPSS, Inc., Chicago, IL, USA), and the results are shown as the mean ± standard deviation (SD, n = 3). All biological traits data were subjected to the analysis of variance (ANOVA) test, and mean differences were evaluated by Tukey’s multiple comparison test (p = 0.05). Significance was indicated at p < 0.05.

Results

Toxicity

The toxicity of emamectin benzoate to the third-instar DBM larvae was determined by the leaf dip method. After 72 h exposure the LC50 was 0.173 mg/L, and the LC5, LC10, and LC10 values were also obtained (Table 1).

Sublethal effects of emamectin benzoate on the F0 generation of DBM

Third-instar DBM larvae were treated with emamectin benzoate at the sublethal/low concentrations of LC5, LC10, and LC20. The corrected larvae survival rate was 93.3%, 88.7% and 81.3%, respectively. The pupation rate of DBM larvae decreased with increased treatment concentration. The pupation rate of the LC10 and LC20 treatments was significantly (F = 7.47, df = 11, p = 0.010) lower than the control group (Figure 1A). The pupa weight of LC10 and LC20 treatment groups increased significantly (F = 16.49, df = 79, p = 0.0001) by 10.53% and 14.63%, respectively (Figure 1B), compared to the control. The pupal period of DBM in the LC10 treatment was significantly (F = 3.70, df = 79, p = 0.015) longer than the control group (Figure 1C). However, the three treatment groups had no significant (F = 2.60, df = 11, p = 0.125) effect on the adult emergence rate (Figure 1D).
pupation and adult emergence, single female oviposition number in the LC20 treatment group was 192.7 ± 3.37. It was increased 20.21% compared with the control (Figure 1E). The eggs laying peak in the LC20 group was the same as that of the control, but the daily oviposition number increased and the egg laying hours was prolonged by 7.31% (Figure 1F). When compared to the control, the egg hatching rate decreased by 4.08%; however, the average number of larvae in the F1 generation increased by 22.19, which ultimately led to DBM quantity presumptive increase of 13.84%.

Third-instar DBM larvae were exposed to deposits of emamectin benzoate applied at LC5, LC10, and LC20. After survivors developed into adults, the longevity of female adults in the LC20 group was determined to be significantly (F = 7.05, df = 39, p = 0.0008) shorter than control longevity. The male adult longevity in the three treatments was shortened to various degrees (Figure 2A). The vitellin content in adult females was determined by ELISA. With extension of the time after eclosion, the vitellin content in the LC20 treatment group was significantly (72 h: F = 24.17, df = 11, p = 0.0002) higher than in the control, and the maximum increase was 19.00%. The vitellin content of the other groups were significantly (LC10 24 h: F = 47.59, df = 11, p = 0.0001) changed with the eclosion time (Figure 2B).

Sublethal effects of emamectin benzoate on the F1 generation of DBM

Emamectin benzoate treatment affected the length or width diameter of adult mature eggs. Compared to the control, the

Different letters on right side of the same column indicate significance ($p < 0.05$).
length of mature ovarioles in the LC20 group was shortened by 15.60% (Figure 3). Emamectin benzoate treatment did not significantly (F = 0.16, df = 39, p = 0.925) affect the mature egg ratio of the F1 generation, but it significantly (F = 8.611, df = 11, p = 0.006) decreased egg hatchability. The treatments had no significant (F = 0.353, df = 11, p = 0.789) effects on larval survival (Table 2).

The pupa weight of the F1 offspring in LC20 group was significantly (F = 3.187, df = 79, p = 0.028) increased. However, there was no significant effect on the pupation rate, pupal period, pupal emergence rate, single female oviposition number, female oviposition period, and adult longevity of the F1 offspring (Table 3).

Discussion

Only a small proportion of chemical pesticide applied directly kills target pests. Most pesticide residue remains in the environment and it may exert sublethal effect on surviving insects. A sublethal/low dose of residual insecticide can effect insect development, morphology, pupa weight, longevity, and fecundity (Zhang et al., 2022). The sublethal effects of pesticides influence the biological characteristics and population development of insects and can provide insight into optimal pesticide use.

Treatment of second-instar Spodoptera litura larvae with sublethal doses of chlorantraniliprole or indoxacarb increased the pupal period and increased pupal weight (Moustafa et al., 2021). The fecundity of Laodelphax striatellus was significantly decreased by imidacloprid LC50 treatment. However, the fecundity was significantly increased when the test insects were treated with an LC10 dose of imidacloprid (Zhang et al., 2021b). When the third-instar DBM larvae were treated with a LC30 dose of emamectin benzoate in this study the development time of larvae was prolonged by 17.0 ± 3.0 h, the pupation rate of F0 larvae was decreased by 9.40%, the pupa weight was increased by 14.63%, the average single female oviposition number increased by 30.9 eggs, and the longevity of female adults was shortened by 10.10%. The egg hatch rate decreased by 4.08%, but the number of larvae in the F1 generation increased. The survival rate, pupation rate and pupae emergence rate of the F1 generation were similar to the control, and this could ultimately lead to a presumptive population increase of 13.84%. Sublethal concentration (LC10 and LC30) exposures of emamectin benzoate had a significant negative impact on the larval, protonymph, and deutonymph developmental periods on Panonychus citri (Khan et al., 2021). Female fecundity of P. citri was decreased, and the adult pre-oviposition period and total pre-oviposition period were increased in the sublethal treatments. The age-stage specific survival rates (Sij), age-specific fecundity (Mij), net reproductive rate (R0), age-stage specific life expectancy (Eij), and age-stage reproductive value (Vi,j) was reduced by LC10 and LC30 exposure (Khan et al., 2021), that of the results were different from this study. The reason need to be further study.

A low concentration nitenpyram induced transgenerational hormesis effects in terms of fitness-related traits and insecticide tolerance in Nilaparvata lugens after exposure to the LC20 concentrations for six generations (Gong et al., 2022), but, we did not find transgenerational hormesis in DBM by emamectin benzoate treated. It was found that insecticide-induced hormesis in life history traits may augment the development of insecticide tolerance or resistance in pest insects, allowing fitter individuals to survive and reproduce, with significant management and environmental implications (Guedes et al., 2016). The reproduction hormesis of parental generation maybe one of reasons of DBM resurgence. Based on this case, a few of control policies conform to IPM strategies could be used, e.g., combination use of compatible insecticides and biological control agents, attract-and-kill control strategies, development of new safer, environmentally friendly and target-specific insecticides or cultivation safety transgenic crops.

Insect fecundity is mainly regulated by the synthesis of vitellogenin (Vg) and vitellin (Vn) (Jing et al., 2021). Vitellogenin is synthesized in the fat body of adult females and released into the hemolymph. It is then absorbed by oocytes through special channels to synthesize vitellin to provide essential nutrients for egg development (Tufail et al., 2014). The expression of vitellogenin and vitellogenin receptor genes were significantly increased in a flubendiamide resistant DBM strain compared to a susceptible strain, and vitellin content also increased in the resistant strain (Sun et al., 2020). The LC10 of emamectin benzoate can reduce the transcription of CsVg and CsVgR at 24-h, 48-h, and 72-h exposure and decrease the egg production of C. sinensis (Yao et al., 2018). After injecting 20-hydroxyecdysone into silkworm larvae, the Vg content in the hemolymph increased, and the Vn content in the ovary also increased. This led to a significant increase in the total egg weight (Shen et al., 2014), this is similar to the results of the present study. When DBM larvae were treated with the LC10 of emamectin benzoate, the number of eggs laid by single adults was significantly increased compared to the control. The Vn content of the LC10 DBM treatment after adult eclosion was significantly higher than that of the control. This indicated a direct correlation between the Vn content and egg production. Similar results have been elaborated in many other insecticide-exposed insects (Zhou et al., 2020).

In conclusion, the effects of sublethal/low concentration emamectin benzoate on the different life stages of DBM were variable, and the reproductive hormesis on DBM adults were attractive. However, the reason of hormesis deserve further detailed study on insect biology and genetics in combination with DBM resistance. This case makes it necessary for us to re-understand the population development of P. xyllostella. In addition, combination use of compatible insecticides and
biological control agents, 'attract-and-kill' control strategies, development of new safer, environmentally friendly and target-specific insecticides, one or more these policies can be selected for the control of DBM in fields.
