Abstract

Background: To find new diagnostic markers for idiopathic membranous nephropathy (IMN) and also conduct preliminary explorations into the possible pathogenesis of IMN by comparing the expression of microRNA-451a (miR-451a), miR-106a, miR-19b, miR-17, and phosphatase and tensin homolog (PTEN) protein in the serum of patients with IMN and healthy controls.

Methods: The expression levels of miR-451a, miR-106a, miR-19b, and miR-17 in the serum of patients in the IMN group (n = 55, age: 50.2 ± 12.1 years) and the control group (n = 58, age 47.4 ± 13.1 years) were measured by quantitative real-time polymerase chain reaction (qRT-PCR), and the concentration of serum PTEN protein was determined by enzyme-linked immunosorbent assay (ELISA).

Results: Compared with the control group, the expression of miR-106a, miR-19b, and miR-17 was decreased significantly in the IMN group, whereas PTEN protein concentration was increased significantly in the IMN group. The areas under the receiver operating characteristic curve (AUC) of serum miR-106a, miR-19b, miR-17, and PTEN were 0.66 (95% confidence interval [CI], 0.56–0.76), 0.81 (95% CI, 0.73–0.89), 0.69 (95% CI, 0.59–0.79), and 0.86 (95% CI, 0.79–0.93), respectively. The level of serum PTEN protein was negatively correlated with the expression of miR-106a and miR-19b. PTEN concentration was positively correlated with serum urea (Urea), creatinine (Crea), cystatin C (Cysc), 24 h urine total protein (24 h-UP) and negatively correlated with albumin (Alb) and estimated glomerular filtration rate (eGFR).

Conclusions: MiR-106a, miR-19b, miR-17, and PTEN are involved in the pathogenesis of IMN and may become new biomarkers for the diagnosis of IMN.

KEYWORDS
idiopathic membranous nephropathy, microRNA-106a, microRNA-17, microRNA-19b, microRNA-451a, phosphatase and tensin homolog protein
1 | INTRODUCTION

In recent years, with the incidence of membranous nephropathy (MN) gradually increasing, MN is now the main cause of nephrotic syndrome in adults after IgA nephropathy (IgAN). The main clinical features of MN are extensive proteinuria and a gradual decline in renal function. Depending on the etiology, MN can be divided into idiopathic membranous nephropathy (IMN) and secondary membranous nephropathy (SMN). The pathogenesis of IMN is still unclear.

The onset of IMN is usually insidious, and renal impairment often develops within 5–10 years. Early diagnosis and timely treatment play a crucial role in preventing or delaying renal failure. Renal biopsy is the gold standard for diagnosis of IMN. However, since it is an invasive procedure, there are certain limitations in the application of IMN, including clinical contraindications, such as solitary kidney, small kidney, mental illness, severe hypertension. The discovery of phospholipase A2 receptor antibody (anti-PLA2R) in the serum is a milestone in the noninvasive diagnosis of IMN. However, the diagnostic sensitivity of anti-PLA2R in IMN varies among different diagnostic centers, ranging from 82% to 51%. Therefore, it is still of great practical significance to find safe, rapid, and effective noninvasive indicators for diagnosing IMN.

MicroRNA (miRNA) is an endogenous non-coding small RNA, consisting of 22–23 ribonucleotides. Its main function is to inhibit or promote important biological processes in the body, such as cell differentiation, proliferation, and apoptosis, by regulating gene expression. Studies suggest that miRNAs are involved in the pathogenesis of several kidney diseases. Increasing evidence suggests that miRNAs play important roles in the pathogenesis and progression of IMN. Studies have found that compared with healthy controls, miR-217 in renal podocytes, and miR-82, miR-98, miR-89, miR-84, miR-152, and miR-15 in peripheral blood lymphocytes of patients with IMN were significantly differently expressed. Phosphatase and tensin homolog (PTEN) protein is a classic pro-apoptotic protein, which can promote cell apoptosis and promote apoptosis of many kinds of cells.

2 | MATERIALS AND METHODS

2.1 | Subjects

Our study was comprised of 2 groups, the IMN and control groups. Between May 2017 and October 2018, 55 patients were diagnosed initially as IMN by renal biopsy at the Department of Nephrology of Shengjing Hospital of China Medical University; these patients were included in the IMN group. A total of 58 healthy individuals who visited the physical examination center were included in the control group. Patients in the IMN group did not have IgA nephropathy, diabetic nephropathy, lupus nephritis, allergic purpuric nephritis, FSGS, antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis, severe heart and brain disease, liver or hematopoietic disease, pregnancy, cancer, or other autoimmune diseases.

Fasting venous blood (2 ml) was drawn from patients in the IMN group at admission. The blood samples were centrifuged at 1200 g for 10 min, and the serum was separated and stored in a −70°C deep freezer. The leftover serum from healthy individuals after physical examination was collected and stored in a −70°C freezer. All samples were collected and tested centrally in one laboratory. This study was approved by the ethics committee (approval number: 2019PS143K) of Shengjing Hospital of China Medical University.

2.2 | Clinical data collection

We collected the clinical and laboratory data, including age, gender, serum Alb, Urea, Crea, Cysc, eGFR (estimated using CKD-EPI formula based on creatinine and cystatin C, 2012), and 24 h-UP from IMN patients at admission and healthy controls.

| TABLE 2 | Clinical data of patients in the IMN and control groups |
|----------------|-----------------------------------------------|
| IMN group | Control group | p value |
| N | 55 | 58 | – |
| Age | 50.2 ± 12.1 | 47.4 ± 13.1 | 0.244 |
| Gender (M: F) | 27: 28 | 29: 29 | 0.923 |
| Alb (g/L) | 24.8 ± 5.2 | 46.2 ± 2.5 | <0.0001 |
| Urea (mmol/L) | 6.9 ± 2.9 | 4.9 ± 1.1 | <0.0001 |
| Crea (μmol/l) | 68.7 ± 15.9 | 68.9 ± 12.6 | 0.957 |
| Cysc (mg/L) | 1.28 ± 0.38 | 0.80 ± 0.11 | <0.0001 |
| eGFR (ml/ min/1.73 m²) | 77.36 ± 19.92 | 104.09 ± 14.21 | <0.0001 |
| 24 h-UP (mg/24 h) | 5.0 ± 3.3 | – | – |

Note: “N” represents the number of patients in each group. Age, Alb, Urea, Crea, Cysc, eGFR, and 24 h-UP followed a normal distribution and were expressed as mean ± standard deviation. p < 0.05 was considered statistically significant.

aComparisons made by t test.

bComparisons made by χ² test.
2.3 | Methods

2.3.1 | Detection of miR-451a, miR-106a, miR-19b, and miR-17

**Total RNA extraction and cDNA synthesis**

Total RNA was extracted by using miRNeasy Serum/Plasma Kit (Qiagen, Valencia, CA, USA). MiRNA First Strand cDNA Synthesis (Tailing Reaction) (Sangon Biotech, Shanghai, China) was used to reverse transcribe the extracted miRNA into cDNA. All operations were carried out according to the kit instructions.

**Quantification of miRNA by quantitative real-time polymerase chain reaction (qRT-PCR)**

To evaluate the expression of miR-451a, miR-106a, miR-19b, and miR-17 in the serum, qRT-PCR was carried out using 2 × SG Fast qPCR Master Mix Low Rox and ABI 7500 Real-Time PCR System (Applied Biosystems, Foster city, CA, USA). U6 was used as an internal reference. The primers of miR-451a, miR-106a, miR-19b, miR-17, U6 R, and U6 F were designed and synthesized by Sangon Biotech; the sequences are shown in Table 1. The reaction was carried out in three steps: 95°C for 3 min, 1 cycle; followed by 95°C for 3 s, 60°C for 30 s, 40 cycles. The relative expressions of miR-451a, miR-106a, miR-19b, and miR-17 were calculated by the $2^{-\Delta\Delta C_T}$ method.\(^{23}\)

2.3.2 | Detection of serum PTEN protein

Enzyme-linked immunosorbent assay (ELISA) was used to detect serum PTEN by TECAN automated enzyme immunoassay analyzer (TECAN Corporation, Switzerland). The PTEN kit was purchased from Wuhan Cloud Cloning Technology Co., Ltd., Hubei province, China. The entire operation was conducted according to the kit instructions.

2.4 | Statistical analysis

Quantitative data that followed a normal distribution are expressed as mean ± standard deviation ($\bar{X} \pm S$) and were analyzed using the t test. Qualitative data are expressed as percentages and were analyzed using the $\chi^2$ test. Correlation analyses were conducted using GraphPad Prism 7.0 (GRAPHPAD Corporation, USA). The diagnostic performance of differential biomarkers in IMN was evaluated by receiver operating characteristic curve (ROC) analysis, and statistical graphs were made using GraphPad Prism 7.0. The areas under the ROC (AUC) and the correlation analysis were compared using the Z test. All statistical analyses were performed using SPSS 17.0 (IBM Corporation, USA). \(p < 0.05\) was considered statistically significant.
3 | RESULTS

3.1 | Clinical data of the IMN and control groups

Compared with the control group, serum Alb and eGFR were significantly reduced, and Urea and Cysc were significantly increased in the IMN group (Table 2). There were no statistically significant differences in serum Crea, age, and gender between the two groups (Table 2).

3.2 | The expression of serum miR-106a, miR-19b, and miR-17 in IMN patients was significantly lower than that in healthy controls, and miR-19b had the highest diagnostic performance

Compared with the control group, the relative expressions of miR-106a (IMN group: 0.83 ± 0.67, control group: 1.19 ± 0.74, p = 0.0077, Figure 1A), miR-19b (IMN group: 0.53 ± 0.53, control group: 1.12 ± 0.65, p < 0.0001, Figure 1B), and miR-17 (IMN group: 0.78 ± 0.56, control group: 1.17 ± 0.61, p = 0.0006, Figure 1C) were significantly reduced in the IMN group. However, serum miR-451a expression was not significantly different between the two groups (IMN group: 1.19 ± 1.11, control group: 1.16 ± 0.71, p = 0.84, Figure 1D).

3.3 | The concentration of serum PTEN in IMN patients was significantly higher than that in the control group, and it had a high diagnostic performance in IMN

Compared with the control group, the concentration of serum PTEN was significantly increased in the IMN group (IMN group: 2.93 ± 1.30 ng/ml, control group: 1.48 ± 0.62 ng/ml, p < 0.0001,

![Figure 2](image)

**Figure 2** The diagnostic performance of miR-106a, miR-19b, and PTEN in IMN. (A) serum miR-106a, AUC 0.66 (95% CI, 0.56–0.76); (B) serum miR-19b, AUC 0.81 (95% CI, 0.73–0.89); (C) serum miR-17, AUC 0.69 (95% CI, 0.59–0.79); (D) serum PTEN, AUC 0.86 (95% CI, 0.79–0.93).
Figure 3). Furthermore, we evaluated the diagnostic performance of serum PTEN in IMN by ROC analysis; the AUC of PTEN (Figure 2D) was 0.86 (95% CI, 0.79–0.93). This indicates that serum PTEN is a potential diagnostic marker of IMN.

3.4 | The level of serum PTEN was negatively correlated with the expression of miR-106a and miR-19b

In addition, we analyzed the correlation between the serum PTEN and miR-106a, miR-19b, miR-17, respectively. The results showed that the concentration of serum PTEN was negatively correlated with the expression of miR-106a ($r = -0.2196$, $p = 0.0194$, Figure 4A) and miR-19b ($r = -0.3693$, $p < 0.0001$, Figure 4B). There was no correlation between PTEN and miR-17 ($r = -0.1419$, $p = 0.1339$, Figure 4C).

3.5 | The concentration of serum PTEN was positively correlated with serum Urea, Crea, Cysc, and 24 h-UP, and negatively correlated with Alb and eGFR

We also analyzed the correlation between serum PTEN and Alb, Urea, Crea, Cysc, eGFR, 24 h-UP, respectively. The results showed that serum Urea, Crea, Cysc, and 24 h-UP were positively correlated with PTEN; the correlation coefficients were Urea ($r = 0.4405$, $p < 0.0001$, Figure 5A), Crea ($r = 0.3091$, $p = 0.0009$, Figure 5B), Cysc ($r = 0.7007$, $p < 0.0001$, Figure 5C), and 24 h-UP ($r = 0.4093$, $p = 0.0019$, Figure 5D). Serum Alb and eGFR were negatively correlated with PTEN; the correlation coefficients were Alb ($r = -0.6375$, $p < 0.0001$, Figure 5E), eGFR ($r = -0.6354$, $p < 0.0001$, Figure 5F).
4 | DISCUSSION

In this study, we found compared with the healthy control group, the relative expressions of serum miR-106a, miR-19b, and miR-17 were significantly decreased in the IMN group, whereas the concentration of PTEN protein was significantly increased. And the diagnostic performance of miR-106a, miR-19b, miR-17, and PTEN in the IMN was 0.66, 0.81, 0.69, and 0.86, respectively.

IMN belongs to glomerular diseases. The injury and apoptosis of podocytes play an important role in the occurrence and development of glomerular diseases, such as MN, IgAN, and FSGS. As important regulators of pro-apoptotic gene expression, miR-106a, miR-19b, and miR-17 play a crucial role in cell proliferation and apoptosis. PTEN protein inhibits the development of tumor cells by antagonizing the activity of phosphorylated enzymes, and the expression of PTEN gene is regulated by miRNAs. K. Brinkmann et al. found that missing miR17-92 clusters resulted in the loss of hematopoietic stem cells. In a study on chronic myeloid leukemia, G. Guo et al. confirmed that miR-106a, miR-106b, and miR-17 could inhibit the expression of PTEN gene and promote the proliferation of leukemic cells. J. Yuan et al. found that abnormally elevated levels of miR-19b and miR-20a in the serum of multiple myeloma patients can inhibit apoptosis of multiple myeloma cells by targeting PTEN, thereby inducing tumorigenesis. MIIR-19b promotes cell survival and inhibits cell apoptosis by targeting PTEN via regulation of the PI3K/AKT pathway, thus having significant neuronal protective effects. Therefore, our results suggested that miR-106a, miR-19b, miR-17, and PTEN were involved in the pathogenesis of IMN, and maybe new biomarkers for the diagnosis of IMN, especially miR-19b and PTEN.

Filtration is the main function of glomeruli, and the injury and apoptosis of podocyte is one of the main causes of the decreased glomerular filtration function. Serum Cysc and eGFR (CKD-EPI Cr-Cysc, 2012) are the more sensitive indexes used to evaluate GFR and could detect early renal damage; 24 h-UP and serum Alb reflect changes in glomerular filtration function through protein loss. Serum Urea and Crea have low molecular weight and can pass freely through the glomerular filtration membrane; however, they are affected by exogenous intake, tubular reabsorption and excretion, and powerful reserve function of the kidney; they increase only when the GFR drops below 50% of normal. Therefore, serum Urea and Crea are the least sensitive and specific indicators in reflecting glomerular filtration function.

In order to explore the possible pathogenetic roles of miR-106a, miR-19b, miR-17, and PTEN in IMN, the correlations between PTEN protein and miR-106a, miR-19b, miR-17; between serum PTEN and Alb, Urea, Crea, Cysc, eGFR, 24 h-UP were analyzed in the current paper. The results showed that PTEN was negatively correlated with miR-106a, and miR-19b, serum Urea, Crea, Cysc, and 24 h-UP were positively correlated with PTEN, serum Alb and eGFR were
negatively correlated with PTEN. As measured by the correlation coefficient, the correlation between serum Cysc and PTEN was the strongest, followed by that between serum Alb, eGFR, and PTEN. These results suggest that early decrease in glomerular filtration function maybe related to PTEN, miR-106a, and miR-19b. MiR-106a and miR-19b maybe the upstream molecules of PTEN, which are involved in the pathogenesis of IMN through regulation of the expression of PTEN gene, whereas the pathogenetic role of miR-17 in IMN is independent of PTEN.

In summary, in this study we propose new noninvasive biomarkers for diagnosis of IMN and speculate on the possible pathogenic mechanisms in IMN; this will provide a theoretical basis for an in-depth exploration of the pathogenesis of IMN. However, our study has some limitations. Further experiments are needed to explore the specific pathways by which miR-106a, miR-19b, and PTEN promote apoptosis of podocytes, as well as the role of miR-17 in the pathogenesis of IMN. Moreover, as there was no disease control group in this study, the differential diagnostic value of miR-106a, miR-19b, miR-17, and PTEN in IMN remains to be elucidated.

CONFLICT OF INTEREST
There is no conflict of interest in this work.
