ABSTRACT

Introduction  Behavioural interventions in early life appear to show some effect in reducing childhood overweight and obesity. However, uncertainty remains regarding their overall effectiveness, and whether effectiveness differs among key subgroups. These evidence gaps have prompted an increase in very early childhood obesity prevention trials worldwide. Combining the individual participant data (IPD) from these trials will enhance statistical power to determine overall effectiveness and enable examination of individual and trial-level subgroups. We present a protocol for a systematic review with IPD meta-analysis to evaluate the effectiveness of obesity prevention interventions commencing antenatally or in the first year after birth, and to explore whether there are differential effects among key subgroups.

Methods and analysis  Systematic searches of Medline, Embase, Cochrane Central Register of Controlled Trials, Cumulative Index to Nursing and Allied Health Literature (CINAHLL), PsyInfo and trial registries for all ongoing and completed randomised controlled trials evaluating behavioural interventions for the prevention of early childhood obesity have been completed up to March 2021 and will be updated annually to include additional trials. Eligible trialists will be asked to share their IPD; if unavailable, aggregate data will be used where possible. An IPD meta-analysis and a nested prospective meta-analysis will be performed using methodologies recommended by the Cochrane Collaboration. The primary outcome will be body mass index z-score at age 24±6 months using WHO Growth Standards, and effect differences will be explored among prespecified individual and trial-level subgroups. Secondary outcomes include other child weight-related measures, infant feeding, dietary intake, physical activity, sedentary behaviours, sleep, parenting measures and adverse events.

Ethics and dissemination  Approved by The University of Sydney Human Research Ethics Committee (2020/273) and Flinders University Social and Behavioural Research Ethics Committee (HREC CIA2133-1). Results will be
INTRODUCTION

Childhood obesity is one of the most serious public health issues of the 21st century, and requires urgent action. Globally, an estimated 38 million (6%) children aged under 5 years were living with overweight or obesity in 2019, and prevalence is increasing across every continent as environments become more obesity conducive. While childhood obesity affects all sections of society, it disproportionately affects racial and ethnic minority groups and populations with a lower socioeconomic position (SEP), and thus is also a major health equity issue. Children with obesity are much more likely to have obesity across the lifecycle, and are at increased risk of short-term and long-term negative health sequelae, such as poor mental and musculoskeletal health, type 2 diabetes, asthma and cardiovascular disease. This places a large burden on healthcare systems, and has significant economic consequences arising from increased disability and decreased productivity and life expectancy. Thus, identifying modifiable behaviours for the early prevention of childhood obesity is critical to inform the development of early intervention strategies.

There are a variety of modifiable behaviours that may influence energy balance and therefore may be implicated in childhood obesity prevention, namely, feeding practices, dietary intake, physical activity, sedentary behaviours and sleep. For instance, appropriate responsive feeding has been identified as promising for obesity prevention, while consumption of sugar-sweetened beverages is associated with severe obesity in children aged less than 5 years. Data are mixed on the protective benefits of breast feeding for the prevention of obesity, though some studies suggest that longer duration of exclusive breast feeding may provide modest protection. Similarly, there may be an association between age at introduction of solids and growth, with mixed results surrounding the direction of this association and the underlying causal mechanisms. Previous systematic reviews have reported significant inverse associations between physical activity and measures of adiposity in children. Conversely, sedentary behaviours such as television viewing or screen time are associated with higher body mass index (BMI) levels and greater adiposity in young children. There is now also a large body of observational evidence supporting the relationship between short sleep duration and an increased risk of obesity across all age groups, including infants and young children, though a recent systematic review found inconsistent evidence of an association between shorter infant sleep duration and healthier body composition up to age 24 months.

In addition to these behaviours, individual-level covariates known or hypothesised to be predictive for childhood obesity include prepregnancy maternal and paternal BMI, age, race, ethnicity, SEP, excess gestational weight gain, parity, smoking during pregnancy, gestational diabetes, birth mode of delivery (cesarean, vaginal), birth weight, gestational age at birth, baby’s sex, intrapartum antibiotic prophylaxis and childcare attendance. Some of these covariates may also be individual-level effect modifiers, predicting how effective an intervention is likely to be, for example, SEP and race/ethnicity. Trial-level characteristics such as timing of intervention onset, setting and the level of well-child healthcare available in the community may also modify intervention effectiveness.

Limitations and evidence gaps identified in previous reviews

In the past 5 years, there have been numerous reviews of childhood obesity prevention trials encompassing a variety of intervention types, settings and age groups. Few of these focused solely on infancy, and many spanned multiple life stages from the prenatal period to 18 years of age. One review found that family-based childhood obesity prevention interventions most frequently targeted children 2–10 years of age (78%), with fewer targeting infants aged 0–1 year (24%) or the prenatal period (8%). Most reviews highlighted the urgent need for further rigorous evidence to inform obesity prevention interventions in the very early childhood years. Given the consequences of rapid early life weight gain, associated epigenetic changes and early onset of obesity in many children, there is strong rationale to start preventive interventions early when biology is most amenable to change, and before negative obesity-conducive behavioural patterns are established.

Most of the childhood obesity prevention reviews to date have used qualitative methodology such as narrative reviews, content analysis and systematic reviews without meta-analysis to describe variations in study design, setting, population, interventions and outcomes, and to
hypothesise that certain individual and trial-level characteristics may enhance effectiveness via proposed conceptual frameworks and intervention models. 14 40 42–46 Yet, quantitative evaluation is required to formally test these hypotheses. Recently, Brown et al41 updated a Cochrane systematic review and aggregate data meta-analysis on obesity prevention in children aged 0–18 years, and found that interventions focusing on diet and physical activity combined can lead to a small reduction in BMI z-score in children aged 0–5 years of age (mean difference −0.07, 95% CI −0.14 to −0.01). However, a huge variety in intervention approaches limited their ability to conduct meaningful comparisons, and many multicomponent interventions were originally reported as a whole package, precluding evaluation of discrete intervention characteristics. Moreover, the aggregated data were insufficient to derive conclusions on effect differences by individual-level characteristics such as ethnicity and SEP.

The Early Prevention of Obesity in Children (EPOCH) Collaboration conducted a world-first individual participant data (IPD) prospective meta-analysis (PMA) of four randomised controlled trials (RCTs) of behavioural interventions for the prevention of early childhood obesity.39 They found that, compared with usual care, early childhood interventions were modestly effective in reducing BMI z-score 18–24 months after birth by 0.12 SD (which translates to a 2% decrease in obesity prevalence). However, when accounting for missing data this difference was no longer significant. There was some heterogeneity across trials, and interventions appeared to be more effective in populations with limited publicly funded existing healthcare programmes, in this instance defined as a maximum of one postnatal home visit.39 However, this finding needs to be confirmed in analyses including more than four studies. EPOCH’s predictive analyses of individual and trial-level factors did not have sufficient power to detect reliable differences in BMI z-score. Thus, the overall effectiveness of early obesity prevention interventions remains uncertain, as does whether there may be differential effects among subgroups.

Need for IPD meta-analysis

The limitations and evidence gaps described above highlight the need for more powerful and in-depth analyses focusing on preventive interventions in very early childhood. Since the EPOCH PMA,39 we have identified more than 60 additional ongoing or completed very early obesity prevention trials worldwide with a combined sample size of more than 50 000 participants. While most trials are powered to detect some important differences in key outcomes, individually they have limited power to detect a difference in our primary outcome, BMI z-score at 24±6 months of age. In order to reliably detect a reduction in BMI z-score similar to that seen in EPOCH (−0.12),39 2920 participants are required (90% power, 2-sided 5% level of significance). Moreover, usually about four times that sample size (n~12 000) is required to detect differences in subgroups.49 The expected total sample size for Transforming Obesity Prevention for CHILDren (TOPCHILD) will exceed these estimates (as by July 2021, 45 trials including 40 030 eligible participants have already agreed to share their IPD).

Conducting a trial of this size would be time and resource intensive. A more efficient method is to combine IPD from trials in a pooled analysis to increase the sample size and therefore statistical power. This strengthens the chance of detecting intervention effect differences, and enables us to determine the size of such effects with greater certainty,50 while also allowing variation in study designs and population which heightens generalisability and allows a greater diversity to study effect modification for different subgroups of individuals or trial characteristics.51 Moreover, this collaborative approach maximises the use of existing data, thereby reducing research waste.

Thus, we will conduct an IPD meta-analysis with detailed subgroup analyses of all available trials to confirm whether early obesity prevention interventions commencing antenatally or in the first year after birth are effective, and whether effectiveness varies across subgroups defined by individual-level or trial-level characteristics. The knowledge generated from this study can be used to inform decision-making around the design and implementation of more effective, efficient, equitable and targeted interventions for the prevention of childhood obesity and its sequelae.

Objectives

This IPD meta-analysis will address the following research questions:

1. Compared with usual care, no intervention or attentional control, what are the effects of parent/caregiver-focused behavioural obesity prevention interventions commencing during pregnancy or infancy on:
   a. child BMI z-score at age 24 months (±6 months)? (primary outcome),
   b. child BMI z-score at alternative timepoints, other child weight-related measures, infant feeding, dietary intake, physical activity, sedentary behaviours, sleep, parenting measures and adverse events? (secondary outcomes),

2. Do intervention effects vary across individual-level characteristics (eg, parental BMI, parity, SEP, birth weight)?

3. Do intervention effects vary across trial-level characteristics (eg, access to existing well-child healthcare programmes, intervention mode of delivery, timing of intervention onset)?

METHODS AND ANALYSIS

We will conduct a systematic review with IPD meta-analysis and a nested PMA according to the methods recommended by the Cochrane Collaboration.52 53 A nested PMA enables integration of prospective evidence into a retrospective meta-analysis, and harmonisation among planned/ongoing studies.53 Lead investigators of eligible
Eligibility criteria

Types of studies

This systematic review will include RCTs only, including feasibility studies, pilot trials and definitive trials. Randomisation may occur at the individual level or by cluster (eg, child care, community), including stepped-wedge designs. Quasi-randomised trials are excluded as they may introduce bias. There are no language or date restrictions.

Trial participants

Participants will be parents/caregivers (including pregnant women) and their infant(s) aged 0–12 months (at baseline). Caregiver is defined as the person with primary responsibility for care of the child, and excludes secondary sources of support, such as child care providers and early childhood teachers. Women may be primipara or multipara, and both singletons and multiples are eligible.

Types of interventions

Interventions must be behavioural interventions targeting parents/caregivers, and include at least one component related to modifiable child behaviours that may influence overweight/obesity risk (eg, infant feeding, dietary intake, physical activity, sedentary behaviours, sleep). They may commence in the preconception or antenatal phase but must include intervention exposure targeting the birth to 12 months infancy stage, as pregnancy-only interventions are considered distinct and are currently being examined by Dodd et al in a separate IPD meta-analysis. Only childhood obesity prevention-focused trials will be included; these are defined as trials that clearly state childhood obesity prevention as a key aim/objective. Interventions focused only on improving an obesity-related behaviour (eg, sleep, delayed introduction of solid foods), as well as those focused on treatment of obesity, stunting or underweight will be excluded. Trials with a dual focus to prevent obesity and undernutrition are eligible, though we will carefully consider and prespecify how their data will be incorporated in the statistical analysis plan. Interventions focused solely on nutritional supplements will be excluded, as they are not considered to be behavioural interventions.

Types of comparator/control

Eligible trials must have either (1) a usual care control arm, defined as existing local child healthcare, or (2) no intervention (including waitlist control) or (3) attention control (eg, child safety education).

Types of outcome measures

To be included, trials must collect at least one of the child weight-related outcomes listed in table 1 post intervention (at any age), that is, BMI/BMI z-score, prevalence of overweight/obesity, per cent fat content/adiposity, skinfold thickness, abdominal circumference, waist-to-height ratio. This is considered a legitimate and pragmatic approach given our review is of multicomponent public health interventions focusing on obesity.

Eligibility for nested PMA

In accordance with PMA methodology, only planned/ongoing trials will be eligible for the nested PMA if trial results were not yet known to the investigator/s at the time the main components of the TOPCHILD protocol (ie, aims and objectives, hypotheses, eligibility criteria, main outcomes, subgroup and sensitivity analyses) were initially agreed in December 2020. We encourage investigators of planned/ongoing trials to collect the outcomes and subgroup variables listed in table 1 where possible, to facilitate data harmonisation and synthesis.

Information sources and search strategy

In March 2020, we undertook an initial systematic search for eligible trials using the following databases from their inception: Medline (Ovid), Embase (Ovid), Cochrane Central Register of Controlled Trials, CINAHL (EBSCO), PsycInfo, ClinicalTrials.gov and the WHO’s International Clinical Trials Registry Platform’s Search Portal. The full search strategy is available in online supplemental appendix 2. This search will be updated annually for the duration of the TOPCHILD Collaboration (currently funded until end 2023). Collaborators and contacts will also be asked to notify us of any planned, ongoing or completed trials of which they are aware that may meet the eligibility criteria.

Selection of studies for inclusion in the review

Two members of the TOPCHILD Steering Group will independently screen all retrieved records against eligibility criteria. Any discrepancies will be resolved by discussion or, if required, adjudication by a third reviewer from the Steering Group. The Principal Investigator and/or corresponding author of eligible trials will be invited by email to join the TOPCHILD Collaboration. If there is no response to initial emails and reminders, we will contact co-authors and/or other contacts listed in registration records and consult our existing networks to see if they can reach out to those they may know. If IPD cannot be obtained for an eligible trial, we will use aggregate data sourced from publications where available.

Online supplemental appendix 3 lists eligible trials identified up to March 2021.

Data collection, management and confidentiality

Data receipt/extraction

Trialists of all eligible studies will be invited to share deidentified IPD via secure data transfer platforms or via an institutional-secure email using password-protected zip files. Data will be provided according to a prespecified coding template where possible. Otherwise, data will be accepted in any format and recoded as necessary. The
Table 1  Outcomes and subgroups

| Variable                          | Definition/explanatory text/examples* |
|-----------------------------------|---------------------------------------|
| **Primary outcome**               |                                       |
| BMI z-score at age 24 months (±6 months) | Determined in accordance with WHO growth standards |
| **Secondary outcomes**            |                                       |
| BMI z-score at 12 months (±3 months) | Determined in accordance with WHO growth standards |
| BMI z-score at 48 months (±12 months) | Determined in accordance with WHO growth standards |
| BMI z-score beyond 60 months      | Determined in accordance with WHO growth standards |
| **Other weight-related measures** |                                       |
| Infant feeding                    | For example, prevalence of overweight/obesity (defined as BMI z-score of at least 2 SD above the WHO reference), per cent fat content/ adiposity, skinfold thickness, abdominal circumference, waist-to-height ratio, velocity of weight gain, weight-for-length, per cent excess BMI >95th percentile, adiposity rebound |
| **Dietary intake**                | For example, energy intake, intake of fruit, vegetables, energy dense nutrient poor foods, and sugar-sweetened beverages |
| **Sedentary behaviours**          | For example, screen time, restrained time while awake (in prams/strollers, high-chairs, strapped on a caregiver’s back or chest) |
| **Physical activity**             | For example, active play duration, prone play (“tummy time”), device assessed physical activity time |
| **Sleep**                         | For example, sleep duration, measures of sleep quality such as frequency and duration of waking at night |
| **Parental/caregiver measures**   | General and domain-specific parenting styles and practices, for example, parenting self-efficacy, parenting styles, parent feeding practices, parent physical activity practices, parent sleep practices, stress |
| **Adverse events**                | For example, underweight, injuries, infection |
| **Individual-level subgroups**    |                                       |
| Socioeconomic position            | For example, household income/country median household income, parent/caregiver highest education level, employment status |
| Parental weight status            | For example, maternal prepregnancy BMI, paternal BMI |
| Race/ethnicity                    | Trialist defined |
| Maternal age                      | At recruitment |
| Maternal gestational weight gain   | In kilograms |
| Parity                            | Primipara, multiparous |
| Mode of delivery at birth         | Caesarean, vaginal |
| Birth weight                      | In grams |
| Weight for gestational age         | Small for gestational age, appropriate for gestational age, large for gestational age |
| Sex                               | Female, male, uncertain/other |
| Gestational age at birth          | Preterm, term |
| Household composition             | For example, 2 versus 1 adult household, siblings, marital status |
| Type of pregnancy                 | Singleton, multiple |
| Maternal diabetes                 | Gestational, type 1, type 2 |
| Smoking during pregnancy           | yes/no |
| Infant’s age at enrolment         | In months |
| Child’s age at final assessment    | In months |
| Child care attendance              | yes/no |
| **Trial-level subgroups**         |                                       |
| Delivery mode (intervention)      | For example, face-to-face, letter, mobile digital device, individual versus group |
| Intervention setting              | For example, household residence, community healthcare facility |

Continued
TOPCHILD Collaboration database. Data from each trial will be checked with respect to sequence generation, allocation concealment, geographical location, sample size, outcome measures and definitions will be extracted into a database and cross-checked against any published reports, trial protocols, registration records and data collection sheets.

Data processing
Data from each trial will be checked with respect to range, internal consistency, consistency with published reports and missing items. Integrity of the randomisation process will be examined by reviewing the chronological randomisation sequence and pattern of assignment, as well as the balance of participant characteristics across intervention and control groups. Any inconsistencies or missing data will be discussed with trialists and/or data managers and resolved by consensus. Once finalised, data from each of the trials will be combined into a single TOPCHILD Collaboration database.

Risk of bias assessment and certainty of evidence appraisal
Included studies will be assessed for risk of bias by two independent reviewers from the TOPCHILD Steering Group using Version 2 of the Cochrane risk-of-bias tool for randomised trials (RoB 2). This tool includes five domains encompassing bias arising from: the randomisation process, deviations from intended interventions, missing outcome data, measurement of the outcome and selection of the reported result. For cluster-randomised trials, bias arising from identification or recruitment of individual participants within clusters will also be assessed. The certainty of evidence will be assessed according to Cochrane procedures using the Grading of Recommendations Assessment, Development and Evaluation approach. Any differences will be resolved by consensus or with a third reviewer from the TOPCHILD Steering Group.

Primary outcome
The primary outcome will be BMI z-score at age 24 months (±6 months), determined in accordance with WHO growth standards. We selected BMI z-score, over other measures such as weight-for-length, in light of accumulating evidence that it is more highly correlated with weight status in infancy and is better at predicting future obesity risk. In addition, WHO BMI for age charts are applicable to all infants/children regardless of SEP or ethnicity, which aligns with the global nature of the TOPCHILD Collaboration.

Secondary outcomes
All outcomes are detailed in table 1. Where possible, definitions will be standardised, otherwise outcomes will be used as defined within each trial. Secondary outcomes include BMI z-score at other timepoints, other measures of child weight, infant feeding (including breast feeding and introduction of solid foods), dietary intake, sedentary behaviours, physical activity and sleep, as well as parent/caregiver-related measures. We will also assess any adverse events, such as underweight or poor weight gain.

Subgroups
All included subgroups are listed in table 1. Individual-level and trial-level subgroup analyses will be conducted for the primary outcome of BMI z-score at age 24 months (±6 months). Those of primary interest at the individual level include SEP, race/ethnicity, prepregnancy maternal/paternal BMI, maternal age, gestational weight gain and...
parity, and at the trial level include timing of intervention onset, current level of background care in the commu-
nity, recruitment country and mode of delivery.

Where possible, outcomes and subgroups will be
collected as continuous variables to maximise power to
detect intervention effects and interactions, and enable
exploration of any non-linear relationships. Dichoto-
mous and categorical variables will also be collected to aid
interpretation, and if data are insufficient for the prespec-
ified subgroup analyses, categories will be collapsed prior
to any analyses being conducted.

Data analysis
A detailed statistical analysis plan will be prepared and
agreed on by the TOPCHILD Collaboration members
prior to any analyses being undertaken. Analyses will
follow the intention-to-treat principle and include all
randomised infant–parent/caregiver dyads for which
data are available (including any that were excluded from
the original study analysis). For cluster RCTs, correlated
data will be taken into account by fitting the models using
generalised estimating equations to derive appropriate
standard errors. Correlations between multiples also will
be accounted for in the analyses.

The primary analysis for all outcomes will be conducted
using a one-stage approach combining all available IPD
and aggregate data (where IPD are unavailable) to
reduce the risk of availability bias. The combined
dataset will be analysed including trial as a random effect.
Models will be chosen appropriate to the outcome type.
Generalised linear models with appropriate distributions
and link functions will be used for continuous and binary
outcomes, while Cox proportional hazards regression
will be used to analyse time-to-event outcomes subject to
censoring. For example, linear models will be used for the
primary outcome while relative risk binomial regression
with log link function will be used for prevalence of over-
weight/obesity, and Cox models will be used for breast
feeding duration. Where possible, continuous outcomes
and subgroup variables will be analysed on their contin-
uous scale to maximise utility of available data.

Heterogeneity of intervention effects across trials will
be investigated using quantitative measures (I²) supple-
mented by graphical presentations as recommended in
the Cochrane Handbook. Any notable heterogeneity
identified will be explored further to ascertain if the
combination of trials is appropriate.

Results will be reported using appropriate estimates
of intervention effect (relative risks, mean differences
or hazard ratios) with 95% CIs and associated two-sided
p values. For trials with multiple intervention arms, we
will present the data for each intervention arm compared
with the control arm, with the number of participants in
the control arm adjusted to ensure no double counting. Missing
data will be explored in sensitivity analyses using
appropriate methods. All analyses will be performed
using the open-source software R.

Differences in intervention effect between the prespec-
ified subgroups will be examined by testing a treatment
by subgroup interaction term within the 1-stage-model.
Findings of subgroup analyses will be reported as exploratory,
and summarised using a 1-stage-approach supplemented by graphical presentation in a forest plot
using a 2-stage-approach. Non-linear relationships will
be explored for continuous subgroup variables using a
multivariate meta-analysis of the trend.

Other exploratory analyses for the primary outcome
will include graphical presentation of BMI z-score distri-
butions to investigate any differences beyond mean differ-
ences and examine any non-linear relationships. The
potential for mediation and moderator analyses using
parent/caregiver measures will be explored and detailed
in a statistical analysis plan after we have extracted infor-
mation about relevant variables collected by included
trials.

Assessment of selection or publication bias
Potential selection bias and publication bias will be inves-
tigated by conducting a nested PMA and comparing
prospectively versus retrospectively included trials in a
sensitivity analysis. We will also seek to include any unre-
ported outcomes sourced from each trial’s IPD, which
may alleviate selective outcome reporting bias. Lastly,
contour-enhanced funnel plots will be used to examine
whether there are differences in results between more
and less precise studies.

Adjustments for multiple testing
Only one primary outcome was selected for this study
(table 1). For secondary outcomes and subgroup anal-
yses, no formal adjustments will be made for the poten-
tial inflation of type 1 error rates due to multiple testing.
Instead, we will follow Schulz and Grimes’ approach
and recommendations of the Cochrane Collaboration.
This involves cautious interpretation of the magnitudes
of effect, patterns and consistency of results across related
outcomes and clinical/biological plausibility rather than
focusing on any single statistically significant result in
isolation which can be extremely misleading.

Planned sensitivity analyses
Where possible, the following sensitivity analyses will be
conducted for the primary outcome:

► Two stage approach.
► Including IPD only, that is, excluding trials without
IPD available.
► Including prospectively included trials only (nested
PMA), that is, planned/ongoing trials for which results
were not yet known to investigator/s at the time the
main components of the TOPCHILD protocol were
agreed.
► Adjusting for birth weight as a covariate.
► Excluding trials with a high risk of bias for sequence
generation and/or allocation concealment and/or
loss to follow-up.
► Excluding trials with a significant conflict of interest (eg, funded by industry).
► The impact of missing data on conclusions about the intervention effect (if appropriate).

Project management
Membership of the TOPCHILD Collaboration includes trial representatives from each of the trials contributing IPD to the project, a Steering Group and an Advisory Group. Trial representatives have the opportunity to contribute their expert knowledge to the TOPCHILD Collaboration and provide input into the protocols, statistical analysis plan and final results manuscript. The Steering Group will be responsible for data collection, management and analysis, as well as communication within the Collaboration, including newsletter updates, maintenance of the TOPCHILD website and organisation of virtual or face-to-face collaborator meetings. The Advisory Group will comprise invited experts in childhood obesity prevention, IPD meta-analysis, statistics, behaviour change theory/methods and policy implementation.

ETHICS AND DISSEMINATION
Ethical considerations
IPD will be provided by each included trial on the stipulation that ethical approval has been provided by their respective Human Research Ethics Committees (or equivalent), and participants gave informed consent before enrolment to participate in the initial individual trials. Trialists remain the custodians of their own data, which will be deidentified before being shared with the TOPCHILD Collaboration. Ethical approval for this project has been granted by The University of Sydney Human Research Ethics Committee (2020/273) and Flinders University Social and Behavioural Research Ethics Committee (project no. HREC CIA2133-1).

Publication policy
TOPCHILD manuscripts will be prepared by the Steering Group in consultation with the Advisory Group, and circulated to the full Collaboration for comment, revision and approval prior to submission for publication. Any reports of the results of this study will be published either in the name of the collaborative group, or by representatives of the collaborative group on behalf of the TOPCHILD Collaboration, as agreed by members of the collaborative group.

DISCUSSION
This will be the largest IPD meta-analysis to date of trials evaluating behavioural obesity prevention interventions commencing in very early childhood. The findings will inform next generation obesity prevention initiatives that are effective, efficient and equitable. Such interventions could set children on a better health trajectory early on and reduce the potentially life-long burden of disease associated with obesity.

The main strengths of this study arise from use of IPD meta-analysis methodology, which is considered the ‘gold standard’.73 It involves collecting the raw line-by-line data for each participant in each study from the original trialists. This can improve the quality of data, and enables more in-depth and precise analyses than would be possible using only published aggregate data.52 In particular, IPD meta-analysis will enable thorough exploration of individual-level and trial-level subgroups, so that we may quantify any differential effects and uncover the key determinants of successful outcomes. This addresses the limitations identified in previous reviews of childhood obesity prevention,39 41 46 where such detailed and sufficiently powered analyses were simply not possible.

A potential limitation of this study is the risk of not obtaining IPD from all eligible studies, resulting in inclusion bias. Where available, we will include aggregate data from these studies, and conduct sensitivity analyses with inclusion of IPD only to explore potential bias.74 Further, there may be variations across studies in how measures are collected and reported, which may lead to some imprecision and difficulties pooling the data. We will seek to address this using nested PMA methodology, whereby researchers of planned or ongoing trials are encouraged to harmonise their trial design and collect core outcome measures to facilitate meta-analysis and interpretation.53 For completed studies, we will derive common outcome variables by cleaning, recoding and converting existing measures where possible.

We plan to complete the first round of study identification and IPD collection by early 2021, then conduct the primary analyses and disseminate the results by the end of 2022. Trials that are not completed in time to provide data for this cycle will remain a part of the TOPCHILD Collaboration, and their data will be included in future updates of TOPCHILD. Depending on data availability, we may consider collecting additional emerging variables of interest, such as intrapartum antibiotic prophylaxis and the microbiome, for future TOPCHILD cycles.

This IPD meta-analysis will be conducted in parallel with a complementary TOPCHILD project (Johnson et al25 unpublished), which aims to deconstruct childhood obesity interventions into their components (ie, delivery features, target behaviours and behaviour change techniques) using systematic, internationally recognised frameworks and both published and unpublished trial materials. In future, the resulting dataset curated from these two projects will be used for predictive modelling of intervention component effectiveness at an individual participant level, facilitating a personalised or precision medicine approach to public health prevention.

The TOPCHILD Collaboration will maximise use of existing trial data that will enable us to understand and use the most effective intervention components for specific population groups and contexts. It will provide urgently needed evidence to inform development and...
implementation of effective, efficient and equitable interventions for the prevention of early childhood obesity. The results will be of prime importance for guideline developers, policy-makers, consumers and the research community. Further information and updates on the TOPCHILD Collaboration can be found at www.topchild.org

Acknowledgements The authors thank Slavica Berber for guidance on the search strategy, and Jonathan Williams for his project management support. We would also like to acknowledge the NHMRC Centre of Research Excellence in Early Prevention of Obesity in Childhood (EPOCH CRE), who supported the pilot and foundational work for this project. Lastly, we thank Maria Luisa Garmendia and Camila Corvalan for their feedback on an earlier version of this protocol.

Contributors ALS together with KEH, BJJ, LA, RG developed the research question and protocol registration. KEH wrote the first draft of the manuscript. KEH, BJJ, ALS, RG, LA developed the eligibility criteria and search strategy; KEH, MA, AB, BJJ, SL, ALS performed the search and screening. AH, CR, CTW, DE, DAO’C, IM, KPR, LAB, LPS, LMW, MS-S, PC, RT, SM, ST, WS provided critical review and feedback at each stage of the process. All authors critically revised the manuscript for intellectual content, and agreed and approved the final manuscript. KEH is the guarantor of the review.

Funding This work was supported by the Australian National Health and Medical Research Council (NHMRC) Ideas Grant TOPCHILD (Transforming Obesity Prevention for CHILdren); Looking into the black box of interventions (GNT1186363); Funders had no role in developing this protocol. Individual authors declare the following funding: ALT reports funding from NIH R01HD073237; AML reports funding from NIH National Center for Advancing Translational Science through grant # UL1TR000117 and UL1TR001998; BJT reports funding from Health Research Council of New Zealand; CGA reports funding from The PepsiCo Foundation; CP reports funding from National Institutes of Health, Robert Wood Johnson Foundation, World Health Organization, US Department of Agriculture; COS reports funding from University of Cincinnati University Research Council; DAO is supported by an Australian National Health and Medical Research Council (NHMRC) Translating Research into Practice Fellowship (APP1168749); EG reports the PROBIT study was supported by grant MOP-53155 from the Canadian Institutes of Health Research and grant R01 HD050758 from the US National Institutes of Health; IMP reports funding from grant R01DK088244 from the United States National Institute of Diabetes and Digestive and Kidney Diseases; JCB reports funding from US Department of Agriculture; JKL and LTK reports funding from Fonds NutsOhra awarded (100.939); JSS reports funding from NIH NIDDK, NIH NHLBI, PCORI; JL is an employee of USDA ARS and the Agency did fund the Delta Healthy Sprouts Trial (Project 6401-5300-003-00D); Kdlh reports funding from 1R01HD092483-01 (MPI: de la Haye, Salvy), NH/NIH/CHD; KDH is supported by an Australian Research Council Future Fellowship (FT130100637); LMW reports funding from NHMRC (#493112; #1003780; #1169823); LW is supported by a NHMRC Career Development and NHF Future Leader Fellowship; MB reports HAPPY was funded by a UK NIHR Programme Grant for Applied Research (project number RP-PG-0407-10044); MCR reports the Baby Act Trial was sponsored by the Center for Collaborative Research in Health Disparities under grant US5 MD007600 of the National Institute on Minority Health and Health Disparities from the National Institutes of Health; MJM reports funding from USDA AFRI 2011-68001-30207; NCB reports their original study was partly funded by the Norwegian Women’s Public Health Association, who had no influence on any part of the study design, implementation and evaluation; RKG is a Chief Investigator on the Early Prevention of Obesity in Childhood, NHMRC Centre for Research Excellence (1101575); RSG is supported by the National Institute of Food and Agriculture/US Department of Agriculture, award number 2011-68001-30207, and the National Institutes of Health/National Institute of Child Health and...
Human Development through a K23 Mentored Patient-Oriented Research Career Development Award (K23HD081077; principal investigator: Rachel S. Gross); RL reports funding from UK NPRi (National Prevention Research Initiative), MRC PHIND (Public Health Intervention Development programme); SLOR reports funding from European Unions Horizon 2020 Research and Innovation Programme (Grant Agreement no. 847384) and Australia National Health and Medical Research Council (NHMRC) (Grant application no. APP1194234); S-JS reports funding from NMHM US54MD000052 (MPI: Salvy & Dutton Project #2), NICHD R01HD092483 (MPI: Salvy & de la Haye); SA-F is a co-investigator on the current INSIGHT grant which follows participants to ages 6 and 9; NN 2611DK098244; AB-F reports the SPUDIN program in Guatemala is funded by the Inter-American Development Bank with donations of The Government of Japan and The PepsiCo Foundation.

**Competing interests** AB, ALS, BJJ, KEH, MA, RKG, SL and EPS reports grants from NHMRC Ideas Grant TOPCHILD (Transforming Obesity Prevention for CHILDren); APE and CGA reports grants administered by the Inter-American Development Bank from The Government of Japan and The PepsiCo Foundation; ALT reports grants from National Institute of Health; BJT reports grants from NZ Health Research Council; EO reports grants from the US National Institutes of Health, and the Canadian Institutes for Health Research; IMP reports grants from NIH/NIDDK, JJS reports grants from PCORI, NIH NIDDK and NHLBI, and personal fees from Danone Organic, American Academy of Pediatrics, and Lets Move Maine; LJK and JKL reports grants from Fonds NutsOhra; MCR reports grants from National Institute on Minority Health and Health Disparities National Institutes of Health Center for Collaborative Research in Health Disparities, and personal fees from Rhythm Pharmaceuticals; RSG reports grants from US Department of Agriculture and NIH/NICHD.

**Patient and public involvement statement** The TOPCHILD Collaboration involves a broad range of stakeholders including health professionals, policy-makers and trialists. In addition, the Advisory Group includes a parent representative and intervention facilitator/nurse. They have given input into and feedback on this protocol and will be involved in discussion and interpretation of results.

**Patient consent for publication** Not applicable.
