Abstract

Background

Psychological and behavioral correlates are considered important in the development and persistence of obesity in both adults and youth. This study aimed to identify such features in youth with severe obesity (BMI ≥ 120% of 95th percentile of sex-specific BMI-for-age) compared to those with overweight or non-severe obesity.

Methods

Youth with BMI ≥ 85th percentile were invited to participate in a prospective research registry where data was collected on attributes such as family characteristics, eating behaviors, dietary intake, physical activity, perception of health and mental well-being, and cardiometabolic parameters.

Results

In a racially/ethnically diverse cohort of 105 youth (65% female, median age 16.1 years, range 4.62-25.5), 51% had severe obesity. The body fat percent increased with the higher levels of obesity. There were no differences in the self-reported frequency of intake of sugar sweetened beverages or fresh produce across the weight categories. However, the participants with severe obesity reported higher levels of emotional eating and eating when bored (p=0.022), levels of stress (p =0.013), engaged in fewer sports or organized activities (p=0.044), and had suboptimal perception of health (p=0.053). Asthma, depression and obstructive sleep apnea were more frequently reported in youth with severe obesity. The presence of abnormal HDL, HOMA-IR, CRP and multiple cardiometabolic risk factors were more common among youth with severe obesity.
Conclusions

Youth with severe obesity have identifiable differences in psychosocial and behavioral attributes that can be used to develop targeted intervention strategies to improve their health.

Introduction

Obesity and severe obesity are prevalent in the United States and the rates continue to rise among children. Recent data from NHANES indicates that 18.5% (15.8- 21.3) of youth ages 2-19 years have obesity, defined as body mass index (BMI) 95th percentile a sex-specific BMI-for-age, and 5.6% (4.0- 7.6) have severe obesity, defined as BMI 120% of 95th percentile of sex-specific BMI-for-age. Severe obesity increased from 4.0 % in 1999-2000 to 6.0 % in 2015-16 and the highest prevalence is seen among adolescents ages 12-19 years at 7.7% (5.0-11.2) [1,2]. Severe obesity is disproportionately higher among minorities (Hispanics and Non-Hispanic Blacks), youth living in non-urban areas, and households headed by individuals with high school education or less [3]. Children and adolescents with severe obesity are at higher risk for abnormal cardiovascular risk factors including higher blood pressure, lipids, insulin resistance and diabetes [4-6]. Additionally, they are more likely to experience asthma [7], depression, anxiety, and poor psychological well-being [8]. There is a critical need to identify behaviorally-based interventions that will maximize health of youth with severe obesity [9-11]. Yet, few studies have identified psychosocial and behavioral factors for severe obesity [12] that could inform such strategies. This study aimed to examine the psychosocial, behavioral, and clinical correlates of severe obesity in a cohort of youth to identify the contextual and behavioral factors that differentiate
those with severe obesity compared to those with non-severe obesity and overweight.

Study Design and Participants

The POOL cohort, named for the various participating clinics, was a prospective and voluntary registry for youth with overweight and obesity, ages 2-25 years old recruited from weight management and primary care clinics at Boston Children’s Hospital (BCH) from 2012-2016. The eligibility criteria were a) BMI 85th percentile sex-specific BMI-for-age for those <18 years on CDC 2000 growth charts or 25 kg/m2 for those 18 years; b) English speaking; and c) residents of New England as determined by the zip code of residence. Patients intending to undergo bariatric surgery for weight loss underwent the baseline visit prior to the surgery. Exclusion criteria were a) significant cognitive, psychosocial or medical illness that limits the subject’s ability to provide assent and/or participate in the research procedures such as severe autism, developmental delay and/or other conditions as determined by the investigators and b) pregnancy or intention to become pregnant within the next year for females. Patients were recruited by flyers posted in the clinics, by mail, or during a clinical visit. The study protocol was approved by the Institutional Review Board at BCH.

Measures

Study visits were conducted in the Clinical and Translational Study Unit (CTSU) after an overnight fast. An average of two measurements of height (nearest 0.1 cm) and weight (nearest 0.1 kg) obtained using a fixed stadiometer and Tanita digital scale, respectively with no shoes worn and outer clothing removed were obtained. The BOD POD Gold Standard Body Composition Tracking System (COSMED, the Metabolic
Company, Rome, Italy), an air displacement plethysmograph (ADP) method that measures whole body densitometry was used to determine fat and fat free mass [13,14]. Three measurements of blood pressure were taken by auscultation in the seated position on the right arm after 3 minutes rest, and the average of the final two measurements were used. Physicians conducted Tanner staging by physical examination on participants ages 6 to 18 years [15]. Tanner stage 1 was considered prepubertal, and all others post-pubertal. Children < 6 years were assumed to be prepubertal and those >18 years post-pubertal.

Parents of participants 12 years and older participants completed a) sociodemographic questionnaire with questions on race, ethnicity, and education, b) family and medical history and c) questions adapted from the Youth Risk Behavior Questionnaire on diet, physical activity, sedentary behaviors, and attitudes about health.[16] Pediatric Quality of Life Inventory (PedsQL) was used to measure health-related quality of life (HRQOL). The PedsQL has developmentally appropriate modules that assess 4 generic core scales (Physical, Emotional, Social, and Work or School functioning). Scores were calculated for each scale as well as for psychosocial health, which is an average of the emotional, social and work/school functioning scores. The overall health is the average of physical and psychosocial health scores. Parents completed the parent proxy age specific modules for participants 12 years; whereas, older participants completed the age-specific self-report modules [17,18]. Participants 13 years completed items on the Three-Factor Eating Questionnaire (TFEQ-R18) to measure 3 aspects of eating behavior including cognitive restraint (CR), uncontrolled eating (UE), and emotional eating (EE)[19] and selected items from McKnight Risk Factor Survey to assess disordered eating, which included the following questions: “In the past 12 months, how often have you kept
eating and eating and felt like you could not stop?” and “In the past 12 months, how often did you eat more than usual when you were bored or upset?”[20]

Lab Assay Methods

Fasting blood samples were obtained for lipids, insulin, glucose and CRP-hs and tested within 24 hours. The tests assays were performed on Roche/Hitachi Cobas® c system analyzer using the following methods: 1) Triglycerides: lipoprotein lipase enzymatic test (CV range 0.7-2.0%); 2) HDL-C and Total Cholesterol: enzymatic colorimetric method (CV range: HDL-C: 0.5-1.5%; Total Cholesterol: 0.6-1.6%); 3) Low-density lipoprotein (LDL-C) cholesterol: Friedewald calculation (TC = HDL-C+LDL-C+VLDL-C where VLDL-C is defined as TG/5 in the fasting state); 4) Glucose: hexokinase enzymatic test (CV range 0.5-1.3%); 5) Insulin: electrochemiluminescence Immunoassay (ECLIA, CV range 1.1-4.9%); 6) CRP-hs: particle-enhanced immunological agglutination assay (CV range 0.6 -3.5%).

Analysis Methods

All analyses are cross-sectional. BMI was calculated as weight/height $^2$ (kg/m$^2$). The definition of clinical and laboratory parameters in the study is noted in Table 2. Descriptive statistics were calculated as the median and range for continuous variables and as proportions for categorical variables. Correlation between continuous measures was assessed using the Spearman coefficient. Proportions were compared among weight categories by Fisher’s exact test. Due to skewness, distributions of continuous variables were compared among the weight categories using the Jonckheere-Terpstra Test for Independent Samples. An analysis of covariance (ANCOVA) was conducted to control for age and sex when comparing metabolic risk factor variables across weight categories. Log-transformation was
performed for variables with significant departure from normality. A two-sided p-value <0.05 was considered statistically significant. All analyses were conducted with IBM SPSS Statistics for Windows, Version 23.0 (IBM Corp, Armonk, NY).

Results

Characteristics of the 105 children who met eligibility criteria and participated in the baseline assessment are shown in Table 1. Median age of participants was 16.1 years (65% females); participants were of diverse racial and ethnic backgrounds. About half the sample (51.4%) had severe obesity, while 29.5% had non-severe obesity, and 19.1% had overweight. There were no statistically significant differences in the sociodemographic variables by category of weight. Median BMI of the participants was 31.7 kg/m2 (range 18.1-63.6) and median total body fat of 37.6% (range 12.2-61.0). Median total body fat increased significantly across the weight categories, and correlated strongly with BMI (r = 0.76; p = <0.001). About half of participants were post-pubertal across each of the weight categories. There was a strong family history of obesity, with 75% of participants reporting maternal obesity. Participants with severe obesity had a number of comorbid conditions, with asthma (26.7%) being the most common, followed by depression and obstructive sleep apnea as compared to those with obesity or overweight. Amongst the less frequently self-reported conditions (data not shown), 1 participant had type 2 diabetes and 3 reported an eating disorder.

Among the dietary and eating behaviors, self-reported frequency of intake of specific food and drinks did not differ significantly across the weight categories (Table 4). However, among the subset of participants 13 years, eating when bored was more frequently reported among those with obesity compared to those with
overweight (p=0.022). There was no significant difference in the eating behavior scores on the TEFQ-R18 for CR and UE by weight category; however, median scores for EE increased with increasing weight category (11.1 vs. 16.7 vs. 33.3 respectively; p=0.026). Subjects with severe obesity were more likely to report playing no sports or organized activities compared to those without (47.2% vs. 35.5% vs. 15.8%, respectively; p=0.044). Sedentary activities such as watching TV and video games or being active for 30 minutes/day was similar across the weight categories.

The prevalence of abnormal levels of metabolic risk factors among all participants was high for lipids, CRP, HOMA, and insulin, whereas it was low for blood pressure and glucose (Table 3). Statistically significant differences in the distributions of these risk factors by weight category were observed for the HDL-C, HOMA, Insulin and CRP. In our sample, BMI showed no correlation with total cholesterol (r= -0.054; p=0.588), LDL (r= 0.078; p=0.432) or triglycerides (r= 0.161; p=0.102) but a moderate inverse correlation with HDL (r= -0.352; p<0.001). The greatest difference was observed for CRP; median CRP for those with severe obesity was 3-4 times higher than those with overweight or non-severe obesity, and exceeded the cutoff for elevated risk of CVD (3.4 mg/L). Participants with severe obesity also had a significantly greater median number of risk factors that remained after adjusting for age and gender.

Subjects with severe obesity were more likely to report having sub-optimal health habits and health status when compared to those without (27.5% vs.12.5% vs. 11.1%, respectively; p=0.19 and 62.5% vs.37.9% vs. 35.3%, respectively; p=0.053). They also reported higher median levels of stress (6.5 vs. 6.0 vs. 5.0, respectively; p=0.035). Although most quality of life measures were lower in both the severely
obese and obese, there were no statistically significant differences or consistent trends by weight category.

Discussion

In this cross-sectional, clinic-based cohort of youth with overweight and obesity, there were expected increases % total body fat with increasing classes of obesity. While the individuals with severe obesity were slightly older, the differences were not statistically significant. Similarly, youth with severe obesity had a higher prevalence of co-morbidities and including, asthma, OSA, depression, presence of multiple cardiometabolic risk factors, low HDL, elevated HOMA and elevated CRP. Psychosocial and behavioral phenotypic differences were most compelling and possibly interrelated, including higher rates of emotional eating, eating when bored and perceived stress with increasing severity of obesity, and lower participation in organized sports as well as less maternal education. Understanding the underlying biology and interrelationships between these psychosocial and behavioral factors may help us to develop more effective prevention and treatment interventions to improve the health of youth with severe obesity.

The adverse levels of HDL-C, CRP and HOMA in individuals with severe obesity are consistent with findings from other studies. Lower levels of HDL-C have been identified in youth with severe obesity from population-based NHANES data at younger ages prior to identifiable differences in other lipid parameters [5]. Elevated levels of CRP, considered a marker of inflammation that has been associated with obesity in adults [21], and is thought to herald the onset of cardiometabolic consequences, such as coronary heart disease [22], hypertension [23,24], metabolic syndrome [25,26] and diabetes [27] is significantly higher in the youth with severe
obesity compared to those with non-severe obesity. While such levels have been previously identified in adults, a similar association has not been well defined in children [21]. The presence of elevated CRP and HOMA in youth with severe obesity adds to the growing body of evidence that supports an urgent call for intervention to prevent the potential oncoming wave of cardiometabolic disease in future generations.

Similar to other studies, there was a higher proportion of asthma, depression and obstructive sleep apnea in individuals with severe obesity. In a systematic review, Papoustakis et al noted the association of asthma in 30 out of the 31 cross-sectional studies and 12 out of the 13 prospective studies of individuals with obesity [28]. While the exact mechanism of this association remains to be elucidated, proposed mechanisms include systemic inflammation and mechanical effect, both due to expansion of the adipose tissue. There may also be a contribution of insulin resistance and a role of intestinal microbial dysbiosis causing higher lipopolysaccharides or other inflammatory agents [29,30]. The association of depression with severe obesity has also been described, albeit without a clear directionality. One representative study of adolescents with obesity found that after adjusting for demographics and emotional eating, the odds of having severe obesity versus obesity were 3.5 times higher for patients with depression (as measured by PHQ-9; a score 11 was considered depression) compared with those without (OR = 3.5; 95% CI 1.2,20.9, p = 0.030) [31]. Similarly, the odds of having severe obesity were also higher with anxiety (Generalized Anxiety Disorder Scale 10), OR = 4.93, 95% CI = 1.17,20.85, p = 0.030). In this study, there was no association of either depression or anxiety with emotional eating, but other studies have found emotional eating as a mediator for obesity in individuals with depression [32,33]. It is also
postulated that the presence of depression elicits response from the hypothalamic adrenal axis that leads to inflammatory milieu leading to obesity [34]. Notably, this study found that emotional eating and eating when bored was increased in individuals with severe obesity. A body of literature demonstrates the association of emotional dysregulation with weight gain and obesity [12,31,35,36]. It has been suggested in adults, that a poor emotional regulation may entail the use of maladaptive strategies to manage emotions and stress, for example, by using highly palatable and energy dense food to suppress emotions [37]. Studies in children have demonstrated that emotional eating is often followed by negative emotions [38–41], and is likely to be a learned behavior [42,43]. College students endorsed boredom as the emotion that most commonly triggers eating [44] that was replicated in the laboratory where the completion of a boring task was associated with snacking desire [45]. Assessment of subtypes of emotional eating in a cohort of 189 adults showed eating in response to depression (EE-D), anxiety/anger (EE-A) and boredom (EE-B) related to poorer psychological well-being, greater symptoms of eating disorder and more difficulties with emotional regulation [46]. It is also possible that the association of depression and severe obesity is mediated by emotional eating as demonstrated in college students in Mexico City [32] and Netherlands [33]. Findings highlight the importance of building skills for emotional regulation for children and adolescents with severe obesity [47]. Findings for emotional eating could also be explained by experiences of weight stigma (e.g. weight related teasing) that is more likely to be experienced by youth with severe obesity [48]. This study highlights the role of stress experienced by youth with obesity, that is increasingly being recognized to have a complex, perhaps bidirectional, relationship
Studies of hair cortisol concentration, thought to be deposited over longer periods of time, both in adults [50,51] and in children [52] have been shown to have high associations with obesity. Whether this relationship is linked to biological factors such as higher levels of circulating glucocorticoids or higher response to circulating glucocorticoids that predispose individuals to weight gain, or changes in internal milieu, such as imbalances in glucose homeostasis, is not clear. On the other hand, the higher levels of weight stigma carried by individuals with obesity, mental health issues (e.g. depression, anxiety etc), or physical disorders (e.g. asthma, OSA) can lead to chronic stress and/or higher circulating corticosteroids, making it a vicious cycle. The presence of higher levels of co-morbidities that can lead to increased levels of biological stress as well as the higher perceived levels of stress in this study, emphasize the role of both recognition and management of stress in youth with obesity.

Participants with severe obesity exhibited a reduced number of organized physical activities. It is not known whether the inactivity preceded the severe obesity or is a consequence of potential reduction in the agility of the body by excessive weight. However, there is evidence in the literature that lack of physical activity may be linked to the state of emotional dysregulation known to be associated with obesity [8,46]. Emerging evidence emphasizing the positive role of team sport participation on longer term mental health, especially in children who have experienced adverse childhood events [53] makes this an important consideration in youth such as those in this study. This study found no statistically significant differences in the dietary intake of foods shown to be related to risk of obesity including the servings of water, sugar sweetened beverages, fruits and vegetables, as well as the patterns of meals eaten at home and fast food intake. The lack of differences may be due to the
source of the sample, as participants were attending weight management programs and following treatment recommendations provided those programs. This study is limited by its cross-sectional design as well as recruitment in tertiary care weight management programs that may limit the generalizability of some of the findings. While a thorough assessment of body composition and cardiometabolic risk factors was done, the measurement of dietary intake was limited to self-reported frequency of selected food groups and physical activities. Further, the small sample size limits the comparison across gender and race/ethnicity groups. However, the comprehensive assessment in the study has provided the opportunity to identify important psychosocial, behavioral and clinical correlates that may play a role in the more effective management of obesity in such a population. This study is one of the few studies that has tried to comprehensively characterize differences in physiological, psychosocial and behavioral phenotypes in adolescents with severe obesity. The higher prevalence of psychological and behavioral phenotypes in this sample suggests that there are modifiable and possibly related targets of intervention. It also re-emphasizes the need for a multi-disciplinary team including clinician, behavioral psychologist, social worker and exercise physiologist to identify and address multitude of complex problems in these patients. Future larger and longitudinal studies are needed to tease out the causal pathways and interactions between these important modifiable targets of intervention.

**Declarations**

Ethics approval and consent to participate: This study was approved by the Institutional Review Board at Boston Children’s Hospital. Informed consent was obtained from a parent or legal guardian for minors < 18 years or from adult
participants and a written assent from youth ages 8 -17 years.

Consent for publication: Not applicable

Availability of data and material: The datasets generated and/or analysed during the current study are not publicly available due to IRB restrictions for sharing individual level data but are available from the corresponding author on reasonable request.

Competing interests: none

Funding: The Pool registry was funded in part by Milton Fund, New Balance Foundation Obesity Prevention Center, and Boston Children’s Hospital. VVT is partly supported by NIH-NIDDK K23 DK 110539.

Authors' contributions: SKO and TKR designed the study and the acquisition of the patient materials. SDdeF and KRS contributed to the study design and patient recruitment. JKC and VVT participated in patient recruitment and data acquisition. HAF and SKO analyzed the data. All authors participated in manuscript preparation and reviewed the version as submitted.

## Tables

### Table 1: Sociodemographic and Clinical Characteristics of Study Participants

(N=105) Overall and According to Weight Category

| Characteristic                          | n* | All                           | W                           |
|-----------------------------------------|----|-------------------------------|-----------------------------|
|                                         |    | Overall                       | Weight Category             |
| Age; median (min, max)                  | 105| 16.07 (4.62, 25.54)           | 14.40 (4.62, 22.99)         |
| Age Group; n, %                         |    |                               |                             |
| · Under 13 years                        | 32 | (30.5%)                       | 6 (30.0%)                   |
| · 13 years or older                     | 73 | (69.5%)                       | 14 (70.0%)                  |
| Gender; n, %                            |    |                               |                             |
| · Male                                  | 41 | (39.0%)                       | 7 (35.0%)                   |
| · Female                                | 64 | (69.0%)                       | 13 (65.0%)                  |
| Race; n, %                              |    |                               |                             |
| · Caucasian                             | 34 | (34%)                         | 6 (33.3%)                   |
| · African-American                      | 44 | (44%)                         | 6 (33.3%)                   |
| · Multiple Races/Other                  | 22 | (22%)                         | 6 (33.3%)                   |
| Ethnicity; n, %                         |    |                               |                             |
| · Hispanic/Latino                       | 22 | (21.6%)                       | 3 (15.8%)                   |
| · Not Hispanic/Latino                   | 80 | (78.4%)                       | 16 (84.2%)                  |
| Mother’s Education; n, %                |    |                               |                             |
| · Some College or Less                  | 60 | (60.6%)                       | 10 (55.6%)                  |
| · College Graduate or higher            | 39 | (39.4%)                       | 8 (44.4%)                   |
| Father’s Education; n, %                |    |                               |                             |
| · Some College or Less                  | 54 | (71.1%)                       | 7 (46.7%)                   |
| · College Graduate or Higher            | 22 | (28.9%)                       | 8 (53.3%)                   |
| BMI, kg/m2; median (min, max)           | 105| 31.72 (18.05, 63.61)          | 26.02 (18.05, 29.26)        |
| BMI z-score; median (min, max)          | 105| 2.18 (1.14, 3.78)             | 1.39 (1.14, 1.62)           |
| % Total Body Fat                        | 105| 37.6 (12.2, 61.0)             | 31.75 (12.2, 42.90)         |
| Weight Categories; n, %                 | 105|                               |                             |
| · Overweight                            | 20 | (19.1%)                       |                             |
| Weight categories | Age < 18 years | Age ≥ 18 years |
|-------------------|----------------|----------------|
| Overweight        | BMI 85-95th percentile | BMI 25-30 kg/m² |
| Class 1 obesity   | BMI 95-120% of 95th percentile | BMI 30-35 kg/m² |
| Class 2 obesity   | BMI 120-140% of 95th percentile | BMI 35-40 kg/m² |
| Class 3 obesity   | BMI > 140% of 95th percentile | BMI > 40 kg/m² |

| Laboratory parameters | Definition of Abnormal |
|-----------------------|------------------------|

*number of participants after excluding missing or don’t know/unknown responses for each variable.

**P-values calculated from Fisher Exact Tests for categorical data or Jonckheere-Terpstra Test for Independent Samples for continuous data
| Risk Factor                          | Value                                      | Age Range          |
|-------------------------------------|--------------------------------------------|--------------------|
| Fasting blood glucose               | ≥ 126 mg/dl                                | All ages           |
| Fasting insulin                     | > 12 uIU/mL                                 | All ages           |
| HOMA-IR                             | ≥ 3 units                                  | All ages           |
| C-reactive protein                  | ≥ 3 mg/dl                                  | All ages           |
| LDL                                 | ≥ 110 mg/dl                                | ≥ 120 mg/dl        |
| Total Cholesterol                   | ≥ 170 mg/dl                                | ≥ 190 mg/dl        |
| HDL                                 | ≤ 40 mg/dl                                 | All ages           |
| Triglycerides                       | ≥ 75 mg/dL                                 | ages 2-9 years     |
|                                     | ≥ 90 mg/dL                                 | ages 10-19 years   |
|                                     | ≥ 115                                      | ages ≥ 20 years    |
| SBP                                 | ≥ 95th %tile for age, sex and height       | ages 2-17 years    |

| DBP                                 | ≥ 95th %tile for age, sex and height       | ages 2-17 years    |
|                                     | ≥ 90 mmHg                                  | ages ≥ 18 years    |
| Multiple risk factor variable       | Abnormal values for glucose, LDL, HDL, CRP or BP or taking medications for diabetes, dyslipidemia or hypertension |                    |

Table 3: Metabolic Risk Factors Overall and According to Weight Category
| Characteristic         | n* | % Exceed Cutoff | All      | Overweight       |
|------------------------|----|-----------------|----------|------------------|
| Triglycerides, mg/dL   | 104| 36.5%           | 79.5 (36.0, 362.0) | 62.0 (36.0,362.0) |
| Total Chol, mg/dL      | 104| 43.3%           | 164.0 (118.0,237.0) | 160.5 (122.0,237.0) |
| HDL-Chol, mg/dL        | 104| 53.8%           | 45.0 (24.0, 76.0) | 54.5 (26.0,76.0) |
| LDL- Chol, mg/dL       | 104| 41.3%           | 96.0 (21.0-155.0) | 88.0 (47.0,154.0) |
| SBP, mmHg              | 105| 1.9%            | 110.0 (87.0, 140.0) | 105.0 (90.0,125.0) |
| DBP, mmHg              | 105| 1.0%            | 67.0 (43.5, 85.0) | 63.0 (57.0,81.0) |
| CRP, mg/L              | 104| 28.8%           | 1.63 (0.10, 70.41) | 0.97 (0.10, 3.85) |
| HOMA                   | 103| 53.4%           | 3.08 (0.21, 23.61) | 2.13 (0.21,5.65) |
| Insulin, uIU/mL        | 103| 63.1%           | 16.0 (1.4, 102.8) | 10.6 (1.4, 26.3) |
| Glucose, mg/dL         | 104| 2.9%            | 80.0 (62.0, 255.0) | 80.5 (62.0,120.0) |
| # of risk factors      | 103| 2 (0, 5)        | 1 (0,3) |

*Median (Minimum, Maximum) values for each risk factor

**Number of participants with non-missing data

***P-values calculated from Jonckheere-Terpstra Test for Independent Samples

Table 4: Food Intake and Eating and Activity Behaviors According to Weight Category

| Variable                              | n*  | Weight Category       |
|---------------------------------------|-----|-----------------------|
|                                       |     | Overweight | Obese |
| **Food intake and eating behaviors among all participants** |     |Cos| |
| # servings per day **Water**          | 102 | 5 (26.3%) | |
| · 1-3 /month to 1/day                 |     | 3 (15.8%) | |
| · 2-3 /day                            |     | 11 (57.9%) | |
| · More than 3/day                     |     | | |
| # servings per day **Regular Soda**   | 100 | 6 (31.6%) | |
| · None                                |     | 6 (31.6%) | |
| · 1-3 /month to 1/week                |     | | |
| # servings per day | Diet Soda | Fruits | Vegetables |
|-------------------|-----------|--------|------------|
| None              | 13 (72.2%)| 3 (16.7%)| 1 (5.6%)   |
| 1-3 /month to 1/week | 4 (22.2%)| 3 (16.7%)| 1 (5.6%)   |
| 2-4 /week to more than 3/day | 1 (5.6%)| 12 (66.7%)| 16 (88.9%)|

| # days per week | eat dinner at home; median (min, max) | 102 | 4.0 (0,7.0) |
|-----------------|----------------------------------------|-----|------------|
| eat fast food; median (min, max) | 103 | 1.0 (0,4.0) |
| week eat breakfast; median (min, max) | 95 | 6.0 (0,7.0) |

**Eating behaviors among the subsample of adolescents 13 years and older**

Eat when bored or upset; n, %

|       | 69 |
|-------|----|
| Never to less than once a month | 13 (100%) |
| 1 to 2 times a month | 0 (0%) |
| Once a week or more | 0 (0%) |

Could not stop eating; n, %

|       | 69 |
|-------|----|
| Never to less than once a month | 13 (100%) |
| 1-2 times a month | 0 (0%) |
| Once a week or more | 0 (0%) |

**TFEQ-R18 Eating Behavior Scores**

(0-100); median (min, max)

|       |    |
|-------|----|
| Cognitive Restraint (CR) | 71 |
| Uncontrolled Eating (UE) | 71 |
| Emotional Eating (EE) | 70 |

**Activity behaviors among all participants**

# hours **watching TV** per day during weekdays; median (min, max) | 103 | 3.0 (1.0, 6.0) |
# hours **playing video games** per day during weekdays; median (min, max) | 101 | 3.0 (1.0, 7.0) |
# days per week active **for 30 + mins/day**; median (min, max) | 103 | 3.0 (1.0, 7.0) |
# organized sports teams/physical activities per week; n, % | 103 |
- None per week | 3 (15.8%) |
- One per week | 7 (36.8%) |
- Two or more per week | 9 (47.4%) |

*number of participants after excluding missing or don’t know/unknown responses for each variable

**P-values calculated from Fisher Exact Tests for categorical data or Jonckheere-Terpstra Test for Independent Samples for continuous data

Table 5: Health Related Attitudes and Perceptions

| Variable | n* | Overweight | Obes
| --- | --- | --- | --- |
| General Health | | | |
| Health in General; n, % | 100 | | |
| Fair/Poor | 2 (11.1%) | | |
| Good/Very good/Excellent | 16 (88.9%) | | |
| Health Habits; n, % | 94 | | |
| Fair/Poor | 6 (35.3%) | | |
| Good/Very good/Excellent | 11 (64.7%) | | |
| Perceived Stress (1-10) | 94 | | |
| Fair/Poor | 5.0 (1.0, 9.0) | 6 | |
| Good/Very good/Excellent | | | |
| Quality of Life Scores (0-100); median (min, max) | | | |
| Overall | 100 | 81.5 (48.9, 95.7) | 75.0 |
| Physical Health | 102 | 87.5 (21.9, 100.0) | 78.1 |
| Psychosocial Health | 100 | 80.8 (53.3, 95.0) | 70.0 |
| School Functioning | 101 | 80.0 (45.0, 95.0) | 65.0 |
| Emotional Functioning | 101 | 77.5 (45.0, 100.0) | 70.0 |
| Social Functioning | 100 | 85.0 (45.0, 100.0) | 90.0 |

*number of participants after excluding missing or don’t know/unknown responses
for each variable
**P-values calculated from Fisher Exact Tests for categorical data or Jonckheere-Terpstra Test for Independent Samples for continuous data
