1. General Information

All chemicals were purchased as reagent grade and used without further purification. Solvents for purification (extraction and chromatography) were purchased as technical grade and distilled on the rotary evaporator prior to use. For column chromatography SiO$_2$-(40-63 µm for flash chromatography, VWR Chemicals) was used as stationary phase. Analytical thin layer chromatography (TLC) was performed on aluminum foil pre-coated with SiO$_2$-60 F$_{254}$ (Merck) and visualised with a UV-lamp (254 nm) or CAM stain solution. Concentration in vacuo was performed at ~10 mbar and 40 °C, drying at ~10$^{-2}$ mbar and rt. NMR spectra were measured by the NMR service of the Organisch-Chemisches Institut, Westfälische Wilhelms-Universität Münster on a Bruker AV300, Bruker AV400, Agilent DD2 500 or Agilent DD2 600 spectrometer at room temperature. The resonance multiplicity is abbreviated as: s (singlet), d (doublet), t (triplet), q (quadruplet), m (multiplet) and b (broad). Assignments of unknown compounds are based on DEPT, COSY (HH and FF), HMBC, HSQC and NOESY spectra. Melting points were measured on a Büchi B-545 melting-point apparatus in open capillaries and are uncorrected. IR spectra were recorded on a Perkin-Elmer 100 FT-IR spectrometer, selected adsorption bands are reported in wavenumbers (cm$^{-1}$) and intensities are reported as: w (weak), m (medium), s (strong) and br (broad). Mass spectra were measured by the MS service of the Organisch-Chemisches Institut, Westfälische Wilhelms-Universität Münster. Isomerisation reactions were performed utilising a UVA LED (emission spectrum see Figure 1). Further isomerisation reactions were performed with a Winger WEPRB3-S1 Power LED Star royalblue (450 nm) 3 W (emission spectrum see Figure 2) and a set up of 4 Winger WEPUV3-S2 UV Power LED Star (Schwarzlicht) 1.2 W lamps (emission spectrum see Figure 3). The forward current per chip was set to 700 mA, the resulting forward voltage was 3.4 V while the resulting radiant flux was 3000 mW and 1200 mW for the 450 nm- and the 402 nm-lamp, respectively. The distance between the reaction vessels and the UV-lamp was set at approximately 0.5 cm.

2.2. Photosensitised isomerisation of vinyl silanes

General Procedure E for the isomerisation of vinyl silanes

A round-bottom flask was charged with the specific vinyl silane (0.1 mmol, 1.0 eq.) and benzophenone (0.005 mmol, 0.05 eq.) in degassed cyclohexane (1.5 mL). The reaction vessel was sealed with a septum, equipped with an argon balloon and placed above the UV-lamp with a distance of approximately 0.5 cm. The mixture was stirred for 2 h at room temperature under UV light irradiation (UVA LED, 365 nm). The crude reaction mixture was filtered through a plug of SiO$_2$, diluted with cyclohexane (5 mL) and concentrated in vacuo. The E/Z-isomer ratio was determined by the integration of the $^1$H NMR spectra.

A flame-dried Schlenk-tube was charged with Z-21 (20.6 mg, 0.1 mmol, 1.0 eq.) and dry THF (0.5 mL). TBAF (1.0 M in THF, 0.2 mL, 0.2 mmol, 2.0 eq.) was added slowly at room temperature and the mixture was stirred for 15 min. 4-Iodoanisole (23.4 mg, 0.1 mmol, 1.0 eq.) and Pd(dba)$_2$ (2.8 mg, 0.005 mmol, 0.05 eq.) were sequentially added before the reaction was stirred at room temperature overnight. After filtration through a pad of silica and dilution with EtOAc, the crude reaction mixture was concentrated in vacuo. Purification by column chromatography (CH) yielded a colorless oil (19.1 mg, 80%); analytical data in agreement with the literature.$^{[18]}$

4. DFT CALCULATIONS

Method

All structures were optimised without geometry constraints using the TPSS functional[21] and an atom-pairwise dispersion correction (D3)[22]. A flexible triple zeta basis set (def2-TZVP)[23] was used in all calculations. For the calculation of the free enthalpy contributions (G\text{RRHO}(298K)), a rotor approximation was applied for vibrational modes with wave numbers below 100 cm\textsuperscript{-1}.\[24] The nature of all optimised stationary points was proven by the presence of either 0 (minimum) or 1 (transition structure) imaginary vibrational frequency.

Electronic energies were recalculated with the double hybrid functional PWPB95(-D3)[25] using the structures optimised with TPSS-D3. In PWPB95, a component of the correlation energy is computed by perturbation theory, it performs more accurately in the determination of energies, even for open shell molecules such as radicals or triplet states. The final value for the free enthalpy ΔG(298) was obtained using the PWPB95-D3 electronic energies and G\text{RRHO}(298K), obtained with TPSS-D3.

Using the TPSS-D3 S\textsubscript{0} geometries, singlet and triplet excitation energies were calculated with TD-DFT using the B-LYP functional[26]. Energies and spin densities of the T\textsubscript{1} states were calculated with PWPB95-D3/def2-TZVP.

All geometry optimisations and vibrational frequency calculations were performed with the TURBOMOLE 7.3 program,[27] TDDFT and PWPB95-D3 single point calculations were performed with the ORCA (4.0.2) program.[28]

Orbital analysis of the triplet excitation of (E)- and (Z)-1

In both ground (S₀) states of (E)-1 and (Z)-1, HOMO and LUMO (MOs 55 and 56) are constituted mainly by the π/π* orbitals of the ethene bond, with significant admixture of phenyl π orbitals.

The (forbidden) first triplet excitation to T₁ of (E)-1 corresponds to a HOMO-LUMO excitation. The two singly occupied orbitals of T₁ (MOs 55a and 56a) are both delocalised over the styryl system and lead in total to a localisation of spin density in the vinyl group, allowing the triplet state to attain the energy minimum by rotation around the vinyl C-C bond.

The more distorted styryl moiety of (Z)-1, however, shows a significantly higher energy of the forbidden first vertical triplet excitation (87 kcal/mol) in the TDDFT (B-LYP) calculation and of the energy of the (relaxed) T₁ wave function (100 kcal/mol with PWPB95-D3) at the same geometry. The larger torsional angle (61.6°) aggravates the mixing of ethene and phenyl π orbitals and leads to two rather localised α spin orbitals in the T₁ state (MOs 55a and 56a in Figure S6). Spin density is accumulated mainly in the phenyl ring, suggesting a lower tendency to rotate the vinyl C-C bond. Of course, thermal motion would allow the molecule to leave the S₀ minimum geometry and change the spin density distribution in the further course.
