ON THE REPRESENTATIONS OF INTEGERS BY THE SEXTENARY QUADRATIC FORM $x^2 + y^2 + z^2 + 7s^2 + 7t^2 + 7u^2$ AND 7-CORES

ALEXANDER BERKOVICH AND HAMZA YESILYURT

Abstract. In this paper we derive an explicit formula for the number of representations of an integer by the sextenary form $x^2 + y^2 + z^2 + 7s^2 + 7t^2 + 7u^2$. We establish the following intriguing inequalities

$$2b(n) \geq a_7(n) \geq b(n) \quad \text{for} \quad n \neq 0, 2, 6, 16.$$

Here $a_7(n)$ is the number of partitions of $n$ that are 7-cores and $b(n)$ is the number of representations of $n + 2$ by the sextenary form $(x^2 + y^2 + z^2 + 7s^2 + 7t^2 + 7u^2)/8$ with $x, y, z, s, t$ and $u$ being odd.

1. Introduction

Recall that a partition is called a $t$-core if it has no rim hooks of length $t$ [10]. Let $a_t(n)$ be the number of $t$-core partitions of $n$. It is well known that [11], [8]

$$\sum_{n \geq 0} a_t(n)q^n = \sum_{\pi \in \mathcal{P}_t, \pi \vdash n} q^{|\pi|} \frac{E^t(q)}{E(q)},$$

where

$$\vec{b}_t := \langle 0, 1, 2, ..., t-1 \rangle, \quad \vec{1}_t := \langle 1, 1, ..., 1 \rangle,$$

$$E(q) := \prod_{n=1}^{\infty} (1 - q^n).$$

Let

$$\varphi(q) := \sum_{n=-\infty}^{\infty} q^{n^2}, \quad \psi(q) := \sum_{n=0}^{\infty} q^{n(n+1)/2}.$$

Throughout the paper we assume that $q$ is a complex number with $|q| < 1$. For convenience, the coefficient of $q^n$ in the expansion of $H(q)$ will be denoted as $[q^n]H(q)$. For a partition $\pi$, BG-rank($\pi$) is defined as an alternating sum of parities of parts of $\pi$ [2], [3]. In [4], the authors found positive eta-quotient representations for the 7-core generating functions $\sum_{n \geq 0} a_{7,j} (n)q^n$, where $a_{7,j}(n)$ denotes the number of 7-cores of $n$ with BG-rank = $j$ and established a number of inequalities for $a_{7,j}(n)$ with $j = -1, 0, 1, 2$ and $a_7(n)$. In this paper, we prove lower and upper bounds for $a_7(n)$, namely,

Theorem 1.1.

$$[q^n] \left(1 + 5q^6 + q^{16} + 2q^3(q)^3(q)\psi^3(q)\psi^7(q)\right) \geq [q^n] \frac{E^7(q)}{E(q)},$$

where the inequality is strict if $n \neq 0, 6$ or 16.

Theorem 1.2.

\[ [q^n] \left( \frac{E^7(q^7)}{E(q)} + q^2 \right) \geq [q^n] \left( q^3(q)\psi^3(q^7) \right). \]  

We should remark that the inequality in (1.5) is only strict as it can be seen in the proof of Theorem 1.2 when \( n \) is even and \( n \neq 2 \). Theorem 1.1 and Theorem 1.2 are proved in sections 5 and 6.

It is well known that every integer can be written as sum of three triangular numbers, that is \( [q^n]\psi^3(q) > 0 \) for all \( n \geq 0 \). This together with (1.5) implies that

\[ [q^n] \frac{E^7(q^7)}{E(q)} > 0 \text{ for all } n \geq 3, \text{ and hence for all } n \geq 0. \]

In fact, Granville and Ono showed that [9] if \( t \geq 4 \), then

\[ [q^n] \frac{E^t(q^7)}{E(q)} > 0 \text{ for all } n \geq 0. \]

The lower bound given by (1.5) improves the Granville-Ono result when \( t = 7 \).

Essential to our proofs are the following theta function identities which we prove in section 4 by employing the theory of modular equations

Theorem 1.3.

\[ 7\varphi^3(-q)\varphi^3(-q^7) = -49 \left( q^2 \frac{E^7(q^7)}{E(q)} + qE^3(q)E^3(q^7) \right) \]

\[ + 56 \left( 7q^4 \frac{E^7(q^{14})}{E(q^2)} + q^2E^3(q^2)E^3(q^{14}) \right) - \frac{E^7(q)}{E(q^7)} - 8 \frac{E^7(q^2)}{E(q^{14})}, \]

and

\[ 56q^3\psi^3(q)\psi^3(q^7) = 49q^2 \frac{E^7(q^7)}{E(q)} + 7qE^3(q)E^3(q^7) \]

\[ - 49 \left( q^4 \frac{E^7(q^{14})}{E(q^2)} + q^2E^3(q^2)E^3(q^{14}) \right) + \frac{E^7(q)}{E(q^7)} - \frac{E^7(q^2)}{E(q^{14})}. \]

The rest of the paper is organized as follows. In the next section, we recall two Lambert series identities of Ramanujan which we extensively use in our proofs. In section 3, we give a brief introduction to modular equations. Then, we prove Theorem 1.3 and from it we derive an explicit formulas for the number of representations of an integer by the sextenary forms \( x^2 + y^2 + z^2 + 7s^2 + 7t^2 + 7u^2 \) and \( (x^2 + y^2 + z^2 + 7s^2 + 7t^2 + 7u^2)/8 \) with \( x, y, z, s, t \) and \( u \) being odd for the later case. In the last two sections, Theorem 1.1 and Theorem 1.2 are proven.

2. Two Lambert Series Identities of Ramanujan

We start with two Lambert series identities of Ramanujan[6] which we will employ in our proofs.

\[ L(q) := \frac{8}{7} \left( 1 - \frac{E^7(q)}{E(q^7)} \right) - 7qE^3(q)E^3(q^7) \]

\[ = \sum_{n=1}^{\infty} \left( \frac{n}{7} \right) \frac{n^2 q^n}{1 - q^n} \]

and

\[ K(q) := 8q^2 \frac{E^7(q^7)}{E(q)} + qE^3(q)E^3(q^7) \]

\[ = \sum_{n=1}^{\infty} \left( \frac{n}{7} \right) \frac{q^n(1 + q^n)}{(1 - q^n)^3}. \]
We should remark that (2.1) and (2.2) are equivalent under the imaginary transformation [7]. It is easy to see that

\[(2.3)\quad L(q) = \sum_{n=1}^{\infty} \left( \sum_{d | n} d^2 \left( \frac{d}{7} \right) \right) q^n \quad \text{and} \quad K(q) = \sum_{n=1}^{\infty} \left( \sum_{d | n} d^2 \left( \frac{n/d}{7} \right) \right) q^n.\]

The coefficients of \(L(q)\) and \(K(q)\) are clearly multiplicative. The reader may wish to consult [1] for background on multiplicative functions, convolution of multiplicative functions and Legendre’s symbol. Using multiplicity it is easy to conclude from (2.3) that

\[(2.4)\quad \left[ q^n \right] L[q] = (-1)^b \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{1 - p_i^{2}} \prod_{j=1}^{s} \frac{(-1)^{w_j} + q_j^{2w_j+2}}{1 + q_j^{2}},\]

\[(2.5)\quad \left[ q^n \right] K[q] = 7^c \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{1 - p_i^{2}} \prod_{j=1}^{s} \frac{(-1)^{w_j} + q_j^{2w_j+2}}{1 + q_j^{2}},\]

where \(n\) has the prime factorization

\[n = 7^c \prod_{i=1}^{r} p_i^{v_i} \prod_{j=1}^{s} q_j^{w_j},\]

with \(p_i \equiv 1, 2, 4 \pmod{7}\), \(q_j \equiv 3, 5, 6 \pmod{7}\), and \(b = \sum_{j=1}^{s} w_j\). We note that (2.5) was stated as Lemma 1 in [8].

Next, let

\[(2.6)\quad M(q) := qE^3(q)E^3(q^{7}).\]

From [8, p. 11, Lemma 2], we have

\[(2.7)\quad \left[ q^n \right] M(q) = \begin{cases} (-7)^c \prod_{i=1}^{r} F(p_i, v_i) \prod_{j=1}^{s} q_j^{w_j} & \text{if each } w_j \text{ is even} \\ 0 & \text{otherwise} \end{cases},\]

where the prime factorization of \(n\) is defined as above and

\[(2.8)\quad F(p, r) := \frac{\beta^{2r+2} - \bar{\beta}^{2r+2}}{\beta^2 - \bar{\beta}^2}\]

with

\[\beta = x + \sqrt{-7}y, \quad \bar{\beta} = x - \sqrt{-7}y,\]

where \(x\) and \(y\) are the positive unique integers satisfying \(p = x^2 + 7y^2\) provided \(p \equiv 1, 2, 4 \pmod{7}\) and \(p > 2\). If \(p = 2\), then

\[\beta = (1 + \sqrt{-7})/2, \quad \bar{\beta} = (1 - \sqrt{-7})/2.\]

Next, We give background information on modular equations.

### 3. Modular Equations

For \(0 < k < 1\), the complete elliptic integral of the first kind \(K(k)\), associated with the modulus \(k\), is defined by

\[K(k) := \int_{0}^{\pi/2} \frac{d\theta}{\sqrt{1 - k^2 \sin^2 \theta}}.\]

The number \(k^* := \sqrt{1 - k^2}\) is called the complementary modulus. Let \(K, K', L, \) and \(L'\) denote complete elliptic integrals of the first kind associated with the moduli \(k, k', \ell,\) and \(\ell'\), respectively. Suppose that

\[(3.1) \quad \frac{K'}{K} = \frac{L'}{L}.\]
for some positive rational integer \( n \). A relation between \( k \) and \( \ell \) induced by (3.1) is called a modular equation of degree \( n \). There are several definitions of a modular equation in the literature. For example, see the books by R. A. Rankin [12, p. 76] and B. Schoeneberg [13, pp. 141–142]. Following Ramanujan, set

\[
\alpha = k^2 \quad \text{and} \quad \beta = \ell^2.
\]

We often say that \( \beta \) has degree \( n \) over \( \alpha \). If

\[
q = \exp(-\pi K'/K),
\]

two of the most fundamental relations in the theory of elliptic functions are given by the formulas [5, pp. 101–102],

\[
\varphi^2(q) = \frac{2}{\pi} K(k) \quad \text{and} \quad \alpha = k^2 = 1 - \frac{\varphi^4(-q)}{\varphi^4(q)}.
\]

The equation (3.3) and elementary theta function identities make it possible to write each modular equation as a theta function identity. Ramanujan derived an extensive “catalogue” of formulas [5, pp. 122–124] giving the “evaluations” of \( E(q), \varphi(q), \psi(q), \) and \( \chi(q) \) at various powers of the arguments in terms of

\[
z := z_1 := \frac{2}{\pi} K(k), \quad \alpha, \quad \text{and} \quad q.
\]

The evaluations that will be needed in this paper are as follows

\[
\phi(-q) = \sqrt{z}((1 - \alpha))^{1/4},
\]

\[
\psi(-q) = q^{-1/8} \sqrt{\frac{1}{2}} z \{\alpha(1 - \alpha)\}^{1/8},
\]

\[
E(-q) = 2^{-1/6} q^{-1/24} \sqrt{z} \{\alpha(1 - \alpha)\}^{1/24},
\]

\[
E(q^2) = 2^{-1/3} q^{-1/12} \sqrt{z} \{\alpha(1 - \alpha)\}^{1/12},
\]

\[
E(q^4) = 4^{-1/3} q^{-1/6} \sqrt{z} \alpha^{1/6} (1 - \alpha)^{1/24}.
\]

We should remark that in the notation of [5], \( E(q) = f(-q) \). If \( q \) is replaced by \( q^n \), then the evaluations are given in terms of

\[
z_n := \frac{2}{\pi} K(l), \quad \beta, \quad \text{and} \quad q^n,
\]

where \( \beta \) has degree \( n \) over \( \alpha \).

Lastly, the multiplier \( m \) of degree \( n \) is defined by

\[
m = \frac{\varphi^2(q)}{\varphi^2(q^n)} = \frac{z}{z_n}.
\]

The proofs of the following modular equations of degree 7 can be found in [5, p. 314, Entry 19(i),(iii), (viii)]

\[
(\alpha \beta)^{1/8} + \{\{1 - \alpha\}(1 - \beta)\}^{1/8} = 1,
\]

\[
m = \frac{1 - 4 \left(\frac{\beta^7 (1 - \beta)^7}{\alpha(1 - \alpha)}\right)^{1/24}}{\left\{\{1 - \alpha\}(1 - \beta)\}^{1/8} - (\alpha \beta)^{1/8}\right\}^{7/4}, \quad \frac{7}{m} = \frac{1 - 4 \left(\frac{\alpha^7 (1 - \alpha)^7}{\beta(1 - \beta)}\right)^{1/24}}{\left\{\{1 - \alpha\}(1 - \beta)\}^{1/8} - (\alpha \beta)^{1/8}\right\}^{1/4},
\]

\[
m - 7/m = 2\left((\alpha \beta)^{1/8} - \{\{1 - \alpha\}(1 - \beta)\}^{1/8}\right) \left(2 + (\alpha \beta)^{1/4} + \{\{1 - \alpha\}(1 - \beta)\}^{1/4}\right).
\]
4. Proof of Theorem 1.3

In the language of modular equations the identities (1.6) and (1.7) are reciprocals of each other [5, p. 216, Entry 24(v)] and so we only prove (1.7). In (1.7), we replace $q$ by $-q$ and use the evaluations given in (3.5)–(3.7), we find that

$$-7\sqrt{z^2}\sqrt{z^2}\left\{\alpha\beta(1-\alpha)(1-\beta)\right\}^{3/8}
-\frac{49}{2}\sqrt{z^2}\left(\frac{\beta^7(1-\beta)^7}{\alpha(1-\alpha)}\right)^{1/24}
+\frac{7}{2}\sqrt{z^2}\sqrt{z^2}\left\{\alpha\beta(1-\alpha)(1-\beta)\right\}^{1/8}
-\frac{49}{4}\sqrt{z^2}\left(\frac{\beta^7(1-\beta)^7}{\alpha(1-\alpha)}\right)^{1/12}
-\frac{49}{4}\sqrt{z^2}\sqrt{z^2}\left\{\alpha\beta(1-\alpha)(1-\beta)\right\}^{1/4}
+\frac{1}{2}\sqrt{z^2}\left(\frac{\alpha^7(1-\alpha)^7}{\beta(1-\beta)}\right)^{1/24}
-\frac{1}{4}\sqrt{z^2}\sqrt{z^2}\left(\frac{\alpha^7(1-\alpha)^7}{\beta(1-\beta)}\right)^{1/12}
\tag{4.1}
$$

We divide both sides of (4.1) by $\sqrt{z^2}\sqrt{z^2}$ and use (3.9) and conclude that (4.1) is equivalent to

$$\frac{49}{m^2}\left\{1-\left(\frac{\beta^7(1-\beta)^7}{\alpha(1-\alpha)}\right)^{1/24}\right\}^2
+\frac{7}{4}\left\{1-\left(\frac{\alpha^7(1-\alpha)^7}{\beta(1-\beta)}\right)^{1/24}\right\}^2
+7\left\{4\alpha\beta(1-\alpha)(1-\beta)\right\}^{3/8}
-2\left\{\alpha\beta(1-\alpha)(1-\beta)\right\}^{1/8}
-7\left\{\alpha\beta(1-\alpha)(1-\beta)\right\}^{1/4} = 0.
\tag{4.2}
$$

We prove (4.2).

Set $t := (\alpha\beta)^{1/8}$. Then, by (3.10), we have

$$\left\{(1-\alpha)(1-\beta)\right\}^{1/8} = 1-t.
\tag{4.3}
$$

Let $x := 1-2t$, from (3.11), we have

$$\left(\frac{\beta^7(1-\beta)^7}{\alpha(1-\alpha)}\right)^{1/24} = \frac{1-xm}{4}
\text{ and } \left(\frac{\alpha^7(1-\alpha)^7}{\beta(1-\beta)}\right)^{1/24} = \frac{1+7x/m}{4}.
\tag{4.4}
$$

Similarly, (3.12) is equivalent to

$$m-7/m = 2(2t-1)(2t^2-2t+3).
\tag{4.5}
$$

Now using (4.4) and (4.5), we find after some algebra that

$$\frac{49}{m^2}\left\{1-\left(\frac{\beta^7(1-\beta)^7}{\alpha(1-\alpha)}\right)^{1/24}\right\}^2
+\frac{7}{16}\left( (m-7/m)^2 + 6x(m-7/m) - 14x^2 + 14 \right)
\tag{4.6}
$$

Moreover,

$$7\left\{4\alpha\beta(1-\alpha)(1-\beta)\right\}^{3/8}
-2\left\{\alpha\beta(1-\alpha)(1-\beta)\right\}^{1/8}
-7\left\{\alpha\beta(1-\alpha)(1-\beta)\right\}^{1/4}
= 7(4t^3(1-t)^3 - 2t(1-t) - 7t^2(1-t)^2)
\tag{4.7}
$$

This completes the proof of (4.2). Hence the proof of Theorem 1.3 is complete. Next, we determine $|q^n(x^2+y^2+z^2+7s^2+7t^2+7u^2)$ and $|q^n(y^2+z^2+7s^2+7t^2+7u^2)/8$ with $x, y, z, t$ and $u$ being odd for the later case.
Corollary 4.1. Suppose $n$ has the prime factorization
\[ n = 7^c \cdot 2^d \prod_{i=1}^{r} p_i^{v_i} \prod_{j=1}^{s} q_j^{u_j}, \]
with $p_i$ odd $p_i \equiv 1, 2, 4 \pmod{7}$, $q_j \equiv 3, 5, 6 \pmod{7}$, and $b = \sum_{j=1}^{s} w_j$.

if $n$ is odd, then
\[
[q^n] (\phi^3(q)\phi^3(q^7)) = \frac{1}{8} (7^{2c+1} - (-1)^b) \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{1 - p_i^2} \prod_{j=1}^{s} \frac{(-1)^{w_j} + q_j^{2u_j+2}}{1 + q_j^2}
\]

(4.8)
\[+ \frac{21}{4} (-7)^c \prod_{i=1}^{r} F(p_i, v_i) \prod_{j=1}^{s} q_j^{u_j} (1 + (-1)^{w_j}) \frac{1}{2}, \]

if $n$ is even, then
\[
[q^n] (\phi^3(q)\phi^3(q^7)) = \frac{1}{24} (7^{2c+1} - (-1)^b)(4^d+1) \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{1 - p_i^2} \prod_{j=1}^{s} \frac{(-1)^{w_j} + q_j^{2u_j+2}}{1 + q_j^2}
\]

\[ - \frac{3}{4} (-7)^c (7F(2, d) + 8F(2, d - 1)) \prod_{i=1}^{r} F(p_i, v_i) \prod_{j=1}^{s} q_j^{u_j} (1 + (-1)^{w_j}) \frac{1}{2}. \]

(4.9)

Proof. From (1.6) with $q$ replaced by $-q$, and the definitions (2.1), (2.2), and (2.6), we have that
\[
8\phi^3(q)\phi^3(q^7) = 8 + L(-q) - 7K(-q) - 8L(q^2) + 56K(q^2) - 42M(-q) - 48M(q^2).
\]
Therefore,
\[
8[q^{2n+1}] (\phi^3(q)\phi^3(q^7)) = [q^{2n+1}] (7K(q) - L(q) + 42M(q))
\]
and
\[
8[q^{2n}] (\phi^3(q)\phi^3(q^7)) = [q^{2n}] (8 + L(q) - 8L(q^2) - 7K(q) + 56K(q^2) - 42M(q) - 48M(q^2)).
\]
These two equations together with (2.4), (2.5) and (2.7) imply (4.8) and (4.9). 

\[\square\]

Corollary 4.2. Suppose $n$ has the prime factorization
\[ n = 7^c \cdot 2^d \prod_{i=1}^{r} p_i^{v_i} \prod_{j=1}^{s} q_j^{u_j}, \]
with $p_i$ odd $p_i \equiv 1, 2, 4 \pmod{7}$, $q_j \equiv 3, 5, 6 \pmod{7}$, and $b = \sum_{j=1}^{s} w_j$.

if $n$ is odd, then
\[
[q^n] (\psi^3(q)\psi^3(q^7)) = \frac{1}{64} (7^{2c+1} - (-1)^b) \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{1 - p_i^2} \prod_{j=1}^{s} \frac{(-1)^{w_j} + q_j^{2u_j+2}}{1 + q_j^2}
\]

\[ - \frac{3}{32} (-7)^c \prod_{i=1}^{r} F(p_i, v_i) \prod_{j=1}^{s} q_j^{u_j} (1 + (-1)^{w_j}) \frac{1}{2}, \]

(4.13)
if $n$ is even, then
\[
[q^n] (\psi^3(q)\psi^3(q^7)) = \frac{1}{64} 4^d (7^{2c+1} - (-1)^b) \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{1 - p_i^2} \prod_{j=1}^{s} \frac{(-1)^{w_j} + q_j^{2u_j+2}}{1 + q_j^2}
\]

\[ - \frac{3}{32} (-7)^c (F(2, d) + 7F(2, d - 1)) \prod_{i=1}^{r} F(p_i, v_i) \prod_{j=1}^{s} q_j^{u_j} (1 + (-1)^{w_j}) \frac{1}{2}. \]

(4.14)
The proof of Corollary 4.2 is very similar to that of Corollary 4.1 and we forgo its proof.

5. Proof of Theorem 1.1

From (1.7) and the definitions (2.1), (2.2), and (2.6), we have that
\[
32q^2 \left( 2q\psi^3(q)\psi^3(q^7) - \frac{E^7(q^7)}{E(q)} \right)
= 3K(q) - 7K(q^2) - L(q) - 2M(q) + L(q^2) - 42M(q^2).
\]
Explicit check shows that (1.4) is valid for \( n = 0, 6 \) or \( n = 16 \) and so we assume in this section that \( n \neq 0, 6, 16 \). From (5.1), we see that
\[
(5.2) \quad 32q^{2n-1} \left( 2q\psi^3(q)\psi^3(q^7) - \frac{E^7(q^7)}{E(q)} \right) = [q^{2n+1}] (3K(q) - L(q) - 2M(q)).
\]
Let \( r(n) := [q^n] (3K(q) - L(q) - 2M(q)) \). Instead of proving that (5.2) is nonnegative, we will prove the stronger statement that if \( n > 1 \), then
\[
(5.3) \quad r(n) > 0.
\]
If \( [q^n] M(q) = 0 \), then by (2.4) and (2.5), we have that
\[
r(n) = [q^n] (3K(q) - L(q))
= (3.72c - (1)^b) \prod_{i=1}^{r} \frac{1 - p_i^{2v_i + 2}}{1 - p_i^2} \prod_{j=1}^{s} \frac{(-1)^{w_j} + q_j^{2w_j + 2}}{1 + q_j^2} > 0,
\]
where \( n \) has the prime factorization
\[
n = \prod_{i=1}^{r} p_i^{v_i} \prod_{j=1}^{s} q_j^{w_j},
\]
with \( p_i \equiv 1, 2, 4 \mod 7 \), \( q_j \equiv 3, 5, 6 \mod 7 \), and \( b = \sum_{j=1}^{s} w_j \).

Let \( s(n) := [q^n] M(q) \), assuming now that \( s(n) \neq 0 \), we have by (2.4), (2.5), (2.7),
\[
(5.5) \quad r(n) = |s(n)| 7^{-c} \left\{ (3.72c - 1) \prod_{i=1}^{r} \frac{1 - p_i^{2v_i + 2}}{1 - p_i^2} \prod_{j=1}^{s} \frac{1 + q_j^{2w_j + 2}}{q_j^w (1 + q_j^2)} - 2.7^c \frac{s(n)}{|s(n)|} \right\}.
\]
From (2.8), we observe that
\[
F(p, r) = \frac{\beta^{2r+2} - \beta^{2r+2}}{\beta^2 - \beta^2} = \beta^{2r} + \beta^{2r-2} \beta^2 + \ldots + \beta^{2r},
\]
where \( p = \beta \). Therefore,
\[
(5.6) \quad |F(p, r)| \leq (r + 1)p^r.
\]
It is easy to show that if \( p \) and \( q \) as above and \( w \) is even, then
\[
(5.7) \quad \frac{1 - p^{2v + 2}}{|F(p, v)|(1 - p^2)} \geq \begin{cases} 
11 & \text{if } p > 2 \text{ or } v > 2 \\
5/3 & \text{if } p = 2, v = 1 \\
21/5 & \text{if } p = 2, v = 2 \end{cases}
\]
and
\[
(5.8) \quad \frac{q^{2w+2} + 1}{q^w (1 + q^2)} \geq \begin{cases} 
11 & \text{if } q > 3 \text{ or } w > 3 \\
8 & \text{if } q = 3, w = 2. \end{cases}
\]
Using (5.7) and (5.8) in (5.5), we conclude that
\[
(5.9) \quad r(n) \geq 7^{-c} \left( (3.72c - 1). \frac{5}{3} - 2.7^c \right) > 7^{-c} \left( (3.72c - 1) - 2.7^c \right) \geq 0.
\]
Next, we look at even-indexed coefficients. From (5.1), we find that
\begin{equation}
32[q^{2r}] \left(2q\varphi(q)\psi(q) - \frac{E^7(q^7)}{E(q)} \right)
\end{equation}
\begin{equation}
(5.10)
= [q^{2n+2}] \left(3K(q) - 7K(q^2) - L(q) - 2M(q) + L(q^2) - 42M(q^2) \right).
\end{equation}
Therefore, it remains to prove
\begin{equation}
[q^n] \left(3K(q) - 7K(q^2) - L(q) - 2M(q) + L(q^2) - 42M(q^2) \right) > 0,
\end{equation}
where \( n \) is an even integer, \( n \neq 0 + 2 = 2, 6 + 2 = 8 \) or \( 16 + 2 = 18 \). Suppose \( n \) has the prime factorization
\begin{equation}
n = 7^c2^d \prod_{i=1}^{r} p_i^{w_i} \prod_{j=1}^{s} q_j^{w_j},
\end{equation}
where \( p_i \) odd \( p_i \equiv 1, 2, 4 \pmod{7} \), \( q_j \equiv 3, 5, 6 \pmod{7} \), \( b = \sum_{j=1}^{s} w_j \) and \( d > 0 \). Employing (2.4) and (2.5), we find that
\begin{equation}
[q^n] \left(3K(q) - 7K(q^2) - L(q) + L(q^2) \right)
= \frac{1}{3} (7^{2c}(5.4^d + 4) - (-1)^b 3.4^d) \prod_{i=1}^{r} \frac{1 - p_i^{2w_i+2}}{1 - p_i^2} \prod_{j=1}^{s} \frac{(-1)^{w_j} + q_j^{2w_j+2}}{1 + q_j^2} > 0,
\end{equation}
which proves (5.11) if \([q^n]M(q) = 0\). Thus, we assume now that \([q^n]M(q) \neq 0\) that is \( w_i \) and hence \( b \) are all even, by (2.7), we find that
\begin{equation}
[q^n] \left(3K(q) - 7K(q^2) - L(q) - 2M(q) + L(q^2) - 42M(q^2) \right)
= \prod_{j=1}^{s} q_j^{w_j} \prod_{i=1}^{r} \left| F(p_i, v_i) \right| \left\{ \frac{1}{3} (7^{2c}(5.4^d + 4) - 3.4^d) \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{1 - p_i^2} \prod_{j=1}^{s} \frac{1 + q_j^{2w_j+2}}{1 + q_j^2} q_j^{w_j} \right. \left\} \right|
= \frac{1}{3} (7^{2c}(5.4^d + 4) - 3.4^d) \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{(1 - p_i^2)F(p_i, v_i)} \prod_{j=1}^{s} \frac{1 + q_j^{2w_j+2}}{(1 + q_j^2)q_j^{w_j}}
\end{equation}
\begin{equation}
(5.12)
\geq \frac{1}{3} (7^{2c}(5.4^d + 4) - 3.4^d) \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{(1 - p_i^2)F(p_i, v_i)} \prod_{j=1}^{s} \frac{1 + q_j^{2w_j+2}}{(1 + q_j^2)q_j^{w_j}}
\end{equation}
Let
\begin{equation}
S_1 := \frac{1}{3} (7^{2c}(5.4^d + 4) - 3.4^d) A(n) - 2.7^c \left| F(2, d) + 21F(2, d - 1) \right|,
\end{equation}
where
\begin{equation}
A(n) := \prod_{i=1}^{r} \frac{1 - p_i^{2v_i+2}}{(1 - p_i^2)F(p_i, v_i)} \prod_{j=1}^{s} \frac{1 + q_j^{2w_j+2}}{(1 + q_j^2)q_j^{w_j}}.
\end{equation}
From (5.7), (5.8), and (5.6), we find that
\begin{equation}
(5.15)
S_1 \geq S_2 := \frac{1}{3} (7^{2c}(5.4^d + 4) - 3.4^d) - 2.7^c \left| F(2, d) + 21F(2, d - 1) \right|
\end{equation}
\begin{equation}
(5.16)
> S_3 := \frac{1}{3} (7^{2c}(5.4^d + 4) - 3.4^d) - 2.7^c ((d + 1)2^d + 21d2^{d-1})
\end{equation}
\begin{equation}
(5.17)
= \frac{7^c}{3} (7^{5c}(5.4^d + 4) - 3.4^d - 3(23d + 2)2^d).
\end{equation}
It is easy to show that \( S_2 > 0 \) if \( c \geq 1 \) except for \( c = 1 \) and \( d = 2 \) but \( S_2 > 0 \) for \( c = 1 \) and \( d = 2 \). Observe that \( S_2 > 0 \) if \( d > 8 \) and \( c = 0 \). Direct evaluation shows that \( S_2 > 0 \) if \( c = 0, d = 4, 5, 6, 7 \) or 8. For the remaining cases, \( c = 0, d = 1, 2, \) or 3, by (5.7) and (5.8), we have that \( A(n) \geq 11 \) unless
n = 2^d 3^w with 0 ≤ w ≤ 2. The validity of (5.11) can easily be checked for n = 4, 12, 36 (n = 2, 8 or 18 and w = 1 are already excluded). Assuming A(n) ≥ 11, direct computation show that S_1 > 0 if c = 0, d = 1, 2, or 3. Hence, the proof of Theorem 1.1 is complete.

6. Proof of Theorem 1.2

From (1.7), and the definitions (2.1), (2.2), and (2.6), we find that

\[64q^n \left( \frac{E^7(q^7)}{E(q)} - q^3 \psi(q) \psi^3(q^7) \right)\]

(6.1) \[= L(q) - L(q^2) + K(q) - K(q^2) - 2M(q) + 6(K(q^2) + 7M(q^2)) + 2K(q^2).\]

It is clear from (2.5) that \([q^n]K(q^2) > 0\). Below we assume that \(n ≠ 2\). Validity of (1.5) for the corresponding value of n = 2 can easily be checked. Therefore, it suffices to prove that if \(n ≠ 2\), then

(6.2) \([q^n](K(q)+7M(q)) > 0\)

and

(6.3) \([q^n](L(q) - L(q^2) + K(q) - K(q^2) - 2M(q)) ≥ 0.\)

We start with (6.2). From (2.5),

(6.4) \([q^n](L(q) + 7M(q)) ≥ 0 \text{ if } s(n) := [q^n]M(q) = 0.\)

Assuming that \(s(n) ≠ 0\), by (2.5), (2.7), (5.7), and by (5.8), we find that

(6.5) \(\frac{[q^n]K(q)}{|s(n)|} = \prod_{i=1}^r \frac{1 - p_i^{2v_i + 2}}{(1 - p_i^2)|F(p_i, v_i)|} \prod_{j=1}^s \frac{1 + q_j^{w_j + 2}}{q_j^{w_j}(1 + q_j^2)} > 7,\)

provided \(n ≠ 2\) or 4. However, \(s(4) > 0\) and so we conclude that

(6.6) \(\frac{[q^n](K(q) + 7M(q)) = |s(n)| \left( \frac{[q^n]K(q)}{|s(n)|} + 7\frac{s(n)}{|s(n)|} \right) > 0.\)

Next, we prove (6.3). Assume as before that \(n\) has the prime factorization,

\[n = 7^c 2^d \prod_{i=1}^r p_i^{v_i} \prod_{j=1}^s q_j^{w_j},\]

with \(p_i \equiv 1, 2, 4 \mod 7\), \(q_j \equiv 3, 5, 6 \mod 7\), \(b = \sum_{j=1}^s w_j\).

From (2.4) and (2.5), we find that

\([q^n] (L(q) - L(q^2) + K(q) - K(q^2)) = (7^c + (-1)^b)2^d \prod_{i=1}^r \frac{1 - p_i^{2v_i + 2}}{(1 - p_i^2)|F(p_i, v_i)|} \prod_{j=1}^s \frac{(-1)^{w_j} + q_j^{2w_j + 2}}{(1 + q_j^2)},\)

which proves (6.3) if \(s(n) = 0\). Next assume that \(s(n) ≠ 0\). Then, \(w_j\) and \(b\) are all even and by employing (2.7), (5.7), and (5.8), we find that

(6.7) \([q^n] (L(q) - L(q^2) + K(q) - K(q^2) - 2M(q))\)

(6.8) \(= |s(n)| \left( \frac{(7^c + 7^{-c})2^d}{|F(2, d)|} \prod_{i=1}^r \frac{1 - p_i^{2v_i + 2}}{(1 - p_i^2)|F(p_i, v_i)|} \prod_{j=1}^s \frac{1 + q_j^{2w_j + 2}}{q_j^{w_j}(1 + q_j^2)} \right) ≥ 0,\)

since \(|F(2, d)| ≤ (d + 1)2^d ≤ 2^{2d}\) by (5.6).
7. Concluding Remarks

We would like to point out that another upper bound for the coefficients of 7-cores is given by the inequality

\[ \left[ q^n \right] \left( \varphi^3(q) \varphi^3(q^7) \right) > 5 \left[ q^n \right] \left( q^3 \psi^3(q) \psi^3(q^7) \right) > \left[ q^n \right] \left( q^2 \frac{E^7(q^7)}{E(q)} \right) \]

for \( n \neq 2, 4, 7, 14, 22, 29, 58 \).

The proof of the first part of this inequality is similar to that of Theorem 1.1 and is omitted for space considerations. The second part of this inequality follows from Theorem 1.1. It would be interesting to prove all these inequalities for 7-cores in a completely elementary manner. It is natural to ask if our inequalities extend to general \( t \)-cores. We offer the following inequality as a conjecture:

\[ \left[ q^n \right] \left( \psi(q) \psi(q^t) \right)^{(t-1)/2} \geq \left[ q^n \right] \left( \frac{E^t(q^t)}{E(q)} \right), \]

valid for all \( n \), provided that \( t \) is an odd integer greater or equal to 11.

8. Acknowledgment

We would like to thank George Andrews, Frank Garvan, Michael Somos and James Sellers for their interest and helpful comments.
