The spectral gap of the 2-D stochastic Ising model with mixed boundary conditions

Preliminary Draft

Kenneth S. Alexander\textsuperscript{1} and Nobuo Yoshida\textsuperscript{2}

Abstract

We establish upper bounds for the spectral gap of the stochastic Ising model at low temperatures in an $l \times l$ box with boundary conditions which are not purely plus or minus; specifically, we assume the magnitude of the sum of the boundary spins over each interval of length $l$ in the boundary is bounded by $\delta l$, where $\delta < 1$. We show that for any such boundary condition, when the temperature is sufficiently low (depending on $\delta$), the spectral gap decreases exponentially in $l$.

1 Introduction

1.1 General background and heuristics

We begin with an informal description; full definitions will be given below. Consider the stochastic Ising model (Glauber dynamics) in an $l \times l$ box $\Lambda(l)$, below the critical temperature. At equilibrium, the typical configuration resembles one of the two infinite-volume pure phases (plus phase or minus phase) except very near the boundary. That is, the equilibrium distribution $\mu = \mu_{\Lambda(l),\omega}^\beta$ (at inverse temperature $\beta$, under boundary condition $\omega$) is roughly either the plus phase, the minus phase or a distributional mixture of the two. This equilibrium may take a long time to be reached, if the box is large. The rate of convergence is described by the spectral gap, denoted $\text{gap}(\Lambda(l),\omega,\beta)$, which is the smallest positive eigenvalue of the negative of the generator of the dynamics. More precisely, for $S(\cdot)$ the associated semigroup and $\| \cdot \|_\mu$ the $L^2(\mu)$ norm, $\text{gap}(\Lambda(l),\omega,\beta)$ is the largest constant $\Delta$ such that

$$\|S(t)f - \int f \, d\mu\|_\mu \leq \|f - \int f \, d\mu\|_\mu e^{-\Delta t} \quad \text{for all } f \in L^2(\mu) \text{ and } t \geq 0.$$ 

For pure boundary conditions, say all plus, at subcritical temperatures the spectral gap is believed to be of order $l^{-2}$ \cite{FH87}. The spectral gap can be very sensitive to the boundary condition, however. For example, removing as few as $O(\log l)$ plus spins near each corner of $\Lambda(l)$ (leaving the boundary there free, or minus) yields a gap much smaller than $l^{-2}$, and removing $\epsilon l$ plus spins from each corner, for some positive $\epsilon$, yields a gap which decreases exponentially in $l$ \cite{Al00}. These phenomena are outgrowths of the fact that the boundary conditions are not well mixed, the free boundary or minus spins being concentrated in short

intervals at the corners. More mixed boundary conditions are considered in [HY97], where it is shown that if the boundary condition $\omega$ satisfies

$$|\sum_{y \in I} \omega_y| \leq \delta l/2 \quad \text{for every interval } I \text{ in } \partial_{\text{ex}} \Lambda(l) \quad (1.1)$$

with $\delta < 1$, then

$$\text{gap}(\Lambda(l), \omega, \beta) \leq B_{1.2} \exp \left( -\beta l/C_{1.2} \right), \quad l = 1, 2, \ldots, \quad (1.2)$$

where $B_{1.2} = B_{1.2}(\beta) > 0$ and $C_{1.2} > 0$. Here $\partial_{\text{ex}} \Lambda(l)$ denotes the exterior boundary; see (1.8). One can allow the boundary spins $\omega_y$ to take values in the continuum $[-1, 1]$, with $\omega_y = 0$ representing the free boundary condition at site $y$. The condition (1.1) is somewhat restrictive, however; for example, it does not allow the long intervals of boundary plus spins which appear in the above-mentioned results from [Al00]. In this paper we establish (1.2) under a “mixed boundary” hypothesis much weaker than (1.1).

The importance of the geometry of boundary spin locations can be seen in comparing the result in [Al00], giving exponential decay of the gap when $\epsilon l$ plus spins are removed at each corner, to a result of Martinelli [Mar94] which states that when one side of the square has all-plus boundary condition, and the other 3 sides have free boundary, at sufficiently low temperatures one has

$$\exp \left( -C(\beta, \epsilon) l^{1/2 + \epsilon} \right) \leq \text{gap}(\Lambda(l), \omega, \beta) \quad \text{for } \epsilon > 0, \ l = 1, 2, \ldots. \quad (1.3)$$

In the latter case there are many fewer plus spins but the gap is much larger, meaning the convergence to the equilibrium plus phase is much faster.

The heuristics of the gap are rooted in the ideas of energy barriers and traps. From certain starting configurations, to reach a typical equilibrium configuration, one must pass through a set of configurations for each of which the total energy is greater than either the typical starting or equilibrium total energies. An energy barrier is such a set of high-energy configurations; the height of the barrier is the typical additional energy of the barrier configurations relative to the starting configurations. A trap is a set of starting configurations from which one cannot reach equilibrium without crossing an energy barrier. (We do not make formal definitions here, as we will not use these concepts other than descriptively.) Typically one expects the gap to be exponentially small in the height of the energy barrier that must be crossed, for a trap of which the probability is “not too small.” Often traps are related to the existence of macroscopic regions of the “wrong phase,” that is, say, regions of minus phase when the equilibrium is purely the plus phase. For example, in the “corners-removed” context of [Al00], a trap is formed by the configurations in which there is an “X” of minus phase connecting the four free-boundary corner regions, and the height of the associated energy barrier is proportional to the length of the corner regions. In the above “three-sides-free” example of Martinelli, however, say with the plus spins on the right side of the square, there is no real energy barrier because, starting from the minus phase, a region of plus phase can sweep leftward, maintaining an approximately vertical interface, until it covers the full square.
Consider now a boundary condition $\omega$ which is “well-mixed” in the sense that

$$|\sum_{y \in I} \omega_y| \leq \delta |I|$$  \hspace{1cm} (1.4)

for every “sufficiently long” interval $I$ in the boundary of $\Lambda(l)$, with $\delta < 1$, and suppose $\omega$ favors the plus phase (more precisely, the magnetization at the center of the square is nonnegative.) If the system is started entirely in the minus phase, we expect the region of minus phase (the “droplet”) to pull away from the boundary and then shrink to nothing, at which time equilibrium is essentially reached. When the droplet initially fills $\Lambda(l)$, the energy associated to its surface (this surface being essentially $\partial_{\text{ex}} \Lambda(l)$) is at most $8\delta l$, by (1.4). When the droplet has pulled only slightly away from the boundary, however, the surface energy becomes essentially twice the droplet boundary length (provided the temperature is very low), hence is at least about $8l$. Thus there is an energy barrier; the droplet will tend to stick to the boundary, meaning the minus phase is a trap. Though we do not make these particular heuristics rigorous in our proofs, they are what underlie our main result.

For fixed $\omega$ satisfying (1.4), at higher but still subcritical temperatures, one does not expect this phenomenon of sticking to the boundary to occur. This is because the surface energy (appropriately defined using surface tension and coarse-graining) of the droplet is no longer essentially twice its length; a diagonal interface has significantly less surface energy than combined horizontal and vertical interfaces having the same endpoints. This means the droplet should be able to pull away from the boundary, first from the corners, without the crossing of an energy barrier. We will not investigate this type of behavior here.

Additional existing results at subcritical temperatures include the following. Thomas [Tho89] proved that in general dimension $d$, for free boundary conditions ($\omega \equiv 0$), for sufficiently large $\beta$,

$$\text{gap}(\Lambda(l), \omega, \beta) \leq B_{1.5} \exp \left(-\beta l^{d-1}/C_{1.5}\right), \quad l = 1, 2, \cdots, \quad \text{(1.5)}$$

where $B_{1.5} = B_{1.5}(\beta, d) > 0$ and $C_{1.5} = C_{1.5}(d) > 0$. For $d = 2$, Cesi et al [CGMS96] prove (1.5) with $\omega \equiv 0$ for all $\beta > \beta_c$, where $\beta_c$ is the inverse critical temperature. For $d = 2$, in contrast with (1.5), it is known that for $\beta > \beta_c$ and $\omega \equiv +1$,

$$\exp(-\varphi(l)) \leq \text{gap}(\Lambda(l), \omega, \beta), \quad l = 1, 2, \cdots, \quad \text{(1.6)}$$

with a function $\varphi(l) = o(l^{1/2+\epsilon})$ as $l \to \infty$, for all $\epsilon > 0$. This result was first obtained by F. Martinelli [Mar94, Mar97]. More recently, Y. Higuchi and J. Wang [HW99] showed (1.6) with $\varphi(l) = C(\beta)(l \ln l)^{3/2}$. Schonmann [Sch94, Theorem 5] showed that $\text{gap}(\Lambda(l), \omega)$ can shrink no faster than exponential of $O(l^{d-1})$; specifically, the spectral gap has the following general lower bound for all $d \geq 2$ and $\beta > 0$:

$$q(\beta) l^{-d} \exp \left(-4\beta \sum_{j=0}^{d-1} l^j\right) \leq \inf_{\omega \in \Omega_h} \text{gap}(\Lambda(l), \omega, \beta), \quad l = 1, 2, \cdots, \quad \text{(1.7)}$$

Here $q(\beta)$ is a uniform lower bound for all flip rates.
1.2 Basic definitions

The lattice. For \( x = (x_1, x_2) \in \mathbb{Z}^2 \), we will use both the \( l_1 \)-norm \( \|x\|_1 = |x_1| + |x_2| \) and the \( l_\infty \)-norm \( \|x\|_\infty = \max\{|x_1|, |x_2|\} \). A set \( \Lambda \subset \mathbb{Z}^2 \) is said to be \( l_p \)-connected \((p = 1 \text{ or } \infty)\) if for each distinct \( x, y \in \Lambda \), we can find some \( \{x_0, \ldots, x_n\} \subset \Lambda \) with \( x_0 = x \), \( x_n = y \) and \( \|x_j - x_{j-1}\|_p = 1 \) \((j = 1, \ldots, n)\). The interior and exterior boundaries of a set \( \Lambda \subset \mathbb{Z}^2 \) will be denoted respectively by

\[
\partial_{\text{in}} \Lambda = \{ x \in \Lambda; \|x - y\|_1 = 1 \text{ for some } y \notin \Lambda \},
\]

\[
\partial_{\text{ex}} \Lambda = \{ y \notin \Lambda; \|x - y\|_1 = 1 \text{ for some } x \in \Lambda \}. \tag{1.8}
\]

The number of points contained in a set \( \Lambda \subset \mathbb{Z}^2 \) will be denoted by \(|\Lambda|\). We will use the notation \( \Lambda \subset \subset \mathbb{Z}^2 \) to indicate that \( \Lambda \subset \mathbb{Z}^2 \) with \(|\Lambda| < \infty\). A cube with the side-length \( l \) will be denoted by

\[
\Lambda(l) = (-l/2, l/2]^d \cap \mathbb{Z}^d. \tag{1.9}
\]

An \( l_\infty \)-connected subset of \( \partial_{\text{ex}} \Lambda(l) \) will be called an interval of \( \partial_{\text{ex}} \Lambda(l) \).

The configurations and the Gibbs states. We define two kind of spin configurations;

\[
\Omega_\Lambda = \{ \sigma = (\sigma_x)_{x \in \Lambda}; \sigma_x = +1 \text{ or } -1 \}; \ \Lambda \subset \subset \mathbb{Z}^2,
\]

\[
\Omega_\Omega = \{ \omega = (\omega_y)_{y \in \mathbb{Z}^2}; \omega_y \in [-1, 1] \}. \tag{1.10}
\]

We are mainly interested in \( \omega_y \in \{-1, 0, 1\} \), but there is no extra work in allowing \( \omega_y \in [-1, 1] \). We will refer an element \( \omega \) of \( \Omega_\Omega \) as a boundary condition. The set of all real functions on \( \Omega_\Lambda \) is denoted by \( \mathcal{C}_\Lambda \). For \( \Lambda \subset \subset \mathbb{Z}^2 \) and \( \omega \in \Omega_\Omega \), the Hamiltonian \( H^\omega_\Lambda : \Omega_\Lambda \to \mathbb{R} \) is defined by

\[
H^\omega_\Lambda (\sigma) = -\frac{1}{2} \sum_{\substack{x, y \in \Lambda \ 
\|x - y\|_1 = 1 \ 
\|y - x\|_1 = 1}} \sigma_x \sigma_y - \sum_{x \in \Lambda, y \notin \Lambda} \sigma_x \omega_y.
\]

A finite-volume Gibbs state on \( \Lambda \) with the boundary condition \( \omega \in \Omega_\Omega \) is defined to be a probability distribution \( \mu^\omega_\Lambda \) on \( \Omega_\Lambda \), in which the probability of each configuration \( \sigma \in \Omega_\Lambda \) is given by

\[
\mu^\omega_\Lambda (\{\sigma\}) = \frac{1}{Z^\omega_\Lambda} \exp -\beta H^\omega_\Lambda (\sigma),
\]

where \( \beta > 0 \) is the inverse temperature and \( Z^\omega_\Lambda \) is the normalizing constant.

Stochastic Ising Models. For \( \Lambda \subset \subset \mathbb{Z}^2 \), we consider a function \( q_\Lambda : \Lambda \times \Omega_\Lambda \times \Omega_\Omega \to [0, \infty[ \) which satisfies the following conditions;

(i) Boundedness : There exist positive constants \( q(\beta) \) and \( \overline{q}(\beta) \) such that

\[
q(\beta) \leq q_\Lambda(x, \sigma, \omega) \leq \overline{q}(\beta), \tag{1.10}
\]

for all \( \Lambda \subset \subset \mathbb{Z}^2 \), and \( (x, \sigma, \omega) \in \Lambda \times \Omega_\Lambda \times \Omega_\Omega \).
(ii) the Detailed Balance Condition:
\[ q_\Lambda(x, \sigma, \omega) \exp(-\beta H^\omega_\Lambda(\sigma)) = q_\Lambda(x, \sigma^\omega, \omega) \exp(-\beta H^\omega_\Lambda(\sigma^\omega)), \]
for all \( \Lambda \subset \subset \mathbb{Z}^2 \) and \( (x, \sigma, \omega) \in \Lambda \times \Omega \times \Omega_b \), where \( \sigma^\omega \) is the configuration obtained from \( \sigma \) by replacing \( \sigma_x \) by \(-\sigma_x\).

An example of such \( q_\Lambda(x, \sigma, \omega) \) is given by;
\[ q_\Lambda(x, \sigma, \omega) = \exp\left( -\beta \mathbb{E} \{ H^\omega_\Lambda(\sigma) \} \right) \]
\[ = \exp \left( -\beta \sigma_x \left\{ \sum_{y \in \Lambda : \|x-y\|_1 = 1} \sigma_y + \sum_{y \not\in \Lambda : \|x-y\|_1 = 1} \omega_y \right\} \right). \]

Now, fix \( \Lambda \subset \subset \mathbb{Z}^2 \) and \( \omega \in \Omega_b \). We define a linear operator \( A^\omega_\Lambda : C_\Lambda \to C_\Lambda \) by
\[ A^\omega_\Lambda f(\sigma) = \sum_{x \in \Lambda} q_\Lambda(x, \sigma, \omega) \{ f(\sigma^\omega) - f(\sigma) \}, \quad f \in C_\Lambda. \]

Thus \( q_\Lambda(x, \sigma, \omega) \) represents the rate at which the spin at \( x \) flips to the opposite spin, when the configuration is \( \sigma \). It can easily be seen from (1.11) that
\[ -\mu^\beta_{\Lambda, \omega}(f A^\omega_\Lambda g) = \frac{1}{2} \sum_{x \in \Lambda} \sum_{\sigma \in \Omega} \mu^\beta_{\Lambda, \omega}(\sigma) q_\Lambda(x, \sigma, \omega) \{ g(\sigma^\omega) - g(\sigma) \} \{ f(\sigma^\omega) - f(\sigma) \}. \]

Next, we define
\[ \text{gap}(\Lambda, \omega, \beta) = \inf \left\{ \frac{-\mu^\beta_{\Lambda, \omega}(f A^\omega_\Lambda f)}{\mu^\beta_{\Lambda, \omega}(|f - \mu^\beta_{\Lambda, \omega} f|)} : f \in C_\Lambda \right\}, \]
which is the smallest positive eigenvalue of \(-A^\omega_\Lambda\). Considering only indicator functions in (1.13) we obtain
\[ \text{gap}(\Lambda, \omega, \beta) \leq \frac{\mathcal{Q}(\beta)}{\mu^\beta_{\Lambda(l), \omega}(\Gamma) \mu^\beta_{\Lambda(l), \omega}(\Gamma^c)} \sum_{x \in \Lambda(l)} \sum_{\sigma \in \Gamma: \sigma \not\in \Gamma} \mu^\beta_{\Lambda(l), \omega}(\sigma). \]

Thus any fixed event \( \Gamma \) gives an upper bound for the gap. Roughly, to obtain a good bound one wants to choose \( \Gamma \) to be a trap.

1.3 Statement of main results

The following is our main result, improving on the condition (1.1).

**Theorem 1.1** Consider a stochastic Ising model on a square \( \Lambda(l) \) satisfying (1.10) and (1.11). Suppose that \( 0 < \delta < 1 \) and the boundary condition \( \omega_y \in [-1, +1], y \in \partial_\infty \Lambda(l) \) satisfies
\[ |\sum_{y \in I} \omega_y| \leq \delta |I| \] for every interval \( I \subset \partial_\infty \Lambda(l) \) with \( |I| = l \).

Then, there exists \( \beta_0 = \beta_0(\delta) > 0 \) such that
\[ \text{gap}(\Lambda(l), \omega, \beta) \leq B_{1.16} \exp(-\beta l/C_{1.16}), \]
for \( \beta \geq \beta_0 \) and \( l = 1, 2, \ldots \), where \( B_{1.16} = B_{1.16}(\beta, \delta) > 0 \) and \( C_{1.16} = C_{1.16}(\delta) > 0 \).
Condition (1.15) is much milder than (1.1). For example, (1.15) allows a boundary condition which is +1 for 99 % of the boundary with 1 % zero on each side. Moreover, condition (1.15) turns out to be optimal in the following example. For \( \delta > 0 \), consider a boundary condition

\[
\omega_x = \begin{cases} 
+1 & \text{if } x_1 = \lfloor l/2 \rfloor + 1 \text{ and } -\frac{\delta l}{2} < x_2 \leq \frac{\delta l}{2}, \\
0 & \text{otherwise.}
\end{cases}
\]

(1.17)

In this example, we see the transition from (1.2) to (1.3) depending on the value of \( \delta \). By Theorem 1.1, one sees that (1.2) is true for all \( \delta < 1 \). On the other hand, it follows from [Mar94, Corollary 4.1] that (1.3) holds true for \( \delta = 1 \).

Theorem 1.1 has the following application to random boundary conditions.

**Corollary 1.2** Suppose that \( d = 2 \) and that \( \omega_y \in [-1, 1] \), \( y \in \mathbb{Z}^2 \) are i.i.d. random variables with the mean \( m \in (-1, 1) \). Then, there exists \( \beta_0 = \beta_0(m) > 0 \) as follows. For \( \beta \geq \beta_0 \), there are constants \( B_{1.18} = B_{1.18}(\beta, m) > 0 \) and \( C_{1.18} = C_{1.18}(m) > 0 \) such that almost surely;

\[
\text{gap}(\Lambda(l), \omega, \beta) \leq B_{1.18} \exp(-\beta l/C_{1.18}) \quad \text{for } l = 1, 2, \ldots
\]

(1.18)

Proof of Corollary 1.2 is similar to that of [HY97, Corollary 2.2.] and hence is omitted.

2 Preliminaries for the proof of Theorem 1.1

2.1 Contours

The set \( B \) of all bonds in \( \mathbb{Z}^2 \) is defined by

\[
B = \{ \{x, y\} \subset \mathbb{Z}^2 ; \|x - y\|_1 = 1 \}.
\]

For a set \( \Lambda \), we define

\[
B_\Lambda = \{ \{x, y\} \in B ; (x, y) \in \Lambda^2 \},
\]

\[
\partial B_\Lambda = \{ \{x, y\} \in B ; (x, y) \in \Lambda \times \Lambda^c \},
\]

\[
\overline{B}_\Lambda = B_\Lambda \cup \partial B_\Lambda.
\]

The dual lattice \( (\mathbb{Z}^2)^* \) is \( \mathbb{Z}^2 \) shifted by \( (\frac{1}{2}, \frac{1}{2}) \); sites and bonds of this lattice are called dual sites and dual bonds. \( x^* \) denotes \( x + (\frac{1}{2}, \frac{1}{2}) \). When necessary for clarity, bonds of \( \mathbb{Z}^2 \) are called regular bonds. To each regular bond \( b \) there is associated a unique dual bond \( b^* \) which is its perpendicular bisector. For \( A \subset B \) we write \( A^* \) for \( \{ e^* : e \in A \} \). For \( \gamma \subset \overline{B}_\Lambda \) we set

\[
V(\gamma) = \cup_{e = \{x, y\}: x^* \in \gamma} \{x, y\}, \quad V_{\text{ex}}(\gamma) = V(\gamma) \cap \partial_{\text{ex}} \Lambda.
\]

When convenient we view bonds and dual bonds as closed intervals in \( \mathbb{R}^2 \), as when referring to a connected set of (dual) bonds. The number of dual bonds contained in a set \( \gamma \subset B^* \) will be denoted by \( |\gamma| \).
For \( x \in \mathbb{R}^2 \) let \( Q(x) = \prod_{j=1}^{2} [x_j - \frac{1}{2}, x_j + \frac{1}{2}] \), and for \( \Theta \subset \mathbb{Z}^2 \) let \( Q(\Theta) = \cup_{x \in \Theta} Q(x) \). A contour is a finite subset \( \gamma \subset \mathbb{B} \) which is of the form \( \partial Q(\Theta) \) for some finite \( \Theta \subset \mathbb{Z}^2 \) for which both \( \Theta \) and \( \Theta^c \) are \( l_1 \)-connected. The set \( \Theta \) is uniquely determined by \( \gamma \) and hence is denoted by \( \Theta(\gamma) \). As is well known, for each \( b \in \mathbb{B} \) and \( m = 1, 2, \cdots \),

\[
\sharp \{ \gamma : \gamma \text{ is a contour with } |\gamma| = m \text{ and } \gamma \ni b \} \leq 3^{m-1}.
\] (2.1)

If a contour \( \gamma \) is a subset of \( \overline{\mathbb{B}}_l \) for some \( \Lambda \subset \mathbb{Z}^2 \), we say \( \gamma \) is a contour in \( \Lambda \). For \( \sigma \in \Omega_{\Lambda} \), \( \varepsilon = + \) or \( - \) and \( \Lambda \subset \mathbb{Z}^2 \), an \((\varepsilon)\)-cluster in \( \Lambda \) at \( \sigma \) is an \( l_1 \)-connected component of \( \{ x \in \mathbb{Z}^2 : \sigma_x = \varepsilon \} \). The outer boundary of a bounded subset \( A \) of \( \mathbb{R}^2 \) is the unique connected component of \( \partial A \) which is contained in the closure of the unique unbounded component of \( \Lambda^c \). A contour \( \gamma \) is said to be an \((\varepsilon)\)-contour in \( \Lambda \) at \( \sigma \) if \( \gamma \) is the outer boundary of \( Q(\Theta) \) for some \((\varepsilon)\)-cluster \( \Theta \). A contour \( \gamma \) is said to be a contour in \( \Lambda \) at \( \sigma \in \Omega_{\Lambda} \) if it is either \((+\varepsilon)\)-contour in \( \Lambda \) at \( \sigma \) or \((-\varepsilon)\)-contour in \( \Lambda \) at \( \sigma \). Note that the boundary condition does not affect whether a given \( \gamma \) is an \((\varepsilon)\)-contour in \( \Lambda \), under our definition.

### 2.2 Reductions

We may assume slightly more restrictive condition than (1.15) to prove Theorem 1.1.

First, we may replace (1.15) with

\[
|\sum_{y \in I} \omega_y| \leq \delta_{2.2} |I| \quad \text{for every interval } I \subset \partial_{ex} A(l) \text{ with } |I| \geq l.
\] (2.2)

This is because (1.15) for a given \( \delta \) implies (2.2) with \( \delta_{2.2} = (1 + \delta)/2 \). We may next strengthen (2.2) as follows: there exists \( 0 < \delta_{2.3} < 1 \) such that

\[
|\sum_{y \in I} \omega_y| \leq \delta_{2.3} |I| \quad \text{for every interval } I \subset \partial_{ex} A(l) \text{ with } |I| \geq \delta_{2.3} |l|.
\] (2.3)

In fact, suppose that the boundary condition \( \omega \) satisfies (2.2) for some \( \delta < 1 \). Let \( \tilde{\delta} < 1 \) satisfy

\[
\delta + (1 + \delta)(1 - \tilde{\delta})\tilde{\delta}^{-1} < \tilde{\delta} < 1.
\] (2.4)

Then (2.3) with \( \delta_{2.3} = \tilde{\delta} \) holds. To see this, take an arbitrary interval \( I \subset \partial_{ex} A(l) \) with \( |I| \geq \delta |l| \). By expanding \( I \), if necessary, we get an interval \( \tilde{I} \supset I \) such that \( |\tilde{I}| \geq l \) and \( |\tilde{I} \setminus I| \leq (1 - \tilde{\delta})l \leq (1 - \tilde{\delta})\tilde{\delta}^{-1} |I| \). We then have \( |\tilde{I}| \leq (1 + (1 - \tilde{\delta})\tilde{\delta}^{-1}) |I| \), so

\[
\frac{\omega_y}{|I|} \leq \omega_y + (1 - \tilde{\delta})\tilde{\delta}^{-1} |I|, \leq \delta I + (1 - \tilde{\delta})\tilde{\delta}^{-1} |I| \leq \tilde{\delta} |I|.
\]
2.3 Outline of the proof of Theorem 1.1

We may and will assume (2.3). The basic strategy to prove Theorem 1.1 is rather standard [Tho89, HY97]. We define an event $\Gamma_l \subset \Omega_{\Lambda(l)}$ in which a “large” contour is present; by (1.14),

$$\text{gap}(\Lambda(l), \omega, \beta) \leq \frac{\eta(\beta)}{\mu^\beta_{\Lambda(l), \omega}(\Gamma_l)} \sum_{x \in \Lambda(l)} \sum_{\sigma \in \Gamma_l : \sigma \not\in \Gamma_l} \mu^\beta_{\Lambda(l), \omega}(\sigma).$$

To prove Theorem 1.1, we will show that for large $\beta$, $\mu^\beta_{\Lambda(l), \omega}(\Gamma_l)$ is uniformly positive in $l$ (Lemma 2.1 below) and

$$\mu^\beta_{\Lambda(l), \omega}(\Gamma_l)^{-1} \sum_{x \in \Lambda(l)} \sum_{\sigma \in \Gamma_l : \sigma \not\in \Gamma_l} \mu^\beta_{\Lambda(l), \omega}(\sigma)$$

is exponentially small in $l$ (Lemma 2.2 below).

To define $\Gamma_l$, we choose $\epsilon_{l, \omega} = \pm$ as follows;

$$\epsilon_{l, \omega} = \begin{cases} + & \text{if } \mu^\beta_{\Lambda(l), \omega}(\sigma_0) \geq 0, \\ - & \text{if } \mu^\beta_{\Lambda(l), \omega}(\sigma_0) < 0. \end{cases}$$

We fix $\delta_1$ such that $0 < \delta_1 < 1$. The event $\Gamma_l$ is defined by

$$\Gamma_l = \{ \sigma \in \Omega_{\Lambda(l)} : C_l(\sigma) \neq \emptyset \},$$

where

$$C_l(\sigma) = \{ \gamma : \gamma \text{ is an } (\epsilon_{l, \omega})\text{-contour in } \Lambda(l) \text{ at } \sigma \text{ such that } \gamma \cap \partial \Omega(\Lambda(l)) \neq \emptyset \text{ and } |\gamma| \geq 2\delta_1 l \}.\$$

To bound (2.3) from above, we use the following two lemmas.

**Lemma 2.1** Assume (2.2). There exists $\beta_1 = \beta_1(\delta_{2.3}) > 0$ such that

$$\inf_{l \geq 1} \mu^\beta_{\Lambda(l), \omega}(\Gamma_l) \geq \frac{1}{2} \text{ for } \beta \geq \beta_1.$$  

(2.9)

**Lemma 2.2** Assume (2.2). There exists $\beta_2 = \beta_2(\delta_{2.3}) > 0$ such that

$$\sum_{x \in \Lambda(l)} \sum_{\sigma \in \Gamma_l : \sigma \not\in \Gamma_l} \mu^\beta_{\Lambda(l), \omega}(\sigma) \leq \mu^\beta_{\Lambda(l), \omega}(\Gamma_l) B_{2.10} \exp\left(-\beta l/C_{2.10}\right)$$

for $\beta \geq \beta_2$ and $l = 1, 2, \ldots$, where $B_{2.10} = B_{2.10}(\beta, \delta_{2.3}) > 0$ and $C_{2.10} = C_{2.10}(\delta_{2.3}) > 0.$

Theorem 1.1 follows immediately by plugging (2.9) and (2.10) into (2.5). In fact, we have for $\beta \geq \max\{\beta_1, \beta_2\}$ that

$$\text{gap}(\Lambda(l), \omega, \beta) \leq 3\eta(\beta) B_{2.10} \exp\left(-\beta l/C_{2.10}\right).$$

(2.11)

$\square$
3 Proof of Lemmas 2.1 and 2.2

3.1 Energy estimates for contours

The proofs of Lemma 2.1 and Lemma 2.2 are based on energy estimates for contours, which we present in this subsection. We have to introduce additional definitions. The right, left, top and bottom sides of the square $Q(\Lambda(l))$ are denoted by $F_l^+, F_l^-, F_l^+, F_l^-$. A set of dual bonds $\gamma \subset B_\Lambda^*$ is said to be horizontally crossing if

$$A \cap F_l^1 \neq \emptyset \text{ and } A \cap F_l^{-1} \neq \emptyset.$$  \hfill (3.1)

Similarly, $\gamma$ is said to be vertically crossing if

$$A \cap F_l^2 \neq \emptyset \text{ and } A \cap F_l^{-2} \neq \emptyset.$$  \hfill (3.2)

The set $A$ is said to be crossing if it is either horizontally crossing or vertically crossing.

Suppose that $\gamma_1, \ldots, \gamma_p$ are contours in $\Lambda(l)$. We set

$$\Delta_{\gamma_1, \ldots, \gamma_p} H_{\Lambda(l)}^\omega(\sigma) = H_{\Lambda(l)}^\omega(\sigma) - H_{\Lambda(l)}^\omega(T_{\gamma_1} \circ \cdots \circ T_{\gamma_p} \sigma), \quad \sigma \in \Omega_{\Lambda(l)}$$  \hfill (3.3)

where we have defined a map $T_{\gamma} : \Omega_{\Lambda(l)} \to \Omega_{\Lambda(l)}$ for a contour $\gamma$ by

$$(T_{\gamma}\sigma)_x = \begin{cases} -\sigma_x, & \text{if } x \in \Theta(\gamma) \\ \sigma_x, & \text{if } x \notin \Theta(\gamma). \end{cases}$$  \hfill (3.4)

Suppose that a contour $\gamma$ is non-crossing. Then $\gamma \cap (F_i^1 \cup F_i^-) = \emptyset$ for some $i, j$ with $|i| = 1$ and $|j| = 2$. Then there exists a unique connected component $\gamma$ of $\gamma \setminus \partial Q(\Lambda(l))$ which divides $\Lambda(l)$ into two $l_1$-connected components $\tilde{\Theta}$ and $\Lambda(l) \setminus \tilde{\Theta}$ such that $\Theta(\gamma) \subset \tilde{\Theta}$ and $F_i^1 \cup F_i^- \subset \partial Q(\Lambda(l) \setminus \tilde{\Theta})$. We define $\gamma \subset \partial Q(\Lambda(l))$ and the interval $I(\gamma) \subset \partial_{\textrm{ex}} \Lambda(l)$ respectively by

$$\gamma = \partial Q(\Lambda(l)) \cap \partial Q(\tilde{\Theta}),$$  \hfill (3.5)

$$I(\gamma) = \text{Vex}(\gamma).$$  \hfill (3.6)

Note that

$$\gamma \supset \gamma \cap \partial Q(\Lambda(l)).$$  \hfill (3.7)

Note also that bonds in $\gamma$ are in one-to-one correspondence with sites in $I(\gamma)$ in an obvious way.

**Lemma 3.1 a)** Let $\gamma$ be a non-crossing $(\epsilon)$-contour at a configuration $\sigma \in \Omega_{\Lambda(l)}$. Then

$$|\gamma \setminus \partial Q(\Lambda(l))| \geq \frac{1}{2} |\gamma| + \frac{1}{2} |\gamma \setminus \partial Q(\Lambda(l)) \cup \gamma|,$$  \hfill (3.8)

$$\frac{1}{2} \Delta_{\gamma} H_{\Lambda(l)}^\omega(\sigma) \geq \frac{1}{2} |\gamma| + \frac{1}{2} |\gamma \setminus \partial Q(\Lambda(l)) \cup \gamma| - \epsilon \sum_{y \in \text{Vex}(\gamma)} \omega_y,$$  \hfill (3.9)

$$\frac{1}{2} \Delta_{\gamma} H_{\Lambda(l)}^\omega(\sigma) \geq |\gamma| - \epsilon \sum_{y \in \text{Vex}(\gamma \setminus \gamma)} \omega_y \geq 0.$$  \hfill (3.10)
b) Suppose \( \{\gamma_j\}_{j=1}^p \) are \((\epsilon)\)-contours in \( \Lambda(l) \) at \( \sigma \) such that

\[
\frac{1}{2} \Delta_{\gamma_1, \ldots, \gamma_p} H_{\Lambda(l)}^\omega(\sigma) \geq c_1 l - c_2 \quad \text{for some } c_i \geq 0 \quad (i = 1, 2).
\]

Then,

\[
\frac{1}{2} \Delta_{\gamma_1, \ldots, \gamma_p} H_{\Lambda(l)}^\omega(\sigma) \geq \frac{c_1}{c_1 + 8} \sum_{j=1}^p |\gamma_j| - c_2.
\]

(c) Let \( \gamma, \gamma_1, \ldots, \gamma_p \) be non-crossing \((\epsilon)\)-contours at a configuration \( \sigma \in \Omega_{\Lambda(l)} \). Suppose that condition (2.3) is satisfied and that \( I \) is an interval in \( \partial_{\text{ex}} \Lambda(l) \) such that

\[
\bigcup_{j=1}^p I(\gamma_j) \subset I,
\]

\[
\delta_{2.3} l \leq |I| \leq \sum_{j=1}^p |\gamma_j| + c,
\]

where \( c \geq 0 \) is a constant. Then

\[
\frac{1}{2} \Delta_{\gamma_1, \ldots, \gamma_p} H_{\Lambda(l)}^\omega(\sigma) \geq \varepsilon_{3.15} \max\{l, \sum_{j=1}^p |\gamma_j|\} - c,
\]

where the constant \( \varepsilon_{3.13} > 0 \) depends only on \( \delta_{2.3} \).

Proof of part (a): We have the following relations:

\[
\frac{1}{2} \Delta_{\gamma} H_{\Lambda(l)}^\omega(\sigma) = |\gamma \setminus \partial Q(\Lambda(l))| - \epsilon \sum_{y \in V_{\text{ex}}(\gamma)} \omega_y,
\]

\[
|I(\gamma)| = |\gamma| \leq |\gamma|,
\]

\[
|\gamma \setminus \gamma| \leq |\gamma \setminus (\partial Q(\Lambda(l)) \cup \gamma)|.
\]

The equality (3.16) is obvious. The inequalities (3.17) and (3.18) can be seen from geometric considerations as follows. We decompose \( \gamma \setminus \partial Q(\Lambda(l)) \) into connected components \( \{\lambda_i\}_{i \geq 0} \), where \( \lambda_0 = \gamma \). Let \( \tau_0 = \gamma \) and let \( \{\tau_i\}_{i \geq 1} \) be connected components of \( \gamma \setminus \gamma \). We can arrange the enumeration so that \( \lambda_i \) and \( \tau_i \) have common endpoints for each \( i \geq 0 \). From this observation and the fact that \( \gamma \) is non-crossing, it follows that \( |\lambda_i| \geq |\tau_i| \) for each \( i \geq 0 \). In particular, \( |\lambda_0| \geq |\tau_0| \) and \( \sum_{i \geq 1} |\tau_i| \leq \sum_{i \geq 1} |\lambda_i| \) which prove, respectively, (3.17) and (3.18). By (3.7) and (3.17), we have that \( |\gamma| \geq |\gamma \cap \partial Q(\Lambda(l))| \) and hence that

\[
2|\gamma \setminus \partial Q(\Lambda(l))| \geq 2|\gamma| + 2|\gamma \setminus (\partial Q(\Lambda(l)) \cup \gamma)|
\]

\[
\geq |\gamma| + |\gamma \cap \partial Q(\Lambda(l))| + 2|\gamma \setminus (\partial Q(\Lambda(l)) \cup \gamma)|
\]

\[
= |\gamma| + |\gamma \setminus (\partial Q(\Lambda(l)) \cup \gamma)|.
\]

This proves (3.8), which together with (3.16) implies (3.9).
On the other hand, we have by (3.18) that $|\nabla \gamma| \leq |\gamma \setminus \partial Q(\Lambda(l))| - |\gamma|$ and hence that

$$
| \sum_{y \in V_{ex}(\gamma)} \omega_y - \sum_{y \in I(\gamma)} \omega_y | = | \sum_{y \in V_{ex}(\nabla \gamma)} \omega_y |
\leq |\gamma \setminus \partial Q(\Lambda(l))| - |\gamma|.
$$

(3.19)

The inequality (3.10) follows from (3.16) and (3.19).

Proof of part (b): Let $\alpha = 1/(c_1 + 8)$.

Case 1: $\alpha \sum_{j=1}^p |\gamma_j| \leq l$. In this case, we obviously have that

$$
\frac{1}{2} \Delta_{\gamma_1, \ldots, \gamma_p} H_{\Lambda(l)}^\omega(\sigma) \geq c_1 \alpha \sum_{j=1}^p |\gamma_j| - c_2.
$$

Case 2: $\alpha \sum_{j=1}^p |\gamma_j| \geq l$. In this case,

$$
\frac{1}{2} \Delta_{\gamma_1, \ldots, \gamma_p} H_{\Lambda(l)}^\omega(\sigma) \geq \sum_{j=1}^p (|\gamma_j| - |I(\gamma_j)|)
\geq |I| - \sum_{j=1}^p |I(\gamma_j)| - c
\geq (1 - \delta_1)|I| - c
\geq (1 - \delta_1)\delta_{2.3}l - c.
$$

Therefore (3.12) follows.

Proof of part (c): It is enough to prove (3.11) with some $c_1 > 0$ and $c_2 = c$. Recall that $\delta_{2.3} < \delta_1 < 1$.

Case 1: $\sum_{j=1}^p |I(\gamma_j)| \leq \delta_1|I|$. In this case,

$$
\frac{1}{2} \Delta_{\gamma_1, \ldots, \gamma_p} H_{\Lambda(l)}^\omega(\sigma) \geq \sum_{j=1}^p (|\gamma_j| - |I(\gamma_j)|)
\geq |I| - \sum_{j=1}^p |I(\gamma_j)| - c
\geq (1 - \delta_1)|I| - c
\geq (1 - \delta_1)\delta_{2.3}l - c,
$$

which implies (3.11) with $c_1 = (1 - \delta_1)\delta_{2.3}$.

Case 2: $\sum_{j=1}^p |I(\gamma_j)| \geq \delta_1|I|$. We set $A = I \setminus \bigcup_{j=1}^p I(\gamma_j)$ so that $|A| \leq (1 - \delta_1)|I|$. We then have by (3.10), (3.14), (2.3) that

$$
\frac{1}{2} \Delta_{\gamma_1, \ldots, \gamma_p} H_{\Lambda(l)}^\omega(\sigma) \geq \sum_{j=1}^p \left(|\gamma_j| - \epsilon \sum_{y \in I(\gamma_j)} \omega_y\right)
\geq |I| - \epsilon \sum_{y \in I(\gamma_j)} \omega_y - |A|
\geq |I| - \epsilon \sum_{y \in I} \omega_y - |A|
\geq |I| - \epsilon \sum_{y \in I} \omega_y - |A|
\geq \delta_1 - \delta_{2.3}l - c,
$$

which implies (3.11) with $c_1 = (\delta_1 - \delta_{2.3})\delta_{2.3}$. □
Lemma 3.2 Let $\gamma$ be an $\epsilon$- contour in $\Lambda(l)$ at a configuration $\sigma$.

a) If $\gamma$ intersects with exactly one of the sides $F_1^j$ ($j = \pm 1, \pm 2$), then

$$\Delta_\gamma H_{\Lambda(l)}^\omega(\sigma) \geq \begin{cases} |\{\text{horizontal bonds in } \gamma\}| & \text{if } j = \pm 1, \\ |\{\text{vertical bonds in } \gamma\}| & \text{if } j = \pm 2. \end{cases}$$

(3.20)

b) If $\Theta(\gamma) \ni \emptyset$ and $|\gamma| < 2l$, then

$$\Delta_\gamma H_{\Lambda(l)}^\omega(\sigma) \geq 2|\gamma|/9.$$  

(3.21)

Proof of part (a): Suppose for example that $\gamma$ intersects only with $F_1^1$. Then,

$$|\gamma \cap F_1^1| \leq |\{\text{vertical bonds in } \gamma \setminus \partial \Lambda(l)\}|.$$  

Therefore,

$$\frac{1}{2} \Delta_\gamma H_{\Lambda(l)}^\omega(\sigma) \geq |\{\text{horizontal bonds in } \gamma\}| + |\{\text{vertical bonds in } \gamma \setminus \partial \Lambda(l)\}| - |\gamma \cap F_1^1| \geq |\{\text{horizontal bonds in } \gamma\}|.$$  

Proof of part (b): If $\gamma \cap \partial \Lambda(l) = \emptyset$, then (3.21) is obvious. We therefore assume that $\gamma \cap \partial \Lambda(l) \neq \emptyset$. Since $0 \in \Theta(\gamma)$ and $|\gamma| < 2l$, $\gamma$ must intersect with exactly one of $F_1^j$ ($j = \pm 1, \pm 2$). Therefore, we see from (3.20) that $\frac{1}{2} \Delta_\gamma H_{\Lambda(l)}^\omega(\sigma) \geq l$, which implies (3.21) by Lemma 3.1. □

3.2 Proof of Lemma 2.1

We have that

$$\mu_{\Lambda(l),\omega}^\beta(\Gamma_l) \geq \mu_{\Lambda(l),\omega}^\beta(\{\sigma_0 = \epsilon_{l,\omega} 1\} \cap \Gamma_l)$$  

$$= \mu_{\Lambda(l),\omega}^\beta(\{\sigma_0 = \epsilon_{l,\omega} 1\}) - \mu_{\Lambda(l),\omega}^\beta(\{\sigma_0 = \epsilon_{l,\omega} 1\} \cap \Gamma_l^c)$$  

$$\geq \frac{1}{2} - \mu_{\Lambda(l),\omega}^\beta(\{\sigma_0 = \epsilon_{l,\omega} 1\} \cap \Gamma_l^c).$$

(3.22)

At a configuration $\sigma \in \{\sigma_0 = \epsilon_{l,\omega} 1\} \cap \Gamma_l^c$, the point 0 is enclosed by a ($\epsilon_{l,\omega}$)-contour $\gamma$ such that either $\gamma \cap \partial Q(\Lambda(l)) = \emptyset$ or $|\gamma| < 2\delta_1 l$. If $\gamma \cap \partial Q(\Lambda(l)) = \emptyset$, then

$$\Delta_\gamma H_{\Lambda(l)}^\omega(\sigma) = 2|\gamma|.$$  

If otherwise, $\gamma$ satisfies the condition for (3.21). We therefore have in both cases

$$\Delta_\gamma H_{\Lambda(l)}^\omega(\sigma) \geq 2|\gamma|/9.$$
By the standard Peierl’s argument,
\[
\mu^\beta_{\Lambda(l),\omega}(\{\sigma_0 = \epsilon_{t,\omega}1 \cap \Gamma_1\}) \leq \sum_\gamma \mu^\beta_{\Lambda(l),\omega}\{\Delta_x \tilde{H}_{\Lambda(l)}(\sigma) \geq 2|\gamma|/9\} \leq \sum_\gamma \exp(-2\beta|\gamma|/9),
\]
where \(\sum_\gamma\) stands for summation over all contours \(\gamma\) which satisfies \(\Theta(\gamma) \ni 0\). By using the counting inequality \((2.1)\), we see that
\[
\lim_{\beta \to \infty} \sum_\gamma \exp(-2\beta|\gamma|/9) = 0,
\]
which, together with \((3.22)\) and \((3.23)\), implies Lemma 2.1. \(\square\)

### 3.3 Proof of Lemma 2.2

We may assume that \(\epsilon_{t,\omega} = +\).

Step 1: Suppose that \(\sigma \in \Gamma_l\) and \(\sigma^x \not\in \Gamma_l\) for some \(x \in \Lambda(l)\). We consider two cases separately at first: \(\sigma_x = 1\) and \(\sigma_x = -1\).

Consider first \(\sigma_x = 1\). Let \(\gamma\) be the outer boundary of the (+)-cluster at \(\sigma\) which contains \(x\). The way the transition from \(\sigma \in \Gamma_l\) to \(\sigma^x \not\in \Gamma_l\) occurs is that the set \(C_l(\sigma)\) contains only the one element \(\gamma\), and the flipping of \(\sigma_x\) shortens \(\gamma\) or separates \(\gamma\) from \(\partial Q(\Lambda(l))\) or makes \(\gamma\) break into new shorter contours. Some of these shorter contours may include dual bonds which were not part of \(\gamma\) at \(\sigma\), but rather were part of \(\gamma\)-contours inside \(\gamma\) at \(\sigma\). We have then
\[
C_l(\sigma) = \{\gamma\}, \quad (3.24)
\]
\[
x \text{ is in or adjacent to } V(\gamma); \quad (3.25)
\]
in fact if either \((3.24)\) or \((3.25)\) fails, then \(C_l(\sigma) = C_l(\sigma^x)\), contradicting our assumption that \(\sigma \in \Gamma_l\) and \(\sigma^x \not\in \Gamma_l\). Further, there are \((\alpha)-\text{contours } \gamma_1,\ldots,\gamma_m\) and \(\gamma'_1,\ldots,\gamma'_n\) \((m \geq 0, n \geq 0, 1 \leq m+n \leq 4)\) at the flipped configuration \(\sigma^x\), and \((\beta)-\text{contours } \alpha_1,\ldots,\alpha_k\) \((0 \leq k \leq 2)\) inside \(\gamma\) at \(\sigma\), such that
\[
\gamma_j \cap \partial Q(\Lambda(l)) \neq \emptyset, \quad |\gamma_j| < 2\delta l, \quad \text{for } j = 1,\ldots,m, \quad (3.26)
\]
\[
\gamma'_j \cap \partial Q(\Lambda(l)) = \emptyset, \quad \text{for } j = 1,\ldots,n, \quad (3.27)
\]
\[
\left(\gamma \cup \left(\bigcup_{j=1}^m \alpha_j\right)\right) \Delta \left(\left(\bigcup_{j=1}^m \gamma_j\right) \cup \left(\bigcup_{j=1}^n \gamma'_j\right)\right) \subset \partial Q(x), \quad (3.28)
\]
\[
\Theta(\gamma) \Delta \left(\left(\bigcup_{j=1}^m \Theta(\gamma_j)\right) \cup \left(\bigcup_{j=1}^n \Theta(\gamma'_j)\right) \cup \left(\bigcup_{j=1}^k \Theta(\alpha_j)\right)\right) = \{x\}, \quad (3.29)
\]
where \(\Delta\) stands for the symmetric difference of two sets. Each \(\alpha_j, \gamma_j\) and \(\gamma'_j\) must surround at least one neighbor of \(x\). \(\gamma_1,\ldots,\gamma_m\) and \(\gamma'_1,\ldots,\gamma'_n\) are precisely the \((\alpha)-\text{contours } \sigma_x\) which include bonds of \(\gamma\). Let
\[
S_- = \sum_{j=1}^m |\gamma_j| + \sum_{j=1}^n |\gamma'_j|, \quad S_+ = |\gamma| + \sum_{j=1}^k |\alpha_j|.
\]
Using (3.28) it is easy to see that

\[ S_+ \leq S_- \leq S_+ + 4. \]  

(3.30)

We will show that

\[ \Delta_{\gamma,\alpha_1,\ldots,\alpha_k} H_{\Lambda(l)}^\omega(\sigma) \geq \varepsilon_{3.31} S_+ - C_{3.31}, \]  

(3.31)

where \( \varepsilon_{3.31} = \varepsilon_{4.3}(\delta) > 0 \) and \( C_{3.31} = C_{3.31}(\delta) > 0 \), by using (3.28) and studying the contours \( \gamma_1, \ldots, \gamma_m \) and \( \gamma_1', \ldots, \gamma_n' \).

Now consider \( \sigma_x = -1 \). In this case, one possibility is that the flipping of \( \sigma_x \) connects together two or three (+)-clusters to create a (+)-cluster which has a shorter outer boundary than the longest of the original (+)-clusters had. If we let \( \gamma \) denote the outer boundary of the (+)-cluster of \( x \) at \( \sigma^x \), this means there are again (+)-contours \( \gamma_1, \ldots, \gamma_m \) and \( \gamma_1', \ldots, \gamma_n' \) \( (m \geq 0, n \geq 0, 1 \leq m + n \leq 2) \), and (-)-contours \( \alpha_1, \ldots, \alpha_k \) \( (0 \leq k \leq 2) \) inside \( \gamma \), such that (3.27)–(3.29) hold, but now \( \gamma \) and the \( \alpha_j \) exist at \( \sigma^x \) and the \( \gamma_j \) and \( \gamma_j' \) exist at \( \sigma \). Further, \( |\gamma| \leq 2\delta_1 l \), and in place of (3.26),

\[ \gamma_j \cap \partial Q(\Lambda(l)) \neq \emptyset, \quad \text{for } j = 1, \ldots, m, \quad |\gamma_j| \geq 2\delta_1 l \quad \text{for some } j. \]  

(3.32)

(The other possibility when \( \sigma_x = -1 \) is that only one (+)-cluster (call it \( C \)) at \( \sigma \) is contained in the (+)-cluster of \( x \) at \( \sigma^x \), and the flipping of \( \sigma_x \) to 1 shortens the boundary of \( C \); this may be taken as another case of the above with \( m + n = 1 \) and \( 0 \leq k \leq 3 \).) Here in place of (3.24) we have

\[ C_l(\sigma) = \{ \gamma_j : 1 \leq j \leq m, |\gamma_j| \geq 2\delta_1 l \}. \]  

(3.33)

Statement (3.25) still holds, and in place of (3.31) we will prove

\[ \Delta_{\gamma_1,\ldots,\gamma_m,\gamma_1',\ldots,\gamma_n'} H_{\Lambda(l)}^\omega(\sigma) \geq \varepsilon_{3.34} S_- - C_{3.34}, \]  

(3.34)

It is easy to see that for fixed \( x \), both for \( \sigma_x = 1 \) and for \( \sigma_x = -1 \), the sets \( \{ \gamma_1, \ldots, \gamma_m, \gamma_1', \ldots, \gamma_n' \} \) and \( \{ \gamma, \alpha_1, \ldots, \alpha_k \} \) uniquely determine each other.

We now turn to the proof of (3.31) for \( \sigma_x = 1 \) and (3.34) for \( \sigma_x = -1 \). For \( \sigma_x = 1 \) we have using (3.29) that

\[ \frac{1}{2} \Delta_{\gamma,\alpha_1,\ldots,\alpha_k} H_{\Lambda(l)}^\omega(\sigma) \geq \frac{1}{2} \Delta_{\gamma,\alpha_1,\ldots,\alpha_k} H_{\Lambda(l)}^\omega(\sigma) - 4 \geq \frac{1}{2} \Delta_{\gamma_1,\ldots,\gamma_m,\gamma_1',\ldots,\gamma_n'} H_{\Lambda(l)}^\omega(\sigma^x) - 8 \]

\[ = \frac{1}{2} \Delta_{\gamma_1,\ldots,\gamma_m} H_{\Lambda(l)}^\omega(\sigma^x) + \frac{1}{2} \Delta_{\gamma_1',\ldots,\gamma_n'} H_{\Lambda(l)}^\omega(T\sigma^x) - 8 \]  

(3.35)

where \( T = T_{\gamma_1} \circ \cdots \circ T_{\gamma_m} \) (Recall (3.4)). Each contour in \( \{ \gamma_j \} \) is non-crossing, since \( |\gamma_j| < 2\delta_1 l \). Therefore, we see from (3.3) that for any \( 0 \leq p \leq m \),

\[ \frac{1}{2} \Delta_{\gamma_1,\ldots,\gamma_m} H_{\Lambda(l)}^\omega(\sigma^x) \geq \frac{1}{2} \Delta_{\gamma_1,\ldots,\gamma_p} H_{\Lambda(l)}^\omega(\sigma^x) + \sum_{j=p+1}^m \left( \frac{1}{2} |\gamma_j| - |\gamma_j \cap \partial \Lambda(l)| \right) \]

\[ \geq \frac{1}{2} \Delta_{\gamma_1,\ldots,\gamma_p} H_{\Lambda(l)}^\omega(\sigma^x) \geq 0. \]  

(3.36)
On the other hand, we have
\[ \Delta_{\gamma_1',\ldots,\gamma_n'} H^\omega_{\Lambda(l)}(T^{\sigma^x}) = 2\sum_{j=1}^n |\gamma_j'|, \] (3.37)
since \( \gamma_j' \cap \partial \Lambda(l) = \emptyset \). We have as a consequence that
\[ \frac{1}{2} \Delta_{\gamma_1,\ldots,\gamma_k} H^\omega_{\Lambda(l)}(\sigma) \geq \frac{1}{2} \Delta_{\gamma_1,\ldots,\gamma_p} H^\omega_{\Lambda(l)}(\sigma^x) + \sum_{j=1}^n |\gamma_j'| - 8. \] (3.38)
Note also that the first term on the right-hand-side of (3.38) is non-negative by (3.36). For \( \sigma_x = -1 \), \( \gamma \) is non-crossing since \( |\gamma| < 2\delta l \), and each \( \alpha_j \) is inside \( \gamma \), so it follows from (3.28) that
\[ \partial Q(x) \cup (\cup_{j=1}^m \gamma_j) \text{ is non-crossing in } Q(\Lambda(l)); \] (3.39)
in particular each \( \gamma_j \) is non-crossing. Therefore (3.35)–(3.38) remain valid but with \( \sigma \) and \( \sigma^x \) interchanged; in fact we may replace (3.38) with
\[ \frac{1}{2} \Delta_{\gamma_1,\ldots,\gamma_m,\gamma_1',\ldots,\gamma_n'} H^\omega_{\Lambda(l)}(\sigma) \geq \frac{1}{2} \Delta_{\gamma_1,\ldots,\gamma_p} H^\omega_{\Lambda(l)}(\sigma^x) + \sum_{j=1}^n |\gamma_j'|. \] (3.40)

To bound (3.38) or (3.40) from below, we pick a number \( \delta_2 \) such that
\[ \delta_2 < \delta_1 \] and
\[ \sum_{j=1}^m |\gamma_j| \leq (\delta_2/\delta_1) S_+. \] Consider first \( \sigma_x = 1 \). Here by (3.30)
\[ \sum_{j=1}^n |\gamma_j| \geq S_+ - \sum_{j=1}^m |\gamma_j| \geq \left( 1 - \frac{\delta_2}{\delta_1} \right) S_+, \] (3.43)
which, together with (3.38), proves (3.31) in this case. Using again (3.30), the same argument with (3.40) replacing (3.38) proves (3.34) when \( \sigma_x = -1 \).

Case 2: \( \sum_{j=1}^m |\gamma_j| > (\delta_2/\delta_1) S_+ \) and \( S_+ < 9l \). By (3.30), (3.38) and (3.40) it is enough to prove that
\[ \Delta_{\gamma_1,\ldots,\gamma_p} H^\omega_{\Lambda(l)}(\sigma^x) \geq \varepsilon l - c \] (3.44)
for some $\varepsilon > 0$, $c \geq 0$ and $1 \leq p \leq m$. We consider several subcases as follows.

Case 3.1: $\sum_{j=1}^{m} |\gamma_j \cap \partial Q(\Lambda(l))| \leq 2^3 l$. Consider first $\sigma_x = 1$. Since

$$\delta_2 l \leq \frac{1}{2}(\delta_2/\delta_1)|\gamma| \leq \frac{1}{2}(\delta_2/\delta_1)S_+ \leq \frac{1}{2} \sum_{j=1}^{m} |\gamma_j|,$$

we have by (3.36) that

$$\frac{1}{2} \Delta_{\gamma_1, \ldots, \gamma_m} H_{\Lambda(l)}(\sigma^x) \geq (\delta_2 - \delta_{2,3}) l$$

which proves (3.44). For $\sigma_x = -1$, in place of (3.45) we use (3.32) to obtain

$$\delta_2 l \leq \delta_1 l \leq \frac{1}{2} \sum_{j=1}^{m} |\gamma_j|;$$

otherwise the argument for (3.44) is the same.

Case 3.2: The set $\partial Q(x) \cup (\bigcup_{j=1}^{m} \gamma_j)$ is non-crossing in $\Lambda(l)$ and

$$\sum_{j=1}^{m} |\gamma_j \cap \partial Q(\Lambda(l))| \geq \delta_{2,3} l.$$

In this case we have

$$\left(\bigcup_{j=1}^{m} \gamma_j\right) \cap \left(F_i^i \cup F_{i}^k\right) = \emptyset$$

for some $i, k$ with $|i| = 1$ and $|k| = 2$. Then there exists a connected subset, say $\lambda$, of

$$\left(\bigcup_{j=1}^{m} \gamma_j\right) \cup \partial Q(x)$$

which divides $\Lambda(l)$ into two connected components $\tilde{\Theta}$ and $\Lambda(l) \setminus \tilde{\Theta}$ such that $\bigcup_{j=1}^{m} \Theta(\gamma_j) \subset \tilde{\Theta}$ and $F_i^i \cup F_{i}^k \subset \partial_{ex} (\Lambda(l) \setminus \tilde{\Theta})$. Note that the set $I$ defined by $I = \partial_{ex} \Lambda(l) \cap \partial \tilde{\Theta}$ is an interval. To prove (3.44) by applying (3.15), let us check (3.13) and (3.14) with $p = m$. We see from the construction of $I$ that

$$\bigcup_{j=1}^{m} I(\gamma_j) \subset I,$$

$$|I| \leq |\lambda| \leq \sum_{j=1}^{m} |\gamma_j| + 4.$$

On the other hand, we see from (3.46) that

$$|I| \geq \sum_{j=1}^{m} |\gamma_j \cap \partial \Lambda(l)| \geq \delta_{2,3} l.$$

We therefore have (3.13) and (3.14) with $p = m$.

Case 3.3: The set $\partial Q(x) \cup (\bigcup_{j=1}^{m} \gamma_j)$ is crossing in $\Lambda(l)$. By (3.39) this is possible only when $\sigma_x = 1$. There exist $1 \leq i < j \leq 4$ and $k \in \{1, 2\}$ such that

$$\gamma_i \cap F_i^k \neq \emptyset \quad \text{and} \quad \gamma_j \cap F_{-k}^i \neq \emptyset.$$

(3.47)
Let us assume (3.47) with $i = 1$, $j = 2$, and $k = 1$. Then, the set $\gamma_1 \cup \gamma_2$ cannot be vertically crossing, since $|\gamma_1| + |\gamma_2| < 4\delta_1 l$ and $\gamma_1 \cup \gamma_2$ is already horizontally crossing. Let us therefore assume that

$$ (\gamma_1 \cup \gamma_2) \cap F_i^{-2} = \emptyset. \tag{3.48} $$

We are now left with two possibilities.

Case 3.3.1: $\gamma_1 \cap F_i^2 \neq \emptyset$ and $\gamma_2 \cap F_i^2 \neq \emptyset$. In this case, $I = I(\gamma_1) \cup I(\gamma_2) \cup F_i^2$ is an interval. To prove (3.44) by applying (3.15), we will check (3.13) and (3.14) with $p = 2$. We obviously have

$$ \bigcup_{j=1}^2 I(\gamma_j) \subset I, \quad |I| \geq l. $$

On the other hand, it is easy to see we have the following injections:

$$ I(\gamma_1) \cap F_i^1 \rightarrow \{\text{vertical dual bonds in } \gamma_1\}, $$

$$ I(\gamma_2) \cap F_i^{-1} \rightarrow \{\text{vertical bonds in } \gamma_2\}, $$

$$ F_i^2 \rightarrow \{\text{horizontal bonds in } (\gamma_1 \cup \gamma_2) \cup \partial Q(x)\}. $$

We get $|I| \leq |\gamma_1| + |\gamma_2| + 4$ as a consequence. We therefore have (3.13) and (3.14) with $p = 2$.

Case 3.3.2: $\gamma_1 \cap F_i^2 = \emptyset$ or $\gamma_2 \cap F_i^2 = \emptyset$. Let us assume $\gamma_1 \cap F_i^2 = \emptyset$, so that $\gamma_1$ does not intersect with $F_i^j$, $j \neq 1$. The distance from $x$ to $F_i^{-1}$ is at most $\delta_1 l$, and hence the distance from $x$ to $F_i^1$ is at least $(1 - \delta_1) l$. This implies that $\gamma_1$ deviates from $F_i^1$ at least by distance $(1 - \delta_1) l - 1$. Therefore, by (3.21),

$$ \frac{1}{2} \Delta_\gamma H_{\Lambda(l)}^x(\sigma) \geq \{|\text{horizontal bonds in } \gamma\}| \geq 2(1 - \delta_1) l - 2, $$

which establishes (3.44) with $p = 1$.

Step 2: Suppose again that $\sigma \in \Gamma_l$ and $\sigma^x \notin \Gamma_l$. If $\sigma_x = 1$, then every (+)-contour outside $\gamma$ at $\sigma$ has length at most $2\delta_1 l$, and every (+)- or (−)-contour inside $\gamma$ does not intersect $\partial Q(\Lambda(l))$. It follows that

$$ T_{\gamma} \circ T_{\alpha_1} \circ \cdots \circ T_{\alpha_k} \sigma \in \Gamma_l. \tag{3.49} $$

Similarly if $\sigma_x = -1$ then

$$ T_{\gamma_1} \circ \cdots \circ T_{\gamma_m} \circ T_{\gamma'_1} \circ \cdots \circ T_{\gamma'_n} \sigma \in \Gamma_l. \tag{3.50} $$

Step 3: For $x \in \Lambda(l)$ and $\sigma \in \Gamma_l$ with $\sigma^x \notin \Gamma_l$, let $C_+(\sigma, x)$ denote the set of contours $\{\gamma, \alpha_1, \cdots, \alpha_k\}$, defined previously, if $\sigma_x = 1$, and let $C_-(\sigma, x) = \{\gamma_1, \cdots, \gamma_m, \gamma'_1, \cdots, \gamma'_n\}$ if $\sigma_x = -1$. We have by observations made in Step 1 that

$$ \sum_{x \in \Lambda(l)} \sum_{\sigma \in \Gamma_l, \sigma^x \notin \Gamma_l, \sigma_x = 1} \mu^\beta_{\Lambda(l), \omega}(\sigma) \sum_{x \in \Lambda(l)} \sum_{\gamma, \alpha_1, \cdots, \alpha_k} \mu^\beta_{\Lambda(l), \omega} \{\sigma : C_+(\sigma, x) = \{\gamma, \alpha_1, \cdots, \alpha_k\}, \Delta_{\gamma, \alpha_1, \cdots, \alpha_k} H_{\Lambda(l)}^\omega(\sigma) \geq \varepsilon_{3.31} S_+ - C_{3.33}\} \geq \varepsilon_{3.31} S_+ - C_{3.33} \tag{3.51} $$
where $\sum_{\gamma, \alpha_1, \ldots, \alpha_k}$ stands for the summation over all possible values of $C_+ (\sigma, x)$. Now for fixed $x$ and $n$ there are at most $c \cdot 3^n$ possible values of $C_+ (\sigma, x)$ for which $S_+ = n$. By the standard Peierl’s argument and the observation made in Step 2, we can proceed as follows, provided $\beta$ is sufficiently large:

$$
\sum_{x \in \Lambda(l)} \sum_{\gamma, \alpha_1, \ldots, \alpha_k} \mu_{\Lambda(l)}^\beta \left\{ \sigma : C_+ (\sigma, x) = \{\gamma, \alpha_1, \ldots, \alpha_k\}, \Delta_{\gamma, \alpha_1, \ldots, \alpha_k} H_{\Lambda(l)}^\omega (\sigma) \geq \varepsilon 3.31 S_+ - C_3 \right\} \\
\leq \sum_{x \in \Lambda(l)} \sum_{\gamma, \alpha_1, \ldots, \alpha_k} \exp (-\beta (\varepsilon 3.31 S_+ - C_3)) \\
\cdot \mu_{\Lambda(l)}^\beta \left\{ T_\gamma \circ T_{\alpha_1} \circ \cdots \circ T_{\alpha_k} \sigma : C_+ (\sigma, x) = \{\gamma, \alpha_1, \ldots, \alpha_k\} \right\} \\
\leq \sum_{x \in \Lambda(l)} \sum_{n \geq 2^{3l}} c \cdot 3^n \exp (-\beta (\varepsilon 3.31 n - C_3)) \mu_{\Lambda(l)}^\beta (\Gamma^c_i) \\
\leq B_3 \exp (-\beta l / C_3 \beta) \mu_{\Lambda(l)}^\beta (\Gamma^c_i). \tag{3.52}
$$

Essentially the same argument, using $C_- (\sigma, x)$ and $S_-$ in place of $C_+ (\sigma, x)$ and $S_+$, shows that

$$
\sum_{x \in \Lambda(l)} \sum_{\sigma \in \Gamma_1 : \sigma \not\in \Gamma_1, \sigma_x = -1} \mu_{\Lambda(l)}^\beta (\sigma) \leq B_3 \exp (-\beta l / C_3 \beta) \mu_{\Lambda(l)}^\beta (\Gamma^c_i). \tag{3.53}
$$

We conclude (2.10) from (3.51), (3.52) and (3.53). \qed
