Unique invariant natural killer T cells promote intestinal polyps by suppressing TH1 immunity and promoting regulatory T cells

Y Wang1, S Sedimbi1,3, L Löfbom1, AK Singh1, SA Porcelli2 and SL Cardell1

CD1d-restricted invariant natural killer T (iNKT) cells are known as potent early regulatory cells of immune responses. Besides the established roles in the regulation of inflammation and autoimmune disease, studies have shown that iNKT cells have important roles in tumor surveillance and the control of tumor metastasis. Here we found that the absence of iNKT cells markedly decreased the total number of intestinal polyps in APCMin/þ mice, a model for colorectal cancer. Polyp iNKT cells were enriched for interleukin-10 (IL-10)- and IL-17-producing cells, showed a distinct phenotype being CD4þ, NK1.1−CD44int, and PD-1lo, and they were negative for the NKT cell transcription factor promyelocytic leukemia zinc-finger. The absence of iNKT cells was associated with a reduced frequency of regulatory T (Tregs) cells and lower expression levels of FoxP3 protein and transcript uniquely in the polyps, and a switch to an inflammatory macrophage phenotype. Moreover, in iNKT cell-deficient APCMin/þ mice, expression of T-helper (TH) 1-associated genes, such as IFN-γ and Nos2, was increased in polyps, concomitantly with elevated frequencies of conventional CD4+ and CD8+ T cells in this tissue. The results suggest that a population of regulatory iNKT cells locally promote intestinal polyp formation by enhancing Treg cells and immunosuppression of antitumor TH1 immunity.

INTRODUCTION

Lipid-reactive CD1d-restricted natural killer T (NKT) cells are potent early regulatory cells of diverse immune responses. Besides the established roles in the regulation of immunity to infection, and in inflammation and autoimmune disease, many studies have attributed NKT cells an important role in tumor surveillance and the control of tumor metastasis.1 NKT cells can be divided into two functionally distinct categories according to their expression of T-cell receptors (TCRs).2,3 An evolutionarily conserved category of NKT cells (termed invariant, iNKT cells, or type 1 NKT cells) expresses a semi-invariant TCR containing a specific TCRα chain (in humans Vα24-JαQ, in mice Vα14-Jα18).4 CD1d presents glycolipids to NKT cells, and essentially all iNKT cells are activated by the artificial lipid ligand α-galactosylceramide (αGalCer), first described for its strong antitumor effect.5 The remaining CD1d-reactive TCRβ cells have diverse TCR (termed diverse, dNKT cells, or type 2 NKT cells).2 Studies using αGalCer treatment have established that iNKT cells have antitumor functions in several murine experimental models. Moreover, in some models iNKT cells demonstrate “natural” tumor surveillance, i.e., in the absence of activation with administered iNKT cell ligands.6–8 Interferon-γ (IFN-γ) production by iNKT cells has been identified as an essential component of their antitumor activity. Further, several reports found that cancer patients have reduced levels of NKT cells that show a functional deficiency in IFN-γ production, and that higher levels of NKT cells correlated with improved prognosis.9 On the other hand, dNKT cells have been found to suppress CD8+ T-cell-mediated tumor immunity in an interleukin-13 (IL-13) and tumor growth factor-β-dependent manner.9 Findings in peripheral blood from myeloma patients seem to support this dichotomy. An expanded population of dNKT cells was demonstrated, and interestingly, these cells produced IL-13 and were reactive to an inflammation-associated lyso-phospholipid presented on CD1d.10 Thus, different roles have
often been associated with the two NKT subsets, and a model
has been put forward proposing that iNKT cells promote tumor
immunity, whereas dNKT cells suppress tumor immunity.9

Human inflammatory bowel disease increases the risk of
developing colorectal cancer; consistent with a role for chronic
inflammation in promoting carcinogenesis.11 In this context, it
is significant that NKT cells were demonstrated to promote
intestinal inflammation in Crohn’s disease and mouse models.12–14
The demonstrated role of NKT cells in chronic
intestinal inflammation raises the question of whether these
enhance inflammation-driven intestinal tumor formation by
their capacity to promote inflammation, or prevent tumor
formation at this site through their ability to provide tumor
surveillance and tumor prevention. ApcMin/+ mice are a model
for human colorectal cancer (CRC),15 which is the leading
cause of cancer-related mortality worldwide. The ApcMin/+ mice have a truncated adenomatous polyposis coli (Apc) gene, a
mutation that leads to the spontaneous formation of benign
intestinal adenomatous polyps in heterozygote mice, recapit-
ulating early events in human colorectal carcinogenesis.
Several studies have demonstrated the critical role of inflam-
mation driving the formation of polyps in human CRC and
mouse models of the disease,16 and blocking of both innate
immunity, whereas dNKT cells suppress tumor immunity.9

RESULTS
iNKT cells naturally promoted intestinal tumor
development

We first determined whether the heterozygous Apc mutation in
ApcMin/+ mice affected the numbers and the functions of iNKT
cells. In our animal facility, 10–12-week-old ApcMin/+ mice had
no macroscopically visible intestinal polyps, but early polyp
formation could be seen on sections using a microscope
(Figure 1a). iNKT cell frequencies were similar in the spleen,
mesenteric lymph nodes (MLNs) (Figure 1b) and liver (data
not shown) of ApcMin/+ and Apc+/+ mice at this age. Further,
ApcMin/+ and Apc+/+ mice responded to CD1d-restricted NKT cells
with vigorous production of cytokines at comparable levels
detected in the serum at 2 to 24 h (Figure 1c). Thus, iNKT
cells in 10–12-week-old ApcMin/+ mice were present in equal
frequencies and demonstrated a normal in vivo responsiveness
to CD1d-stimulated iNKT cells when compared with their Apc+/+ littermate control mice.

At 15 weeks of age, intestinal polyps were visible in all
ApcMin/+ mice with a median of ~20 polyps over the entire
length of the intestine, with no significant difference between
male and female ApcMin/+ mice (data not shown). To investi-
gate the influence of iNKT cells on the natural course of polyp
development in ApcMin/+ mice, we crossed the mice with
Jx18−/− mice that specifically lack iNKT cells. The spleno-
megaly19 was reduced in ApcMin+/+ Jx18−/− mice compared with
the ApcMin+/+ Jx18−/− controls (Figure 1d), and
ApcMin+/+ Jx18−/− had an ~75% reduction in the median
number of polyps in the small intestine (SI) compared with
the heterozygote (ApcMin+/ Jx18+/−) littermate controls
(Figure 1e). We also crossed ApcMin/+ mice with CD1d-
deficient mice lacking all NKT cells. Compared with ApcMin+/+ CD1d+/− littermate controls, ApcMin+/+ CD1d+/− mice
demonstrated a 56% decrease in SI polyp counts (Figure 1f).
Neither of the two NKT-deficient mice harboring the
ApcMin+/+ mutation had significantly reduced numbers of
polyps in the colon. Thus, two different mutations resulting in
inNKT cell deficiency had reduced polyp numbers,
demonstrating that iNKT cells naturally promote tumor
development in this model. Moreover, the similar reduction in
polyp numbers in mice lacking iNKT cells and all NKT cells
suggests that dNKT cells do not have significant effects on
tumor development in this model.

We next investigated the effect of activation of iNKT cells
during polyp development. Mice were treated from 5 to 15
weeks of age with αGalCer that induces a mixed T-helper
(TH1)/TH2 cytokine profile, or with the modified ligand
C20:2 that induces preferential TH2 cytokine production by
iNKT cells.20 αGalCer treatment reduced polyp numbers in
both SI and colon, whereas SI polyp numbers in mice treated
with C20:2 were significantly higher (Figure 1g). This demon-
strated that ligand-activated iNKT cells have the capacity to
control polyp development in both SI and colon, and indicated
that activation of TH1 cytokine secretion by iNKT cells
led to suppressed polyp development, whereas induction of
iNKT cell-derived TH2 cytokines rather enhanced polyp
development.

Unique phenotype and functions of iNKT cells in polyps of
ApcMin/+ mice

To address the underlying mechanisms for the promotion of
polyps in ApcMin/+ mice by iNKT cells, we first performed a
broad analysis of iNKT cells in polyps and different lymphoid
organs. Polyp-infiltrating lymphocytes contained ~0.6%
iNKT cells, which is similar to iNKT cell percentages in
lamina propria (LP) lymphocytes from ApcMin/+ and Apc+/+
mice (Figure 2b). In MLN and spleen the frequencies of
iNKT cells were comparable in both mice (Figure 2b).
Owing to the splenomegaly of ApcMin/+ mice, the absolute number of
splenic iNKT cells was slightly but significantly increased, while
in contrast, the total numbers of CD4 and CD8 T and B cells
remained the same (data not shown). In vitro stimulation of
splenocytes induced similar frequencies in both mice of
IL-4- and IFN-γ-producing iNKT cells (data not shown).

In an extended phenotypic analysis, we did not detect
differences between iNKT cells when comparing the same
tissues from ApcMin/+ and Apc+/+ mice, but we confirmed
previous publications showing that iNKT cells at different
locations have distinct phenotypes21 (Figure 2c). In polyps of
ApcMin/+ mice, the fraction of iNKT cells expressing CD4 and
NK1.1 was lower than in other organs. In contrast, CD69 (not
shown) and CD44 was expressed by almost all polyp iNKT cells,
but CD44 levels were strongly decreased compared with splenic
iNKT cells, and only ~10% of iNKT cells in polyps displayed
frequencies of NK1.1

The iNKT population in MLN of both mice had similarly low

however, the majority of LP iNKT cells expressed PD-1.

proportions of cells displaying NK1.1 and high CD69;

Expression of the transcription factor promyelocytic leukemia zinc-finger (PLZF) is a known feature of both developing and mature iNKT cells. In addition, iNKT cells can be divided into distinct functional subsets that express characteristic sets of transcription factors determining the pattern of cytokines secreted upon activation, analogous to T-helper 1 (TH1), TH2, and TH17 cells. Three major functional subsets have been defined, iNKT1, iNKT2, and iNKT17, that are distributed in different ratios in various lymphoid organs. We stained polyp

the marker of activation/exhaustion, PD-1 (CD279) (Figure 2c). Similarly, LP iNKT cells demonstrated low proportions of cells displaying NK1.1 and high CD69; however, the majority of LP iNKT cells expressed PD-1. The iNKT population in MLN of both mice had similarly low frequencies of NK1.1+, CD69+, and PD-1+ cells (∼20%). Therefore, polyp iNKT cells displayed a cell surface phenotype that was different from iNKT cells in the other organs analyzed.
iNKT cells for intracellular transcription factors and compared them with iNKT cells in LP, MLN, and spleen (Figure 2d–f). Surprisingly, polyp iNKT cells were essentially negative for PLZF, with a similar median fluorescence intensity (MFI) level to splenic CD4+ T cells. These PLZF-negative iNKT cells fall outside the established gating for iNKT1/2/17 cell subsets (see gating in Figure 2d). Here, we have termed the PLZF-negative iNKT cells “iNKT-Pneg”. Strikingly, over 90% of iNKT cells in polyps were iNKT-Pneg, iNKT cells in LP of both mice expressed PLZF, but at lower levels than iNKT cells from the spleen and MLN. Among iNKT cells in control Apc+/-+LP, ~30% were iNKT-Pneg by our definition, and ~55% were iNKT1, whereas LP of ApcMin/+ mice had slightly but significantly lower frequency of iNKT1 cells and a somewhat increased frequency of iNKT-Pneg cells. Splenic iNKT cells consisted almost exclusively of iNKT1 cells, whereas MLN iNKT cells displayed equal frequencies of iNKT1 and iNKT2 cells and a distinct iNKT17 population of ~10%, and there was no difference between iNKT cells from ApcMin/+ and Apc+/-/+ mice in these organs. Around 10% of all iNKT cells in MLN, LP, and polyp expressed RAR-related orphan receptor γt (ROγt) (Figure 2f), whereas the levels of ROγt were somewhat lower in polyp iNKT cells compared with other organs. Some of the ROγt+ iNKT cells in LP, and the majority in polyps, were PLZF negative (thereby falling within the iNKT-Pneg definition in Figure 2d). Thus, polyp iNKT cells displayed a transcription factor pattern that was different from the established iNKT functional subsets, most notably by lacking the NKT cell transcription factor PLZF. This suggests that polyp iNKT cells possess a distinct functional capacity that underpins tumor promotion occurring at this site.

Considering that iNKT cells in polyps did not express the expected transcription factors that determine iNKT cell functional status, we determined intracellular cytokines in iNKT cells activated in vivo with αGalCer (Figure 2g and h). As shown before,24 we found that MLN iNKT cells responded poorly to systemic αGalCer stimulation (data not shown). Unstimulated iNKT cells in polyps contained detectable frequencies of cells positive for IL-2, IL-4, IL-13, tumor necrosis factor-α, and IL-17 but not IFN-γ, something that was also seen in LP, but was absent in splenic iNKT cells. After in vivo stimulation, iNKT cells in polyps harbored significant frequencies of cells positive for IFN-γ (~20%), IL-2, IL-4, IL-13, and tumor necrosis factor-α (all ~10%); however, the frequencies were lower than found in splenic iNKT cells. Strikingly, however, polyp iNKT cells were strongly enriched for cells containing IL-10 or IL-17 compared with both spleen and LP iNKT cells, particularly evident at 4h (Figure 2h). Taken together, this demonstrates that αGalCer-activated polyp iNKT cells secreted a different pattern of cytokines compared with spleen and LP iNKT cells, notably being enriched for IL-10- and IL-17-producing cells.

iNKT cells controlled accumulation, activation, and functional status of polyp-infiltrating T cells

We next defined differences in T cells infiltrating the polyp in iNKT cell-deficient ApcMin/+ Jx18-/- and ApcMin/+ Jx18+/- mice. Lack of iNKT cells resulted in elevated frequencies of CD8+ T cells in polyps as well as of conventional CD4+ T cells (CD4+ FoxP3-, convCD4 cells) in both polyps and MLN of ApcMin/+ Jx18-/- mice (Figure 3a). Further, in the absence of iNKT cells the expression of PD-1 was reduced on CD8 T cells in both polyps and LP and on convCD4 T cells in LP, consistent with a lower degree of exhaustion (Figure 3b and c). In polyps, where PD-1 expression on convCD4 cells was very low, the frequency of PD-1+ cells was slightly increased. Moreover, in polyp, LP, and MLN there was a significant reduction in the expression of the IL-33 receptor ST2, associated with TH2 cells, by convCD4 cells (Figure 3c), suggesting that iNKT cells provide an environment that is more supportive of this TH subset. Both CD8 and convCD4 T populations displayed strongly reduced frequencies of CD69+ cells in polyps of ApcMin/+ Jx18-/- mice compared with ApcMin/+ Jx18+/- mice. CD69 is known as a marker of early activation of T cells in lymphoid organs and tissue-resident memory T cells; however, studies also suggest that CD69 negatively regulates proinflammatory functions of T cells in tissues (see Gonzalez-Amaro et al.25 for review). In the absence of iNKT cells, a lower frequency of convCD4 and CD8 T cells within polyp tissue was engaged in proliferation, as indicated by reduced Ki67 expression. Taken together, this demonstrates that, directly or indirectly, iNKT cells control accumulation and activation-functional status of convCD4 and CD8 T cells in the polyp tissue.
iNKT cells promoted a regulatory, and suppressed a Th1/proinflammatory polyp microenvironment

To determine the immune- and tumor-related molecular signatures that distinguish the iNKT cell-mediated promotion of tumor burden in ApcMin/+ mice, a quantitative PCR array screen was performed for the expression of a set of genes relevant for immune responses, tumor growth, and apoptosis (Figure 4a and b). We considered that iNKT cells may promote tumor development by proinflammatory actions increasing the production of tumor growth factors, and also the possibility that tumor enhancement was due to increased immunoregulation, resulting in decreased tumor immunity. Gene expression in polyp and LP from ApcMin/+Ja18+/– and ApcMin/+Ja18–/– mice were compared, resulting in the identification of several genes that were altered in expression in the absence of iNKT cells (Figure 4a and b). Lack of iNKT cells resulted in upregulated expression in polyps of genes associated with a Th1/proinflammatory immune response, such as those encoding IFN-γ, iNOS (Nos2), IL12p40, T-bet (Tbx21), granzyme B (Gzmb), and Stat-1. In contrast, transcript levels of Foxp3, the master transcription factor for regulatory T (Treg) cells, in polyps were decreased. Interestingly, iNKT cell deficiency resulted in enhanced Th1/inflammation-associated gene expression also in LP (increased expression of genes encoding iNOS, IFN-γ, CD8β, CXCL9, CXCL10, granzyme B). We performed quantitative PCR on tissue samples from individual mice for a set of genes to verify the array results (Figure 4c). The results confirmed significantly higher expression levels of Ifng and Nos2 in both polyp and LP in the absence of iNKT cells. In iNKT-sufficient control mice, the levels of both Il17a and Foxp3 transcripts were higher in polyp tissue compared with LP. Notably, the absence of iNKT cells was associated with a decrease in Foxp3 expression in the polyps but not LP. This strongly indicates that iNKT cells promoted polyp development by enhancing immune regulation and suppressing Th1-associated tumor immunity.

Figure 3  Increased frequency of conventional T cells in polyps in the absence of invariant natural killer T (iNKT) cells. (a) Frequency of conventional CD4+ (CD4+Foxp3–) T cells and CD8+ T cells among lymphocytes in ApcMin/+Ja18–/– mice and their ApcMin/+Ja18–/– littermate controls. (b) Representative staining and summary data of CD69, Ki67, and PD-1 expression on CD8+ T cells in ApcMin/+Ja18–/– and ApcMin/+Ja18–/– mice. (c) Representative staining and summary data of ST2, CD69, Ki67, and PD-1 expression on conventional CD4+ T cells in ApcMin/+Ja18–/– and ApcMin/+Ja18–/– mice. Data from at least three independent experiments are presented as mean ± s.d. of seven to ten mice (CD69) and three to six mice (Ki67, PD-1, and ST2) per genotype. Mann–Whitney test was used for statistical analyses. *P<0.05, **P<0.01, and ***P<0.001.
iNKT cells supported the expression of FoxP3 and an activated Treg cell phenotype in polyps

The decreased FoxP3 expression in polyps from Apc<sup>Min−/+</sup> Jα18<sup>−/−</sup> mice compared with Apc<sup>Min−/+</sup> Jα18<sup>+/−</sup> mice prompted a comprehensive analysis of Treg cells by flow cytometry (Figure 5). In iNKT cell-deficient polyps, but not LP or other lymphoid organs, the frequency of Treg cells (both when gated as CD25<sup>+</sup> FoxP3<sup>+</sup> cells or as FoxP3<sup>+</sup> cells) among CD4<sup>+</sup> cells was significantly decreased (Figure 5a and b). Notably, also the MFI level of FoxP3 in CD25<sup>+</sup> CD4<sup>+</sup> T cells was reduced in Apc<sup>Min−/+</sup> Jα18<sup>−/−</sup> mice. The same was true when FoxP3 levels were compared within the CD25<sup>+</sup> FoxP3<sup>+</sup> gate, suggesting that iNKT cells promote Treg in a manner that maintains higher levels of FoxP3 protein. Further, iNKT cells reinforced expression of the IL-33 receptor ST2 on both polyp and LP Treg cells. Extended phenotypic analysis revealed that the presence of iNKT cells was associated with an increased fraction of polyp Treg cells expressing CD25<sup>+</sup> CD4<sup>+</sup> cells or as FoxP3<sup>+</sup> cells or as FoxP3<sup>+</sup> cells (not shown). Taken together, this demonstrates that iNKT cells drive Treg cell maintenance and/or activation both in polyps and LP of Apc<sup>Min−/+</sup> mice.

Absence of iNKT cells led to a systemic shift in macrophage phenotype from M2 to M1

As we found that Nos2, expressed by macrophage subtype 1 (M1) cells, was the most strongly upregulated gene in Apc<sup>Min−/+</sup> Jα18<sup>−/−</sup> polyp and LP compared with Apc<sup>Min−/+</sup> Jα18<sup>+/−</sup> tissues, we investigated innate immune cells in polyps, LP, and spleen (Figure 6). MLN contained very low frequencies of these cells (data not shown). In the presence of iNKT cells there was an elevated frequency of CD11c<sup>+</sup> dendritic cells in the polyps compared with iNKT cell-deficient mice (Figure 6a and b). There was also a several-fold higher proportion of cells with a phenotype of myeloid-derived suppressor cells (MDSCs) commonly found in tumors<sup>26</sup>. Further, there was a significant increase in the frequency of F4/80<sup>+</sup> macrophages in the spleen (Figure 6a and b), consistent with the splenomegaly in Apc<sup>Min−/+</sup> Jα18<sup>−/−</sup> mice (Figure 1d). We next determined the macrophage expression of iNOS and CD206, characteristic of M1 and M2 macrophages, respectively. Strikingly, iNKT cell deficiency resulted in a highly significant shift in the macrophage phenotype in all tissues, from a mixed/M2-dominated population (high frequency of CD206<sup>+</sup>/low frequency of iNOS<sup>+</sup> cells) in Apc<sup>Min−/+</sup> Jα18<sup>−/−</sup> mice to a macrophage population strongly skewed toward the M1 phenotype in Apc<sup>Min−/+</sup> Jα18<sup>−/−</sup> mice.
Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} mice (high frequency of iNOS\textsuperscript{+} and strongly diminished proportion of CD206\textsuperscript{+} macrophages) (Figure 6c and d). In the spleen, the proportion of macrophages expressing CD11c, also described as an M1 macrophage marker, was increased in the absence of iNKT cells, whereas, surprisingly, in polyps of the same mice the frequency of macrophages expressing CD11c was reduced (Figure 6d).

Interestingly, in polyps and other tissues analyzed we found that CD11c and iNOS were expressed by distinct subsets of F4/80\textsuperscript{+} cells (data not shown), indicating heterogeneity of macrophages beyond a simple M1/M2 division. Further analysis of the MDSC population revealed that the majority of MDSC in iNKT-sufficient Apc\textsuperscript{Min/+} mice were polymorphonuclear-MDSC (PMN-MDSC; Ly6C\textsuperscript{int}/Ly6G\textsuperscript{−}).

Figure 5 Invariant natural killer T (iNKT) cells supported the expression of FoxP3 and an activated polyp regulatory T (Treg) cell phenotype. (a) Representative stainings show a decreased level of FoxP3 protein in Treg cells from Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} and Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} mice. (b) Frequencies of CD25\textsuperscript{+}FoxP3\textsuperscript{+} T cells (left) and total FoxP3\textsuperscript{+} T cells (right) among CD4\textsuperscript{+} T cells in Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} and Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} mice. (c) Median fluorescence intensity (MFI) of FoxP3 staining in CD25\textsuperscript{+} cells (left) or in FoxP3\textsuperscript{+} cells (right) in different tissue in the presence and absence of iNKT cells. (d) Representative staining of CD69 and ST2 on Treg cells in polyps from Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} mice and Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} mice. (e) Surface expression of CD69, PD-1, KLRG1, and ST2 on Treg cells in polyps from Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} mice and their Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} littermates. Data are presented as mean ± s.d. of seven mice from (a) and three independent experiments and (e) three mice from a representative experiment of three performed, and (b) three mice from two independent experiments. Mann–Whitney test was used for statistical analyses. *P<0.05, **P<0.01, and ***P<0.001.

Figure 6 Lack of invariant natural killer T (iNKT) cells resulted in a skewed macrophage phenotype from M2 to M1. Innate immune cells were investigated by flow cytometry in polyps, lamina propria (LP), and spleen of Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} and Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} mice. (a) Gating strategies for dendritic cells (DCs, CD3\textsuperscript{−}CD19\textsuperscript{−}CD45\textsuperscript{+}CD11ch\textsuperscript{−}), myeloid-derived suppressor cells (MDSCs) (CD3\textsuperscript{−}CD19\textsuperscript{−}CD45\textsuperscript{+}CD11c\textsuperscript{int}CD11b\textsuperscript{+}), and macrophages (Mac, CD3\textsuperscript{−}CD19\textsuperscript{−}CD45\textsuperscript{+}CD11c\textsuperscript{int}F4/80\textsuperscript{+}) are shown for Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} polyt, LP, and spleen. (b) Frequency of DCs, MDSCs, and Mac among CD45\textsuperscript{+} cells in indicated tissues. (c) Representative staining of iNOS and CD206 expression on macrophages. (d) Frequency of macrophages expressing iNOS, CD206, and CD11c in the same tissues. Data from three independent experiments are presented as mean ± s.d. of six mice. (e) Gating strategy for mononuclear MDSC (M-MDSC) (CD3\textsuperscript{−}CD19\textsuperscript{−}CD45\textsuperscript{+}CD11c\textsuperscript{int}CD11b\textsuperscript{−}Ly6C\textsuperscript{−}Ly6G\textsuperscript{−}) and polymorphonuclear-MDSC (PMN-MDSC) (CD3\textsuperscript{−}CD19\textsuperscript{−}CD45\textsuperscript{+}CD11c\textsuperscript{int}CD11b\textsuperscript{−}Ly6C\textsuperscript{+}Ly6G\textsuperscript{−}). (f) Frequency of M-MDSC and PMN-MDSC in Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} and Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} mice. (g) Apc\textsuperscript{Min/+}ja18\textsuperscript{−−} mice were adoptively transferred with 5 × 10\textsuperscript{5} hepatic iNKT cells or CD1d tetramer-negative \(\gamma\)\(\delta\) T cells (\(\gamma\)\(\delta\)T) twice, at 13 and 14.5 weeks of age and killed at 16 weeks of age. Nontransferred mice were also used as control. Representative stainings of iNOS and CD206 expression on macrophages are shown for each group. (h) Frequency of macrophages expressing iNOS and CD206 in the same tissues. Data are presented as mean ± s.d. of four mice. Mann–Whitney test was used for statistical analyses. *P<0.05, **P<0.01, and ***P<0.001.
This population was strongly reduced in Apc\(^{Min/+}\) Jx18\(^{−/−}\) mice lacking iNKT cells and similar in frequencies to mononuclear MDSC (Ly6C\(^{hi}/Ly6G^{−}\)) in these mice (Figure 6g and f). Thus, in the absence of iNKT cells, there was a strong shift from CD206\(^{+}\) M2 toward iNOS\(^{+}\) M1 macrophages in all tissues analyzed, and a reduction of PMN-MDSC most significantly in polyps.

To reinforce the notion that iNKT cells regulate the inflammatory microenvironment in polyps, we transferred sorted iNKT cells to Apc\(^{Min/+}\) Jx18\(^{−/−}\) mice and 3 weeks later investigated the effects of the transfer on macrophage phenotypes. Transfer of iNKT cells resulted in a striking reduction of iNOS expression and increase in CD206 expression among macrophages in the polyps (Figure 6g and h). In contrast, there was no significant change in macrophage expression of these markers in LP or spleen after iNKT cell transfer. Transfer of iNKT cell-depleted T cells did not change the macrophage phenotype in any of the organs compared with nontransferred mice. This is consistent with a model in which iNKT cells promote an anti-inflammatory environment specifically in the polyps, resulting in the enhancement of M2 macrophages.

**DISCUSSION**

iNKT cells are well known for their potent tumor immunosurveillance and the suppression of tumors after αGalCer therapy. In such models, activated iNKT cells combat tumors by the production of IFN-γ and downstream activation of cells including NK cells, dendritic cells and cytotoxic CD8 T cells, and by being directly cytotoxic against CD1d-expressing tumor cells (see for a review Terabe and Berzofsky\(^{27}\)). In contrast, in the present study, using two different mutant mouse strains that lack iNKT cells, we demonstrate that iNKT cells promoted the development of spontaneous intestinal polyps in Apc\(^{Min/+}\) mice, a model for early stages of human colorectal cancer. Surprisingly, we found that iNKT cell promotion of polyps was associated with an immunoregulatory polyp microenvironment, characterized by increased Treg and PMN-MDSC populations and an enhanced M2 macrophage phenotype, but suppressed TH1 immunity and reduced frequencies of tumor-infiltrating conventional CD4 and CD8 T cells. The results are summarized in the simplified model in Figure 7.

The absence of iNKT cells in Apc\(^{Min/+}\) mice was associated with increased expression of IFN-γ and iNOS, and a systemic switch in macrophage phenotype from M2 to M1. These changes are likely to be pivotal for the reduced tumor burden in Apc\(^{Min/+}\) Jx18\(^{−/−}\) mice. First, Apc\(^{Min/+}\) mice lacking iNOS have significantly more adenomas than iNOS-positive littermate controls.\(^{28}\) This is in line with human studies showing that high infiltration of cells positive for iNOS correlated with significantly improved prognosis in CRC.\(^{29}\) Moreover, M2- or M2-like tumor-associated macrophages are known to support tumor progression and suppress tumor immunity, whereas M1 macrophages are involved in antitumor immunity.\(^{30}\) Second, IFN-γ is shown to be tumor suppressive in Apc\(^{Min/+}\) mice.\(^{31}\) The source of IFN-γ was not investigated in our studies, but CD8\(^{+}\) T cells are likely candidates. Consistently, we found that the frequency of infiltrating CD8 T cells, as well as CD4 T cells, was increased in the absence of iNKT cells. This may be an indirect effect and result from the reduction of Treg frequency and activation status in Apc\(^{Min/+}\) Jx18\(^{−/−}\) mice, as it has been shown that depletion of Treg in Apc\(^{Min/+}\) mice results in the influx of T cells into the polyps.\(^{32}\) Also, in some other murine tumor models, iNKT cells have been shown to promote tumor growth, associated with suppressed CD8 T cells, decreased IFN-γ, and elevated IL-13 production.\(^{33,34}\) The underlying mechanism of suppression of tumor immunity by iNKT cells in these models may be similar to what has been described for D/NKT cells in a series of studies by Terabe et al.\(^{35,36}\) Here, IL-13 production by DNKT cells induced TGF-β production by CD11b\(^{+}\) Gr-1\(^{+}\) myeloid cells, which in turn inhibited the activation of tumor-specific CD8\(^{+}\) effector cells resulting in enhanced tumor growth. Such myeloid cells may be involved in the suppression of immunity in Apc\(^{Min/+}\) polyps as we found that the presence of iNKT cells also increased the polyp frequency of cells with a phenotype of MDSC that express Ly6G, a marker of PMN-MDSC that are strongly associated with tumor-promoting activity.\(^{26}\) Tumor infiltration by CD8 T cells has been associated with improved prognosis in many cancers including CRC,\(^{37}\) and more recently, extended studies of infiltrating immune cells in human CRC have established their important prognostic value, more broadly demonstrating that TH1 immunity and CD8 T cells in tumor infiltrates correlate with increased disease-free survival of patients.\(^{38}\) Thus, the suppression of TH1 immunity in Apc\(^{Min/+}\) polyps by the presence of iNKT cells is likely to be a major cause for the increased polyp numbers. In contrast, expression of IL-17A is associated with tumor promotion in human CRC and Apc\(^{Min/+}\) mice.\(^{39,40}\) We found that IL-17A transcript levels were highly variable in polyps in the presence of iNKT cells, but
not significantly altered in polyps in iNKT cell-deficient ApcMin/+ mice.

iNKT cell regulation of the immune environment in the polyps may partly be due to the promotion by iNKT cells of infiltrating Treg cells that had a phenotype associated with a higher activation state and elevated effector function. We show that in the presence of iNKT cells, the amount of FoxP3 mRNA in polyps was increased, and the frequency of positive cells and the fluorescence intensity of FoxP3 staining in Treg cells were augmented. Such differences were not detected in other tissues. Moreover, in the presence of iNKT cells, Treg cells in polyps showed a marked upregulation of ST2. ST2 was recently demonstrated to be expressed on high proportions of Treg cells in the colon as well as in the adipose tissue.40-42 IL-33 promoted their immunoregulatory function and maintenance of the Treg phenotype, including maintenance of FoxP3 expression, and increased expression of its own receptor ST2 on Treg. Importantly, ST2 deficiency protects from tumor development in an induced mouse model of CRC.43 Taken together, this suggests that iNKT cells promote the accumulation, activation and/or homeostasis of highly active immunoregulatory Treg cells in the polyp tissue. It is interesting to note that the induction of Treg cells by iNKT cells has also been shown to have a role for tolerance in autoimmune setting.s27

Although other tissues were also influenced, the most striking differences resulting from the absence of iNKT cells in ApcMin/+ mice were revealed in the polyps, especially with regard to Treg frequency and phenotype, suggesting that iNKT cells regulate immune cells in this tissue. This was also suggested by the polyp-specific effect on MDSC by depletion of iNKT cells in ApcMin/+ mice, and by the promotion of an M2 macrophage phenotype specifically in the polyps after transfer of iNKT cells to ApcMin/+ Jx18−/− mice. We found that iNKT cells infiltrated the ApcMin/+ polyps, but they were present in a relatively low frequency at this site. Polyp iNKT cells were predominantly NK1.1+, CD44int, PD-1−, and around half of them were negative for CD4, which differed from iNKT cells in LP and lymphoid organs, and strikingly, they were negative for PLZF. Moreover, while polyp iNKT cells had a generally lower cytokine production in vivo in response to zGC, they demonstrated a highly increased capacity to make IL-10 and IL-17. These polyp iNKT cells share some functional features and cell surface phenotype with the so-called iNKT10 cells that arise after strong zGC stimulation in vivo,44 and with iNKT cells that are present in white adipose tissue.44,45 Both adipose tissue iNKT and iNKT10 cells produced IL-10 upon activation, but had a decreased production of other tested cytokines compared with splenic iNKT cells in naive mice, and were ascribed regulatory functions. Similar to iNKT cells in ApcMin/+ mice, the induced iNKT10 cells suppressed tumor immunity and this effect was dependent on IL-10.44 Adipose tissue iNKT cells were shown to favor a noninflammatory adipose environment by promoting the homeostasis and regulatory function of adipose tissue Treg through the production of IL-2, and moreover, IL-10 dependently induced an anti-inflammatory state in local macrophages.45 Here, we demonstrate that polyp iNKT cells had very similar effects on polyp Treg cells and macrophages, despite the sevenfold lower frequency of iNKT cells in polyps (~0.6%) compared with adipose tissue (~4%; Lynch et al.45). The production of IL-10 and IL-2 by polyp iNKT cells may contribute to these effects. It was proposed that the adipose tissue regulatory iNKT phenotype was induced by chronic local stimulation. This may be true also for polyp iNKT cells, and is consistent with their low but constitutive production of some cytokines. A local instruction of the iNKT cell phenotype in polyps was also suggested by the fact that transfer of liver iNKT cells, which were predominantly iNKT1 (data not shown), to ApcMin/+ Jx18−/− mice reconstituted the polyp macrophage skewing toward M2 similar to what was found in ApcMin+/+ Jx18−/− mice. A different scenario was proposed in a recent publication demonstrating that unique features of the TCR could determine the development of iNKT cells with a phenotype of adipose iNKT cells in the thymus, followed by subsequent accumulation of these iNKT cells in adipose tissue.46 It remains to be investigated to what extent the tissue microenvironment induces the polyp iNKT.47 or adipose tissue phenotype of iNKT cells, and which signals may be required for the development of these unusual iNKT cell phenotypes.

The fact that iNKT cells have been shown to be protective in several tumor models has led to early clinical trials that have shown some promising outcomes in cancer patients who have received iNKT cell-directed therapy.47 Our results reveal novel aspects on iNKT cell regulation of tumor immunity, and encourage more detailed studies of the relative contributions of iNKT cells to antitumor immunity and immunoregulation in tumor immunity to fully understand their role and underlying mechanisms at different stages, and to evaluate the prospect of iNKT cell-directed therapy in these diseases.

METHODS

Mice. The ApcMin/+ mutation occurred and is maintained on the C57BL/6 genetic background.19 Sex- and age-matched mice were used in all experiments. ApcMin/+ mice were crossed with Jx18−/− mice to obtain ApcMin/+ Jx18−/− mice and littermate control ApcMin+ Jx18+/− mice. ApcMin/+ mice were also crossed with C1Dd−/− mice to obtain ApcMin+ C1Dd+−/− and littermate control ApcMin+ C1Dd+−/− mice. Both male and female mice from these crosses were used for experiments. All mice were bred and maintained at the department of Experimental Biomedicine, University of Gothenburg. Animal experiments in this study were approved by the animal ethics committee in Gothenburg.

Quantification of polyps. Mice were killed at 15 or 20 weeks of age. The intestines were flushed with phosphate-buffered saline (PBS) from both ends using blunt-end gavage needles to remove fecal material, and cut into three equal length segments: duodenum, jejunum, and ileum. Each segment was then cut open longitudinally and polyps were counted under stereomicroscope.

In vivo treatment with glycolipid. Mice were injected intraperitoneally with 4μg of glycolipids (α-GalCer C26:0 or α-GalCer C20:2) in 200 μl of PBS with a final concentration 0.1% dimethyl sulfoxide and 0.05% Tween-20. Vehicle control was prepared and injected in an identical manner. The 5-week-old female ApcMin−/− mice were treated with

Mucosal Immunology | VOLUME 11 NUMBER 1 | JANUARY 2018

141
glycolipids or vehicle control on day 1, 2, 7, 14, 21, 28, and 60, and the mice were killed at 15 weeks of age.

**Histology.** Tissue rolls of 12-week-old mouse intestine were fixed with formalin at room temperature for 24 h. After processing, the formalin-fixed, paraffin-embedded tissues were vertically sectioned lengthwise, and sections stained with hematoxylin and eosin (performed by Histo-Center AB, Västra Frölunda, Sweden).

**Lymphocyte preparation.** Spleen, MLN, and SI were collected from 15-week-old Apc 
\(^{-/-}\) or Apc 
\(^{+/+}\) x J218 
\(^{-/-}\) mice and their littermate control mice. Single-cell suspensions from the spleen and MLN were prepared. LP lymphocytes and tumor-infiltrating lymphocytes were isolated from the SI after removal of Peyer’s patches. The tissue was dissected into tumor and unaffected tissue to be processed separately. Unaffected tissue was cut into small pieces. Tumor and unaffected tissues were dissociated with Lamina Propria Dissociation Kit (Miltenyi Biotech, Bergisch Gladbach, Germany). Undigested tissue was removed by filtration and lymphocytes counted using trypan blue.

**Flow cytometry.** See Supplementary Material online.

**In vivo stimulation with αGalCer and serum cytokotyper determination.** αGalCer were first dissolved in 100% dimethyl sulfoxide, followed by a dilution with 0.5% Tween-PBS to achieve a stock concentration of 172.4 μg glycolipid per ml in 1% dimethyl sulfoxide and 0.5% Tween-PBS. This stock was stored at –20 °C. Upon use, the glycolipid stock was thawed and sonicated for 5 min and immediately heated at 80 °C for 2 min in glass vials. After vortexing for 1 min, the required volume of glycolipid stock was dissolved in prewarmed (37 °C) PBS and kept in an 80 °C bath until shortly before injection. Each mouse was injected intraperitoneally with 4 μg of αGalCer in 200 μl of PBS with a final concentration of 0.1% dimethyl sulfoxide 0.05% Tween-20. Mice were bled before 2GC injection, and at different times (2, 8, and 24 h respectively) after injection. Serum was prepared by centrifugation and stored at –20 °C. Cytokine content was measured using a CBA Mouse Th1/Th2/Th17 Cytokine Kit (BD Bioscience, Franklin Lakes, NJ) and the samples were analyzed with a LSRII Flow Cytometer (BD Bioscience).

**RNA isolation, cDNA synthesis and quantitative PCR.** See Supplementary Material.

**Quantitative RT² profiler PCR arrays.** The 384 (4 × 96)-well custom-made PCR array (SA Bioscience, Germantown, MD) layout contained four replicate primer assays for each of 86 target genes and 7 housekeeping genes. In addition, 4 wells contained mouse genomic DNA controls, and 12 wells contained positive PCR controls. Prepared cDNA from pools of five mice were added (for polyps in duplicates) to RT2 SYBR Green Mastermix and the mix was aliquoted into the PCR array plates. PCR reactions were performed by the Genomics Core Facility, The Sahlgrenska Academy, and relative expression levels were determined using data from the real-time cycle and the ΔΔCT method.

**INKT cell isolation and adoptive transfer.** Hepatic mononuclear cells (for hepatic mononuclear cell isolation see Supplementary Material) were stained with TCRβ and PBS57-loaded CD1d tetramer-PE and sorted with FACSAria II (BD). CD1d tetramer 
\(^{-/-}\) INKT cells (5 × 10⁵) or CD1d tetramer-negative TCRβ 
\(^{-/-}\) cells were injected intravenously into 13- and 14.5-week-old Apc 
\(^{-/-}\) x J218 
\(^{-/-}\) mice. Nontransferred mice were used as control. Mice were killed 3 weeks after the first injection. Lymphocytes from spleen, MLN, polyps, and unaffected lamina propria were isolated and analyzed with flow cytometry.

**Statistical analysis.** Calculation of statistical significance was performed using nonparametric Mann–Whitney test or two-way analysis of variance comparison with Bonferroni post-tests. P values of <0.05 were considered significant. Statistical analyses were performed on Prism GraphPad 6 (GraphPad Software, La Jolla, CA). Results are presented as mean ± s.d. in the figures.
