Abstract

TYK2 deficiency is a rare Primary Immunodeficiency disease caused by loss of function mutations of TYK2 gene, which is initially proposed as a subset of Hyper IgE syndrome (HIES). However, accumulating evidence suggest TYK2 deficient patients do not necessarily present with HIES characteristics, indicating a vacuum of knowledge on the exact roles of TYK2 in human immune system. Here we describe five more TYK2 deficient cases presenting with or without hyper IgE levels, atopy and distinct pathogen infection profile, which are caused by novel TYK2 mutations. These mutations were all found by high throughput sequencing and confirmed by Sanger sequencing. Pathogenic effects were confirmed by qRT-PCR and western blot. Peripheral blood mononuclear cells (PBMCs) from these patients showed heterogeneous responses to various cytokines treatment, including IFN-α/b/g, IL-6, IL-10, IL12 and IL-23. The homeostasis of lymphocytes is also disrupted. Based on our findings, we propose that TYK2 works as a multi-tasker in orchestrating various cytokines signaling pathways, differentially combined defects of which account for the expressed clinical manifestations.

Introduction

The non-receptor tyrosine kinase 2 (TYK2) is a member of the Janus kinase (JAK) family consisting of three additional members (JAK1-3). Cytokine binding to respective receptor complexes (type I or type II) activates JAKs, which subsequently phosphorylate intracellular receptor chain residues and activate a family of transcription factors termed signal transducers and activators of transcription (STATs, comprised of STAT1-4, STAT5A, STAT5B and STAT6) [1].

Within the JAK-STAT family of proteins, several primary immunodeficiencies have been described, ranging from autosomal recessive severe combined immunodeficiency (AR-SCID) in the case of JAK3 mutations, over a moderately severe phenotype in the case of autosomal dominant Hyper-IgE syndrome (AD-HIES) involving STAT3 mutations, to a heterogeneous clinical presentation in STAT1 deficiency with autosomal recessive Mendelian susceptibility to mycobacterial disease (AR-MSMD), and finally to a relatively mild phenotype in the case of TYK2 deficiency [2].

To date, there are 13 cases in total in English literature [3-8]. The first TYK2-deficiency patient was reported in 2006, a 22-years-old male Japanese, who displayed BCG lymphadenitis, S. aureus infections and recurrent viral infection, which were attributed to almost abolished responses of patient’s cells to IL-23, IL-12 and type I interferon (type I IFN) treatment, respectively [3]. Most interestingly, he also presented with the triad of signs characteristic of HIES: atopic dermatitis, high circulating IgE levels, and recurrent cutaneous staphylococcal infections, which led to the proposal that TYK2-deficiency should be a subset of AR-HIES. However, this notion was challenged lately by a comprehensive study of seven TYK2-deficiency patients showing normal IgE levels and absent of atopic dermatitis or cutaneous staphylococcal infection [4]. Later on, both HIES-like and non-HIES TYK2-deficiency cases were reported [5-8] and more confusingly, it has been shown identical TYK2 mutation can result in both HIES-like and non-HIES phenotypes [5-7]. Thus, more cases and further investigations are required to fully understand the nature of TYK2-deficiency.

Here, we present five cases of TYK2-deficiency with novel mutations from five unrelated Chinese families. Briefly, a 2+yr-old boy (P1) suffered from repeated pneumonia, stomatitis, perilabial herpes and thrush since the age of 3 months; a 3-yr-old boy (P2) suffered from recurrent respiratory tract infections and diarrhea since the age of 6 months; a 10-yr-old girl (P3) suffered from recurrent respiratory infection since 2 years old and she had a history of refractory eczema; a 5-yr-old boy (P4) suffered from recurrent suppurative otitis media and severe pneumonia and he also had a history of eczema and was highly allergic; a 5-yr-old boy (P5) suffered from recurrent pneumonia and refractory eczema and he also displayed hypothyroidism. By investigating these cases and comparing with previously reported cases, we aim to uncover a more complete picture of TYK2 deficiency.

Methods

Patients

The ethics committee of Children's Hospital of Chongqing Medical University approved the study. Written informed consent for participation in the study were obtained from patients' parents. Blood samples from patients and unaffected relatives were collected for molecular studies, which were performed in accordance with the Declaration of Helsinki.

Genetic Analyses

Genomic DNA were isolated from peripheral blood samples. Disease-causing mutations were screened using whole genome sequencing (WES) or targeted next generation sequencing (NGS) (MyGenostics, Inc. and Chigene, Inc.). Candidate mutations were confirmed by Sanger sequencing (primer sequences were listed Supplementary table 1).

Western blotting

PBMCs were stimulated with various cytokines for indicated time. The extracted protein were subjected to 10% SDS-PAGE and transferred onto PVDF membranes (Millipore). The following primary antibodies were used: rabbit anti-phosphorylated STAT1 (Cell Signaling Technology) and rabbit anti-STAT1 (Cell Signaling Technology), rabbit anti- phosphorylated STAT3 (Cell Signaling Technology), mouse anti-STAT3 (BD), rabbit anti-TYK2(Abcam, cat223733), and that against β-actin rabbit mAb horseradish peroxidase (HRP)-conjugated (Cell Signaling Technology). The HRP-conjugated goat anti-rabbit IgG secondary antibody (Cell Signaling Technology) and the HRP-conjugated goat anti-mouse IgG secondary antibody (ZSGB-BIO, China).

Flow Cytometry Assay

The following antibodies were used: CD3-PerCP (HIT3a), CD4-FITC (RPA-T4), CD8-BV510 ( RPA-T8), CD45RA-PE-Cy7 (HI100), CD27-APC ( M-T271), TCR aβ-PE (IP2b), TCR γδ-BV421 ( B1), CD19-APC ( HIB19), CD27-V450 ( M-T271), IgD-AF488 ( IA6-2), CD24-PE ( ML5), and CD38-PerCP ( HIT2), CD4-PE-Cy7 ( RPA-T4), CD8-PE
CXR5BV421 (J28ID4), CD25-APC (MT271,), CD127-PE (A019D5,), CCR6-PE (G034E3,), CD25-BV421 (BC96,), Helix-PerCP-cy5.5 (22F6,), CD19-PerCP-Cy5.5 (SJ25C1,), CD27-PE-cy7 (MT271). All were from Biolegend.

CD45RO-APC (UCHL1), CD45RA-FITC (HI100), CXCR3-APC (1C6), and FOXP3-PE (PCH101), CD152-APC (BNI3), IgM-APC (G20-127) and IFN-γ-APC (4S.B3). All were from BD Biosciences.

Patient 2 is a 3-yrs-old boy who suffered from recurrent respiratory tract infections and diarrhea since the age of 6 months. Pathogens found during multiple months (SupFig. 1C). Laboratory findings included mild elevated IgE level (330IU/mL, 516.3IU/mL) and positive viremia of EBV, CMV and HSV-1.

Th1 was defined as CD4⁺CD45RA⁻/CXCR5⁺/CXCR3⁺CCR6⁻, Th2 was defined as CD4⁺CD45RA⁻/CXCR5⁻/CXCR3⁻CCR6⁻, Th17 cells CD4⁺CD45RA⁻/CXCR5⁻/CXCR3⁻CCR6⁺, Th1-like cells CD4⁺CD45RA⁻/CXCR5⁺/CXCR3⁻CCR6⁻, Th2-like cells CD4⁺CD45RA⁻/CXCR5⁻/CXCR3⁻CCR6⁻, Th17-like cells CD4⁺CD45RA⁻/CXCR5⁺/CXCR3⁻CCR6⁺, T follicular helper cell CD3⁺CD4⁺/CD45RA⁻/CXCR5⁺, circulating follicular regulatory T cells CD3⁺CD4⁺/CD8⁺/FoxP3⁺/IgM⁺ B cells (CD19⁺/CD27⁺/IgM⁺), MZ-like B (CD19⁺/CD27⁺/IgM⁺), switched-memory B (CD19⁺/CD27⁺/IgM⁺).

The intracellular production of IFN-γ was investigated in PBMCs by flow cytometry. PBMCs (2 × 10⁶ cells/ml) were either unstimulated or stimulated with BCG (MOI = 20) or 100 ng/ml BCG + IL-12 for 48h, in 24-well plates. All the samples were treated with 1 μg/ml GolgiPlug (BD) for the last 6 h of culture.

The staining was performed according to manufacturers’ guides. The samples were acquired on a FACSCanto II flow cytometer, and the data were analyzed using FlowJo.

Real-Time Quantitative PCR

Total RNA was extracted from peripheral blood with the Blood Total RNA Miniprep Kit (Axygen). The cDNA was transcribed by the Transcriptor cDNA Synth. Kit (Roche). Levels of targeted mRNA were determined using a Bio-rad CFX96 Touch (BIO-RAD) machine. The results of each gene were determined with the 2−ΔΔCt method, and data was expressed as fold induction. Primers were listed in Supplementary table 2.

Construction of plasmids

Full length human TYK2 cDNA template (NM003331) was purchased from YouBio (G114136), Shanghai China and subcloned to 7.1-3×Flag-CMV expression plasmid as wild type TYK2 (WT) using Seamless Cloning kit from Biomed (CL116), Beijing China. Various missense and nonsense mutation mutants of TYK2 were generated by PCR method using WT as template. Mutations were confirmed by Sanger sequencing.

Cycloheximide Chase Assay

This assay is adapted from previous report[9]. Briefly, HEK293T cells were plated and transfected with various WT and mutant expression plasmids. 24 hours later, cycloheximide was added (1μg/ml) and cells were collected at different time point for western blot detection.

mRNA Stability Assay

This assay is adapted from previous report[10]. Briefly, HEK293T cells were plated and transfected with various WT and mutant expression plasmids. 24 hours later, Actinomycin D was added (100ng/ml) and cells were collected at different time point for qRT-PCR quantification.

Analysis of TCR-Vβ Diversity

Each TCR-Vβ fragment was amplified by Vβ- specific primer and a S'FAM- labeled primer which was described previously[11]. The PCR system consisted of cDNA, 1 μL; upstream and downstream primers of TCR-Vβ-FAM, 0.5 μL respectively (the primer concentration was 10 μmol/L); 2× Master Mix, 12.5 μL; and DEPC water, 10.5 μL. The amplification was conducted with denaturation for 1 min at 94 °C followed by 45 cycles of 65 °C for 15 s and 72 °C for 1 min. The target gene was sent to the Shanghai Sangon Biotech Company for further analysis. A complicated scoring system was used to assess the TCR-Vβ diversity (a score of less than 4 indicated a skewed subfamily).

Statistical analysis

Samples were compared using two-tailed, unpaired Student’s t-test with GraphPad Prism 7.00 if applicable, unless otherwise stated. Error bars were represented by SEM. *P < 0.05, **P < 0.01, ***P < 0.001, ****P < 0.0001.

Results

Clinical courses strongly favor a diagnosis of PID (Table 1).

Patient 1 is a 2+-yrs-old boy who suffered from perianal abscess at 26 days and repeated pneumonia, stomatitis (SupFig. 1A), perianal herpes (SupFig. 1B) and thrush since the age of 3 months. In addition, he also developed suppurative meningitis with unknown pathogen at 9 months old, salmonella enteritidis and hand-foot-and-mouth disease at 1 year old. He had a history of eczema and was allergic to pollen. He had received the following vaccinations: Bacille Calmette-Guérin (BCG); Hepatitis B, Polio, Diphtheria-pertussis-tetanus (DPT). BCG vaccination site was inflamed and purulent, and scab was formed after 9 months (SupFig. 1C). Laboratory findings included mild elevated IgE level (330IU/mL, 516.3IU/mL) and positive viremia of EBV, CMV and HSV-1.

Patient 2 is a 3-ys-old boy who suffered from recurrent respiratory tract infections and diarrhea since the age of 6 months. Pathogens found during multiple hospitalizations included Salmonella, Mycoplasma pneumoniae, and Mycobacterium Bovis BCG. No signs of viral or fungal infections were noticed. No high
serum IgE concentration, atopy, staphylococcal illness, or lymphopenia were found. Additionally, he also had language delay and was diagnosed of autism at the age of 3. Detailed clinical manifestations of this patient have been published elsewhere recently [8].

Patient 3 is a 10-yr-old girl who suffered from recurrent respiratory infection with unknown pathogens since she was 2 years old. She was vaccinated with hepatitis B, BCG, Polio, DPT and measles vaccines and showed no abnormal responses. She had a history of refractory eczema. Laboratory findings included low levels of immunoglobulin IgG 1.55g/L, IgA 0.0667g/L, IgM 0.172 g/L, IgE 0.6 IU/mL, increased eosinophils and negative evidence of *tubercle bacilli*.

Patient 4 is a 5-yr-old boy who suffered from recurrent suppurative otitis media and severe pneumonia. He was vaccinated with BCG and hepatitis B vaccine and there was pus at the BCG inoculation site. Pathogens found during multiple hospitalizations included *Staphylococcus haemolyticus, Staphylococcus epidermidis, Mycoplasma pneumoniae* and HSV-II. He had a history of eczema and was highly allergic. Laboratory findings included high level of IgE (756.83~1392 IU/mL) and increased eosinophils.

Patient 5 was a 5-yr-old boy who suffered from recurrent pneumonia with unknown pathogens and refractory eczema. BCG was injected immediately after birth and he also developed BCG-itis (SupFig. 1D). Laboratory findings included high level of IgE (1325~2030 IU/mL) increased eosinophils and negative evidence of TB infection. The patient also displayed secondary hypothyroidism: T3 1.55nmol/L, FT 33.71pmol/L, FT4 11.53pmol/L, TPOAb 177.1U/mL.

All patients were born to non-consanguineous and healthy parents. They were all clinically diagnosed with PID.

**Novel mutations identified by WES or targeted NGS lead to TYK2 deficiency**

The mutations were identified by whole exome sequencing (WES) for P1, P3 and P5 or targeted next generation sequencing (NGS, PID gene panel) for P2 and P4 (Fig. 1A-1C). P1 carried novel compound heterozygous mutations, c.3041T>C, p.L1014P (MAF: EXAC 0.000008; CADD score 32, pathogenic) and c.1253C>A, p.S418X (pathogenic) in TYK2 (Fig. 1D). P2 carried a novel homozygous mutation, c.2395G>A, p.G799R (MAF: EXAC 0.000008; CADD score 28.5, pathogenic) in TYK2 (Fig. 1D). P3 carried novel compound heterozygous mutations, c.1621G>A, p.G541R (MAF: EXAC 0.000058; CADD score 23, pathogenic) and c.704G>A, p.R235Q (MAF: EXAC 0.000114653; CADD score 22.4, pathogenic) in TYK2 (Fig. 1D). P4 carried compound heterozygous mutation, c.2269C>G, p.L757V (MAF: no recorded; CADD score 33, pathogenic) and c.1496delC, p.S50Cfsx2 (pathogenic) in TYK2 (Fig. 1D). P5 carried a novel homozygous mutation, c.1507C>T, p.R503X (pathogenic) in TYK2 (Fig. 1D). These mutations were all further confirmed by Sanger sequencing (Fig. 1D). According to inhouse prediction algorithm developed by the sequencing companies, these mutations were all predicted to be pathogenic to the expression or function of TYK2 protein (Fig. 1B and 1C). Other candidate variations in known PID genes were shown in supplementary table 3. To confirm this, we then determined the mRNA and protein levels of TYK2 in patients’ PBMCs and we found decreased mRNA levels (Fig. 1E-1G) and almost abolished expression of TYK2 (Fig. 1H-1K) in all patients except for P4, whose blood sample was not available. The anti-TYK2 antibody recognizes 200-400 amino acids of TYK2. It is worth mentioning that S418X truncated TYK2 generated in P2 and R503X truncated TYK2 generated in P5 were not detected at predicted location, too (Data not shown), indicating significantly decreased stability of the truncated proteins.

To further understand and confirm the pathogenicity of these mutations, we performed both Cycloheximide Chase Assay and mRNA Stability Assay to test the protein stability and mRNA stability, respectively. We found that these mutations indeed impaired the protein or mRNA stability or both (SupFig. 2). Please note that mutation in P2 has been tested to impaired the protein and mRNA stability previously [8]. Taken together, these five patients from five unrelated families all had TYK2 deficiency.

**TYK2-deficient PBMC showed divergent responses to IFN-a/b/g**

Type I IFNs signal through IFNAR1 and IFNAR2, which associate with TYK2 and JAK1, respectively. STAT1 and STAT2 are the major signal transducing STATs in response to type I IFNs [12,13]. Nevertheless, also all other STATs can be activated and contribute to responses in a cell type-specific manner. IFN-g signals through IFNGR1 and IFNGR2, which are associated with JAK1 and JAK2, respectively [14] and then STAT1 is activated. Often STAT3 [15,16] and sometimes STAT5 [17] are also activated by IFN-g. To further investigate the functional effects of TYK2 deficiency, we tested the responses of PBMC from TYK2-deficient patients to type I and type II interferons. For P1, the phosphorylation of STAT1 and STAT3 induced by IFN-a and IFN-b were both abolished, while the phosphorylation of STAT1 induced by IFN-g was comparable with that of healthy control (Fig. 2A). Reduced STAT1 expression is believed to be partially responsible for reduced phosphorylation of STAT1 in response to type I interferons in TYK2 deficient cells. Consistently, RT-qPCR showed decreased transcription of various ISGs (Fig. 2D). P2 also showed impaired responses to IFN-a/b but normal response to IFN-g (Fig. 2B), which was also consistent with ISG expression (Fig. 2E). Expression of STAT1 was almost abolished in PBMC from P2 (Fig. 2B), unlike P1 (Fig. 2A), who only showed reduced STAT1 expression. PBMC from P3 showed complex responses to interferons. Similar to P1 and P2, P3 showed normal response to IFN-g (Fig. 2C). However, we could not get consistent responses of P3 to IFN-a and P3 seemed to respond normally to IFN-b in terms of STAT1 phosphorylation (Fig. 2C). Meanwhile we could see impaired responses of P3 to IFN-a and IFN-b in terms of STAT3 phosphorylation (Fig. 2C). This complexity is reflected by the varied induction change of ISGs (Fig. 2F). Taken together, our data indicates that TYK2 deficiency results in divergent responses to IFN-a/b/g.

**TYK2-deficient PBMC showed divergent responses to IL-10 and IL-6**

IL-10 signals via IL-10R1 and IL-10R2, which associate with JAK1 and TYK2, respectively [18]. IL-6 can also induce phosphorylation of TYK2. Similarly, we assessed the responses of PBMC from TYK2-deficient patients to IL-10 and IL-6. PBMC from P1 showed intact response to IL-6 but abolished response to IL-10 as evidenced by the phosphorylation of STAT3 (Fig. 3A). PBMC from P2 showed significantly impaired responses to both IL-6 and IL-10 as evidenced by the phosphorylation of STAT3 (Fig. 3B) and the transcription of SOCS3 (Fig. 3C), a STAT3 target gene, in contrary to P3, whose responses to IL-10 and IL-6 seemed normal (Fig. 3D and 3E). These data again showed the role of TYK2 in IL-10 and IL-6 signaling was complicated as previously reported.

**TYK2-deficient PBMC showed similar responses to IL-12 and IL-23**
TYK2 associates with IL-12Rβ1, a receptor chain that is shared by IL-12 and IL-23. The second receptor chain for both cytokines (IL-12Rβ2 and IL-23R, respectively) associates with JAK2. Biological responses are mainly mediated by STAT4 in response to IL-12 and STAT3 in response to IL-23. We then assessed the responses of PBMC from TYK2-deficient patients to IL-12 and IL-23. In contrast to the responses to IL-6 and IL-10, PBMC from P2 and P3 showed similar impairment in response to IL-12 and IL-23 treatment (Fig. 4A-4D). Consistently, IFN-γ production by T cells from P3 was also much less compared to healthy control when treated with BCG alone or BCG plus IL-12 (Fig. 4E and 4F). Collectively, these data shown so far indicate TYK2 deficiency can lead to divergent clinical phenotypes possibly due to divergent signaling defects.

**TYK2 deficiency disturbs homeostasis of lymphocytes**

Cytokines signaling plays essential roles in controlling homeostasis of immune system. The impairment of various cytokines signaling in TYK2 deficient patients could lead to disruption of this balance. Indeed, we found decreased CD4+ T cells (especially CD4 naive cells) and total B cells, increased CD4 CM (central memory), CD4 EM (effector memory) cells, naive B cells and transitional B cells in P1 and P5 (Supplementary table 4). Subsets of T cells and B cells were normal in P2 (Supplementary table 4). Normal subsets of T cells were observed while decreased total B cells, memory B cells and plasmablasts B cells and increased naive B cells and the transitional B cells were noticed too in P3 (Supplementary table 4).

Further analysis of CD4+ T cell subsets showed that frequencies of Th1 and Th1-like cells were increased in P1 and P2 (Sup Fig. 3 and Fig. 5A-5F), while frequency of Th2 cells was decreased in P1, P2 and P3 compared to healthy controls (Fig. 5A-5F). Th17 cells seemed unaffected in all three patients tested. The frequencies of Th1 cells were elevated in P1 and P3, but normal in P2 (Fig. 5G). We further analyzed the Th1 subsets showing normal Tfr frequency and increased CXCR3+PD-1+ cells (Fig. 5H-5L and 5N). The proportion of Treg were comparable to that of healthy controls in P2 and P3, consistent with the expression of CTLA-4 and Helios (signature marker of Tregs), but increased in P3 (Fig. 5H-5L and Sup Fig. 4A, 4B). TCR repertoire seemed normal in three patients tested (Sup Fig. 5A-5D).

For B cell compartment, naive B cells were both elevated in P2 and P3. MZ-like cells and Sm-B cells were normal in P2, but decreased in P3 (Fig. 5M and 50-P).

**Discussion**

Clinical primary immunodeficiency cases caused by TYK2 mutations are very rarely reported. To our best knowledge, there are 13 cases in total in English literature not including ours. Because of this, the exact roles of TYK2 in the development, function and regulation of immune cells in human remain largely unknown. In clinical setting, it is extremely difficult to raise a specific suspicion of TYK2 deficiency when there is no clear full picture of its clinical manifestations which are closely related to the roles TYK2 plays in various immunologic processes. A recent study showed the P1104A TYK2 common variant predisposes host to mycobacteria infection by selectively disrupting IL-23–dependent antimycobacterial IFN-γ immunity, which also contributed to our understanding of TYK2 function. In this study, we presented five more cases of TYK2 deficiency and investigated many aspects of the effects TYK2 deficiency brings, which we think would further improve our understanding of TYK2 deficiency.

The first TYK2-deficient patient to be described was Japanese and had HIES as the main clinical feature, associated with numerous intracellular infections. Since then TYK2 deficiency was considered a subset of AR-HIES. However, newly identified TYK2 deficient patients did not necessarily present with hyper-IgE. A comprehensive comparison of various immunologic defects between the first reported patient and seven patients without hyper-IgE was reported, which proposed that intact IL-6/STAT3 signaling in patients without hyper-IgE might be responsible for this phenotypic difference. As defects in STAT3-mediated signaling play a key role in the development of HIES and IL-6 signaling is TYK2 independent in mice. Another TYK2 deficient patient without HIES was also reported to show normal IL-6 signaling and a TYK2 deficient patient with HIES showing impaired IL-6 signaling was reported (Table 1). Recently, autosomal recessive and dominant mutations in IL6ST, which encodes gp130, a subunit of cytokine receptor for IL-6, IL-11, IL-27 and some others, have been reported in patients with HIES. Thus, this idea seems to be plausible according to these previously reported cases. Surprisingly, however, our data did not support this hypothesis. As shown in Fig. 3, PBMC from P1 with mildly elevated IgE and P3 with low IgE both responded to IL-6 treatment normally in terms of STAT3 activation. Furthermore, PBMC from P2 with normal IgE level showed impaired response to IL-6 treatment. These findings strongly suggest the relation between hyper-IgE and TYK2 deficiency cannot be explained by dysregulated IL-6/STAT3 signaling.

Actually, mechanisms underlying increased IgE production are variable and complicated: a) enhanced class switching to IgE and the Th2 bias. B cell class switching to IgE is tightly regulated by interaction with CD4 T cells and the cytokine microenvironment. It is well established that IL-4 and IL-13, cytokines produced by Th2 cells and B cells, promote isotype class switching to IgE in B cells. Meanwhile, IL-10 and IL-21 act directly upon activated B cells to reduce the efficiency of class switching towards IgE. In addition, the engagement of CD40 on B cells by CD40L provides a second signal for IgE class switching. Th bias towards a Th2 phenotype can indirectly promote a cytokine milieu capable of enhancing IgE production. b) defects in general tolerance, meaning the Th2 response is increased concurrently with Th1 and Th17 responses in cases of catastrophic tolerance failure, which is seen in IPEX. Intriguingly, P1, P2 and P3 in our cohort all showed Th1 bias instead, with variable IgE levels, indicating involvement of other mechanisms. c) defects in barrier. While the majority of patients with atopy begin with elevated IgE, a minority of patients develop atopic dermatitis with normal IgE levels but experience elevated IgE after prolonged disease, indicating increased IgE levels can be a result of disrupted barriers. So, it seems that in the case of TYK2 deficiency, disrupted cytokines signaling network is key to the normal, increased or decreased IgE levels.

The viral infections can probably be accounted for by defects of IFN-a/b/g signaling. Similar to the first described TYK2 deficient patient, P1 in our cohort suffered repeated viral infection possibly due to abolished responses to IFN-a/b. Although impaired but not abolished IFN signaling does not necessarily lead to severe viral infection as the case of P2, P3 (Table 1) and previously reported cases.
IL-12 signaling induced IFN-γ production is believed to be responsible for the susceptibility to intracellular bacterial infection in TYK2 deficient patients, while IL-23 signaling induced IL-17 production for extracellular bacterial infection \[3\]. However, again our data present challenges to this notion as P3 showed no evidence of intracellular bacterial infection such as mycobacteria and salmonella in spite of impaired IL-12 signaling and P2 and P3 showed no evidence of extracellular bacterial infection such as *S. aureus* in spite of impaired IL-23 signaling.

Cytokine signaling not only affects the function of various immune cells but also plays essential roles in regulating homeostasis of immune system \[19\]. The effects of TYK2 deficiency on the homeostasis of lymphocytes compartment is unclear. In investigating this, we noticed that patients with elevated IgE (P1, P4 and P5) levels shared similar profile of disrupted T and B cell compartment and patient with normal IgE level (P2) shared similar profile of T cell compartment but distinct profile of B cell compartment with patient with low IgE level (P3).

The divergent cellular responses to cytokines, which is probably responsible for the divergent clinical phenotypes, might be resulted from residual expression of mutant TYK2. The effects of these mutations on TYK2 protein and mRNA stability could be due to disrupted post-translation modification of the protein and post-transcription modification of the mRNA.

In summary, we presented five more TYK2 deficiency cases caused by different novel mutations displaying divergent cellular defects and variable clinical phenotypes, which demonstrated that the correlation of cellular defects and clinical phenotypes is far more complicated than previously thought. In view of this, here we propose a new model that TYK2 works as a multi-tasker in orchestrating various cytokines signaling pathways, differentially combined defects of which account for the expressed clinical manifestations. Furthermore, we speculated that the discrepancies in cellular defects could at least partially be explained by different mutational effects to TYK2 protein, which needs to be investigated in the future. Nevertheless, our findings might lead us further towards a more accurate understanding of TYK2 function in human immune system and a more timely diagnosis of TYK2 deficient patients.

**Declarations**

**Acknowledgements**

We are grateful to all the patients and their families for their continuous corporation in this study. We thank the members of the laboratory for their technical assistance. We thank doctors and nurses for their generous supporting this project.

**Ethical Approval**

The ethics committee of Children's Hospital of Chongqing Medical University approved the study.

Blood samples collection were performed in accordance with the Declaration of Helsinki.

**Consent to Participate**

Written informed consent for participation in the study were obtained from patients' parents.

**Consent to Publish**

Written informed consent for publication of the study were obtained from patients' parents.

**Authorship Contributions**

G.L, HQ.D and ZX.D designed the study, wrote and revised the manuscript; G.L, X.D, T.Z and W.W performed the experiments and analyzed the data; G.L, LN.Z, YF.A, TY.H, XM.T followed the patients; G.S contributed substantially to the revision of this manuscript by providing technical support and performed some of the experiment. all authors reviewed the manuscript and approved for submission before it was submitted.
