Abstract:
The aim of the study was to compare the course of Corylus pollen season in 2019 in 12 cities located in different regions of Poland: Szczecin, Bydgoszcz, Zielona Gora, Wroclaw, Opole, Sosnowiec, Cracow, Piotrkow Trybunalski, Warsaw, Lublin, Olsztyn, and Bialystok. The analyses were carried out with the volumetric method using Burkard or Lanzoni pollen samplers. The length of the pollen season was determined with the 95% method. The earliest onset of the season was recorded in Warsaw and Szczecin, and at the latest beginning was noted in Lublin. The highest maximum concentrations of Corylus pollen were recorded in Lublin (244 P/m³), while Olsztyn (65 P/m³) as well as Bialystok and Bydgoszcz (66 P/m³ in each) were characterized by the lowest values. The maximum daily concentration of Corylus pollen grains was recorded in 3 cities in the second decade of February (16–19.02) and in the other eight cities in the third decade of February (24–28.02). The exception was Bialystok, where the peak value was only noted on 5.03. The annual pollen sum reached the highest values in Lublin (1301 grains) and Wroclaw (1031 grains). The highest risk of allergy in individuals sensitive to the pollen of this taxon was found in Lublin, Wroclaw, and Piotrkow Trybunalski. In Lublin, the highest hazel pollen concentrations were recorded in the earlier years of the investigations as well.

Key words: aeroallergens, pollen concentration, risk of allergy, hazel, 2019

As a rule, the allergenic hazel pollen appears in the air in February; however, pollen release may take place even in January during sunny although sometimes relatively cold days. Hazel male flowers are resistant to temperatures below 0°C and can release pollen even at -12°C [1, 2]. Since the main hazel allergen (Cor a 1) represents the strongest pollen allergens and often shows cross reactions with allergens of birch and alder pollen as well as food allergens, i.e. those contained in hazelnuts, apples, pears, or peaches, monitoring this taxon is extremely important for both allergy sufferers and allergists [3, 4].
Not only the commonly growing wild *Corylus avellana* L. plants, but also the ornamental and horticultural cultivars originating from *C. avellana* var. *pontica* Winkl., *C. maxima* Mill., and *C. colurna* L., abundantly cultivated in Europe and in Poland are a source of hazel pollen [5, 6]. The area of hazelnut plantations has increased in recent years. The highest concentration of hazel crops is noted in Lublin Province (42.4% of the entire area of hazel plantations). Large areas of hazel orchards are located in Mazowieckie, Łódzkie, Świętokrzyskie, Małopolskie, and Podkarpackie Provinces as well [7]. The concentration of hazel pollen in urban agglomerations does not usually reach high values; however, the concentration of the pollen of this taxon can be high in suburban areas as well as near hazel orchards and allotment gardens [4].

**Aim**

The aim of the study was to compare the hazel pollen concentration in the air of selected cities in Poland in 2019.

**Material and method**

Airborne hazel pollen was monitored in Szczecin, Bydgoszcz, Zielona Gora, Wroclaw, Opole, Sosnowiec, Cracow, Piotrkow Trybunalski, Warsaw, Lublin, Olsztyn and Bialystok in 2019. Aeroplankton samples were collected with the volumetric method using Burkard or Lanzoni pollen samplers. Microscopic observations were performed on preparations obtained in a 7-day cycle with assessment of 24-hour periods. Pollen concentrations were expressed as the number of pollen grains in 1 m³ of air per day (P/m³). The annual sum of pollen grains was the highest concentration did not exceed the threshold value of 80 P/m³. The annual total count of pollen registered in 13 measurement stations was lower, i.e. on average 508 grains [2]. In 2019, the annual sum of pollen grains was the highest in Lublin (1301 grains) and the lowest in Bialystok (317 grains). A relatively high sum of pollen grains was also recorded in Wroclaw (1031 grains) and Piotrkow Trybunalski (933 grains).

**Results**

In Poland, in 2019, the hazel pollen season began on different days of February. The earliest onset of the season was recorded in Warsaw (5.02) and the latest start was noted in Lublin (18.02). The difference between the dates of the beginning of the hazel pollen season in these cities was almost two weeks. The pollen season in all cities ended in March (tab. 1). The earliest date of the end of the pollen season was 6.03 in Szczecin, while at the latest dates, i.e. 22.03 and 23.03, were recorded in eastern Poland (Lublin, Olsztyn, Bialystok). The highest pollen concentrations were recorded in Lublin. The maximum daily concentration of hazel pollen was estimated at 244 P/m³ in this city. A much lower seasonal maximum was found in Olsztyn, Bialystok, Bydgoszcz, and Warsaw, where it reached a similar range of 65–68 P/m³. The peak value was recorded between 16.02 (Szczecin) and 5.03 (Bialystok) (figs. 1–6). The seasonal maximum was noted on 19.02 in Cracow and Wroclaw and in the third decade of February in other cities (24–28.02). The greatest number of days with a pollen concentration exceeding the threshold value of 35 P/m³ was observed in Lublin and Wroclaw (10 days), Piotrkow Trybunalski (9 days), and Zielona Gora (8 days). In turn, only one day when this value was exceeded was recorded in Bialystok (tab. 1). The highest number of days with a threshold value exceeding 80 P/m³ was recorded in Lublin (4 days), followed by Wroclaw and Piotrkow Trybunalski (3 days), Zielona Gora and Cracow (2 days), Szczecin, Opole, and Sosnowiec (1 day). In the other cities, the pollen concentration did not exceed the threshold value of 80 P/m³. The annual sum of pollen grains was the highest in Lublin (1301 grains) and the lowest in Bialystok (317 grains). A relatively high sum of pollen grains was also recorded in Wroclaw (1031 grains) and Piotrkow Trybunalski (933 grains).

**Discussion**

The annual pollen grains sum calculated based on the results from 12 cities in Poland was an average 729 in 2019. This value is similar to the average (714 grains) for 13 measurement stations in 2017 [9, 10]. In turn, in 2018, the annual total count of pollen registered in 13 measurement stations was lower, i.e. on average 508 grains [2]. In 2019, the annual sum of pollen hazel was the highest in Lublin, compared with the data from the other 12 investigated cities, likewise in the previous years, e.g. 2017 [9] and 2018 [2]. The high concentrations of hazel pollen in Lublin Province are associated with the high number of plantations of these shrubs in this area [7]. As demonstrated by the comparison of the annual sum of hazel pollen grains in Lublin in 2016–2019, i.e. on average 1246 grains [2, 9, 11], and the annual pollen sum from 2001–2005 for the same city, i.e. on average 959 grains [12], the number of pollen grains increased by 30% of the pre-

vious value. An upward trend in the annual pollen sum and peak value of hazel was recorded in Cracow in 2001–2013 [13].

Substantially higher values of the annual hazel pollen sum have been recorded in other European countries. Skjøth et al. [14] have reported that the average value of this parameter from 457 research stations from EAN is 3239 grains. Corylus grows almost across entire Europe; from Scandinavia to central Spain and Italy. The highest concentrations of hazel pollen are noted in the Alpine region in France, Switzerland, and Austria [14]. This information may be important for travelers around Europe or tourists spending winter holidays in the Alps.

In 2019, the highest risk of allergy to hazel pollen was noted in Lublin, Wroclaw, and Piotrkow Trybunalski. A similar risk was reported for Lublin, Wroclaw, and Cracow in 2018 [2] and for Lublin and Opole in 2017 [9].

Substantially lower threshold values than those used in this study to calculate the allergy risk (35 P/m³ and 80 P/m³) were reported by Thibaudon [15] from France. As suggested by this author, allergy symptoms can develop already at a hazel pollen concentration from 6 to 13 grains/m³/24 h, which he describes as “low”.

Conclusions

In 2019, the earliest onset of the hazel pollen season was recorded in Warsaw and Szczecin. The highest values of the annual pollen sum and peak value were noted in Lublin, likewise in the previous years.

The highest risk of allergy to Corylus pollen was reported for Lublin, Wroclaw, and Piotrkow Trybunalski.
