1. Exoplanet Explorers

The K2 mission has successfully found ≈1000 new exoplanet candidates. Now with an enormous data set (≈400,000 stellar targets) that nearly doubles the source count of Kepler (Huber et al. 2016), data parsing provides a unique time intensive obstacle. The Exoplanet Explorers project, part of the Zooniverse platform, allows citizen scientists to help overcome the abundance of transit data (Christiansen et al. 2018). We make available 204,855 statistically significant dips in K2 light curves from campaigns 0–8, 10, and 12–14. We used the k2phot pipeline (Petigura et al. 2018) to remove the K2 systematics and searched for periodic transits using...
the TERRA search algorithm (Petigura et al. 2013). For training, each participant is shown an example of a real folded exoplanet transit light curve, with the expected model plotted over the data. The volunteer is then instructed to look for dips that provide a similar match to this basic transit model. Each folded light curve presented are assigned a "Yes" or "No" value by the citizen scientist, indicating their belief that the source of the dip is caused by a transiting exoplanet. This simple visual inspection helps create a targeted search of the K2 light curves.

2. Criteria for Selection

For selection within this catalog we require additional cuts to provide a more focused list of potential candidates. We only consider dips that have received a "Yes" vote by ≥90% of the reviewers. All sources have been reviewed by at least 20 citizen scientists. Furthermore, we remove planet candidates that have been previously noted on the ExoFOP website (as of 2019 February 20). To eliminate eclipsing binaries, we exclude candidates with an inferred planet radius $R_{pl} > 0.2 R_*$. An expert visual inspection of the fitted light curve is performed to further eliminate noisy and problematic fits. Strong V-shape transits have been removed. These grazing transits only provide a lower limit for the planetary radius, making it difficult to eliminate eclipsing binaries.

3. Fit Method

Utilizing the EMCEE algorithm (Foreman-Mackey et al. 2013), we maximize and sample the posterior of the 8 transit parameters. The fitted parameters are as follows: $R_{pl}/R_*$ (the radius ratio of the planet and star), planet period, $T_0$ (the center of the first detected transit), $a_{pl}/R_*$ (the ratio of the semimajor axis to stellar radius), $b$ (the impact parameter), two quadratic limb darkening parameters, and a floating flux normalization parameter. Each parameter is fit using a uniform prior, with the exception of the semimajor axis ratio ($a_{pl}/R_*$) and the two limb darkening parameters. Assuming a perfect initial measurement of period from the TERRA grid search, Kepler's law is used to derive a Gaussian prior for $a_{pl}/R_*$. The independent information of stellar radius and stellar mass are provided by Huber et al. (2016) with Gaia radius updates from Bailer-Jones et al. (2018). Since the uncertainty in mass and radius are non-negligible, this constraint is rather weak. The priors for the limb darkening parameters are calculated using a Monte Carlo interpolation of the appropriate Claret et al.
We use the BATMAN transit model (Kreidberg 2015) to fit the processed K2Phot light curves. Here a Gaussian likelihood function is implemented to fit the photometric data to the transit model. This transit fitting procedure is similar to that of Crossfield et al. (2016). The resulting parameters are provided in our supplementary blog.\textsuperscript{15}

4. Results

In Figure 1 we provide 28 new planet candidates that have been vetted by citizen scientists and expert astronomers. This catalog contains 9 likely rocky candidates ($R_{pl} \leq 2.0 \, R_\oplus$) and 19 gaseous candidates ($R_{pl} > 2.0 \, R_\oplus$). Within this list we find one multi-planet system (EPIC 246042088). These two sub-Neptune ($2.99 \pm 0.02 \, R_\oplus$ and $3.44 \pm 0.02 \, R_\oplus$) planets exist in a near 3:2 orbital resonance. The discovery of this multi-planet system is important in its addition to the list of known multi-planet systems within the K2 catalog, and more broadly in understanding the multiplicity distribution of the exoplanet population (Zink et al. 2019). The candidates on this list are anticipated to generate RV amplitudes of 0.2–18 m s$^{-1}$, many within the range accessible to current facilities.

![Figure 1. Planet orbital period vs. planet radius for our new candidate sample (filled circles) compared to previous K2 planet candidates (violet open circles) and confirmed planets (brown open circles) from the NASA Exoplanet Archive. Circle size indicates Kepler bandpass magnitude, and](https://iopscience.iop.org/article/10.3847/2515-5172/ab0a02/meta[3/1/2019 9:30:10 AM])
color of the new candidates indicates host star effective temperature. An
interactive version of this plot is available
at http://www.kevinkhu.com/ee.html. The data used to create this figure are
available.

We thank all of the 21,770 volunteers who have helped classify transits via
Exoplanet Explorers. The following users were unable to be contacted, but
also provided early classifications: Cleaver82, DarylW, garryway,
GeorgeHolbrook, Grayzer56, Ianbourns, jgraber, krbethune,
miguengambler, mwalden, mzslashx, Or2dee2, sona25, swiese, Toncent, and
willedwards45. This publication uses data generated via the Zooniverse.org
platform, development of which is funded by generous support, including a
Global Impact Award from Google, and by a grant from the Alfred P. Sloan
Foundation. This research has made use of the Exoplanet Follow-up
Observation Program website and the NASA Exoplanet Archive, which is
operated by the California Institute of Technology, under contract with the
National Aeronautics and Space Administration under the Exoplanet
Exploration Program.
