Abstract
The literature on reconstruction formulas for photoacoustic tomography is vast. The various reconstruction formulas differ in the measurement devices used and geometry on which the data are sampled. In standard photoacoustic imaging (PAI), the object under investigation is illuminated uniformly. Recently, sectional PAI techniques, using focusing techniques for initializing and measuring the pressure along a plane, appeared in the literature. This paper surveys existing and provides novel exact reconstruction formulas for sectional PAI.

1. Introduction

The literature on reconstruction formulas and back-projection algorithms for photoacoustic imaging (PAI) is vast. Wang et al developed reconstruction formulas for cylindrical, spherical and planar measurement geometries in a series of papers [27, 25, 28], and recently, many more algorithms based on reconstruction formulas have been developed (see the survey [13]).

Also, different measurement devices for the ultrasound pressure have been suggested. Most common are small detectors based on materials, which exhibit a strong piezoelectric effect and can be immersed safely in water (i.e. polymers such as PVDF). In analytical reconstruction formulas, they are considered point detectors. Other experimental setups have been realized with line and area detectors, which collect averaged pressure (see [23] for a survey).

Here, we consider the problem of photoacoustic sectional imaging. As opposed to standard PAI, where the detectors record sets of two-dimensional projection images from which the three-dimensional imaging data can be reconstructed, single-slice imaging reconstructs a set of two-dimensional slices, each by a single-scan procedure. The advantages of the latter approach are a considerable increase in measurement speed and the possibility of doing selective plane imaging. In general, this can only be obtained by the cost of decreased out-of-plane resolution (i.e. the direction orthogonal to the focusing plane). Experimentally, one
can obtain photoacoustic sectional imaging by illuminating a single plane of the object and by using a focused detector. Technical details are provided in section 2. In our experiments, the measurement data are recorded on a cylindrical domain $\partial\Omega \times \mathbb{R}$, where $\partial\Omega$ denotes the boundary of a smooth domain $\Omega$ in $\mathbb{R}^2$.

The difference in this model to previously studied models is that the wave propagation is considered fully three dimensional, and the initialization and measurements are fully two dimensional due to the selective plane illumination and detection. Therefore, such setups require novel reconstruction formulas. In particular, as a further novelty, we present reconstruction formulas in ellipsoidal domains.

This paper surveys existing and provides novel exact formulas for the reconstruction of the initial pressure distribution for various kinds of measurement setups. After the introduction of the universal back-projection algorithm introduced in [26], this goal seems superfluous, although not discussed in detail for sliced imaging. However, it has been shown recently by Natterer [17] that universal back-projection is only exact for special sampling geometries. Here, for sliced imaging and certain sampling setups, we can indeed find mathematically exact universal reconstruction algorithms for arbitrary strictly convex sampling domains $\Omega$.

The paper is organized as follows. In section 2, we describe the experimental setup of photoacoustic sectional imaging, and we model in section 3 various measurements where it is possible to derive exact reconstructions formulas for sectional imaging. The reconstruction formulas are then provided in section 4. In the appendix, we survey some background material on the Abel transform, the spherical mean operator and the Mathieu equation.

2. Experimental background

Below we give an overview on photoacoustic sectional imaging, describe the experimental realization and provide mathematical formulations. In contrast, we call conventional PAI with uniform illumination of the object non-focused.

In general, PAI is based on the so-called thermo- or photoacoustic effect. Laser light impinging onto a surface of an object leads to its heating, and under the conditions of thermal and stress confinement, an acoustic wave emerges from the object. Mathematically, this means that the initial pressure distribution $p_0$ is related to the absorption coefficient of the object by [3]

$$p_0(x) = \frac{\beta c^2}{C_p} \mu_a(x) \Phi(x),$$

(2.1)

where $x \in \mathbb{R}^3$. The constant prefactor consists of the thermal expansivity $\beta$, the specific heat capacity $C_p$ and the speed of sound $c$. Then, $\mu_a$ is the absorption coefficient of the object and $\Phi$ denotes the local light fluency. Neglecting effects of light propagation (i.e. setting $\Phi$ to be a constant), $\mu_a$ remains the only variable depending on $x$ and containing the desired tomographic information about the object. Reconstruction algorithms that also take light propagation into account are investigated in [3] but are not the focus of this work.

It is common to classify photoacoustic measurement setups into point (see, e.g., [12]) and integrating detector setups [2]. The focus of this paper is reconstruction methods for sectional imaging and various kinds of detectors.

In conventional photoacoustic setups with point detectors, measurements are collected (see figure 1) all over a surface enclosing the object (i.e. a sphere or an ellipsoid), or all over a sufficiently large cylindrical surface (where the cross-section can be every line segment), or over a sufficiently large plane. The latter two detector array geometries allow for approximate reconstructions only, since sufficiently large means that in theory the array is considered...
Figure 1. Sketch of non-focused point-detector arrays: (a) closed surface, (b) quasi-infinite plane and (c) cylindrical surface. The point detectors are spread over the indicated surfaces (points are not drawn in the figure). The detector arrays (b) and (c) suffer from the limited-view problem.

Figure 2. Sketch of non-focused line-detector arrays: (a) quasi-infinite plane and (b) cylindrical surface with arbitrary cross-section. The detector array (a) suffers from the limited view problem.

infinently large. This approximation causes the limited view problem in practical applications. Paltauf et al have given correction factors for some of the affected geometries [22].

The linear and planar detectors have to be moved tangentially to a surface surrounding the object (see [2]). Practically, this only allows the measurement devices to be aligned on a cylindrical surface (or on a plane). Experimental realizations of line detectors are documented for instance in [23].

In the following, we explain the principles of focusing detectors. The ultrasonic wave is refracted by a suitable acoustic lens such that out-of-plane signals are generally weak and can be neglected. Thus, only signals emerging from the desired imaging plane are collected at the detector. Contemporary focusing ultrasonic detectors have a spherical or cylindrical shape; thus, the detector surface plays the role of the acoustic lens. We consider the case of a cylindrically focusing detector, which focuses into a plane. The sectional imaging can be improved further by illuminating the desired plane only, i.e. by cylindrical lenses in front of the object. Note, however, that this requires a low-scattering coefficient of the sample, because otherwise illumination will not be restricted to a single plane. The achieved out-of-plane
resolutions are worse than the in-plane resolutions nevertheless. For more details on focusing point detectors, see [15, 24], and for focusing line detectors, see [7, 8].

3. Mathematical formulation

As an idealized model for the photoacoustic sectional imaging problem, we assume that the laser pulse, which illuminates the sample, is perfectly focused on the plane \( \{ x \in \mathbb{R}^3 \mid x_3 = 0 \} \). We further consider the absorption of the laser light and the hereby caused expansion of the material to happen instanteneously, so that the induced initial pressure distribution \( p_0 : \mathbb{R}^3 \to \mathbb{R} \) can be considered to be of the form

\[
p_0(\xi, z) = \hat{p}_0(\xi) \delta(z), \quad \xi \in \mathbb{R}^2, \quad z \in \mathbb{R},
\]

for some smooth function \( \hat{p}_0 : \mathbb{R}^2 \to \mathbb{R} \) and with \( \delta \) denoting the Dirac delta function. It will thus be often convenient for us to write a point \( x \in \mathbb{R}^3 \) in the form \( x = (\xi, z) \) with \( \xi \in \mathbb{R}^2 \) and \( z \in \mathbb{R} \).

This initial pressure distribution \( p_0 \) now initiates a pressure wave inside the object. Let \( p(x; t) \) denote the pressure at the point \( x \in \mathbb{R}^3 \) at the time \( t \in [0, \infty) \) after the laser pulse. For the propagation of the wave, we neglect the different material properties in the object and simply assume that the pressure distribution \( p : \mathbb{R}^3 \times [0, \infty) \to \mathbb{R} \) obeys the linear three-dimensional wave equation with constant speed of sound, which we normalize to 1:

\[
\begin{align*}
\partial_{tt} p(\xi, z; t) &= \Delta_{\xi, z} p(\xi, z; t), \\
\partial_t p(\xi, z; 0) &= 0, \\
p(\xi, z; 0) &= p_0(\xi, z) = \hat{p}_0(\xi) \delta(z)
\end{align*}
\]

for all \( \xi \in \mathbb{R}^2, \quad z \in \mathbb{R} \) and \( t > 0 \). Here, \( \Delta_{\xi, z} = \partial_{\xi_1}^2 + \partial_{\xi_2}^2 + \partial_z^2 \) denotes the three-dimensional Laplacian in Euclidean coordinates.

Our aim is to recover the function \( \hat{p}_0 \), describing the initial pressure distribution, from certain measurements of the pressure wave \( p \). From the initial pressure distribution, we may then determine the absorption coefficient \( \mu_a \) of the object by using relation (2.1), which is the final goal of the measurement.

The position of the detectors performing these measurements shall be given by the boundary \( \partial \Omega \) of a convex domain \( \Omega \subset \mathbb{R}^2 \) in the illumination plane, where we additionally assume that \( \hat{p}_0 \) has compact support in \( \Omega \).

In practical realizations, the detectors usually have a special convex shape so that they mainly detect the pressure waves originating from the illumination plane and try to suppress those parts coming from an excitation outside this plane, as illustrated in section 2. But since we assume a perfect focusing of the initial pressure distribution on the illumination plane in our model, we do not need this additional focusing by the detectors and will use simpler detector geometries. In a more realistic model, however, this suppression of signals from outside the illumination plane should be in some way incorporated into the mathematical model.

We will consider the following four different measurement setups and derive reconstruction formulas. Some of the reconstruction formulas and setups have already been documented in the literature and are surveyed here in the general context. Most of the formulas, however, are new.

**Vertical line detectors:** The measurement data are

\[
m_1(\xi; t) := \int_{-\infty}^{\infty} p(\xi, z; t) \, dz
\]

for all \( \xi \in \partial \Omega, \quad t > 0 \).
That is, in practical realizations, we use line detectors, which measure the overall pressure along a line orthogonal to the illumination plane.

**Point detectors:** The measurement data are

\[
m_2(\xi; t) := p(\xi, 0; t) \\
\text{for all } \xi \in \partial \Omega, \quad t > 0.
\] (3.4)

That is, we use point detectors, which measure the pressure on the boundary of \( \partial \Omega \) over time. This measurement geometry is used in [15, 24].

For the other two measurement methods, we additionally impose that the domain \( \Omega \subset \mathbb{R}^2 \) is strictly convex and bounded.

**Vertical plane detectors:** The measurement data are

\[
m_3(\theta; t) := \int_{P(\theta)} p(x; t) \, ds(x) \\
\text{for all } \theta \in S^1, \quad t > 0,
\] (3.5)

where \( P(\theta) \subset \mathbb{R}^3 \) denotes the tangential plane of the cylinder \( \partial \Omega \times \mathbb{R} \) orthogonal to the vector \( (\theta, 0) \), see (3.8). For a practical realization, we use planar detectors, which are moved tangentially to \( \partial \Omega \) around the object and measure the averaged pressure on the plane.

**Horizontal line detectors:** The measurement data are

\[
m_4(\theta; t) := \int_{T(\theta)} p(\xi; 0; t) \, ds(\xi) \\
\text{for all } \theta \in S^1, \quad t > 0,
\] (3.6)

where \( T(\theta) \subset \mathbb{R}^2 \) denotes the tangential line of \( \partial \Omega \) orthogonal to the vector \( \theta \); see (3.7). This is a realization using line detectors, which measure the overall pressure on a line tangential to \( \partial \Omega \) in the illumination plane; see [7–9]. (In these papers, they used for the reconstruction a phenomenologically motivated formula whose structure is very similar to formula (4.13), which we derive for this sort of measurements.)

In those cases where the domain \( \Omega \) is strictly convex and bounded, we parametrize the boundary \( \partial \Omega \) with the map \( \xi : S^1 \to \partial \Omega \), which associates with every unit vector \( \theta \in S^1 \) the point \( \xi(\theta) \in \partial \Omega \), where the outward unit normal vector of \( \partial \Omega \) coincides with \( \theta \); see figure 3.

Since the tangent line \( T(\theta) \) of \( \partial \Omega \) at \( \xi(\theta) \) is thus by definition orthogonal to \( \theta \), we can define the family \( T(r, \theta), \ r \in \mathbb{R}, \) of lines parallel to the tangent \( T(\theta) \) by

\[
T(r, \theta) = \xi(\theta) + r\theta + \mathbb{R}\theta^\perp \subset \mathbb{R}^2, \quad T(\theta) = T(0, \theta),
\] (3.7)

for every \( \theta \in S^1 \) and \( r \in \mathbb{R} \). Here, \( \theta^\perp \in S^1 \) denotes a unit vector orthogonal to \( \theta \).
Moreover, we introduce the family $P(r, \theta)$, $r \in \mathbb{R}$, of planes parallel to the tangent plane $P(\theta)$ of the cylinder $\partial \Omega \times \mathbb{R}$ at $(\zeta(\theta), 0)$ by

$$P(r, \theta) = (T(\theta), 0) + (0, R) \subset \mathbb{R}^3, \quad P(\theta) = P(0, \theta),$$

for every $\theta \in S^1$ and $r \in \mathbb{R}$.

### 4. Reconstruction methods

In the following, we derive universal reconstruction formulas for photoacoustic sectional imaging. Conceptually, the paper is closely related to [14], where universal formulas for conventional photoacoustic tomography were derived in arbitrary geometry. However, some of the results there are implicit, requiring explicit knowledge of eigenfunctions, which are provided here explicitly. In addition, the focus of this paper is on sectional imaging, which results in different formulas.

#### 4.1. Measurements with vertical line detectors

We introduce the function

$$\tilde{p}(\xi; t) = \int_{-\infty}^{\infty} p(\xi, z; t) \, dz, \quad \xi \in \mathbb{R}^2, \quad t \geq 0.$$  

(4.1)

Then, the initial value problem (3.2) for the function $p$ implies that the function $\tilde{p}$ satisfies the two-dimensional wave equation:

$$\partial_{tt} \tilde{p}(\xi; t) = \Delta_\xi \tilde{p}(\xi; t) \quad \text{for all} \quad \xi \in \mathbb{R}^2, \quad t > 0,$$

with the initial conditions

$$\partial_t \tilde{p}(\xi; 0) = 0 \quad \text{for all} \quad \xi \in \mathbb{R}^2,$$

$$\tilde{p}(\xi; 0) = \hat{p}_0(\xi) \quad \text{for all} \quad \xi \in \mathbb{R}^2.$$  

The initially three-dimensional reconstruction problem therefore reduces to the two-dimensional problem of calculating $\hat{p}_0(\xi) = \tilde{p}(\xi; 0)$, $\xi \in \mathbb{R}^2$, from the measurement data

$$m_1(\xi; t) = \tilde{p}(\xi; t), \quad \xi \in \partial \Omega, \quad t > 0.$$  

#### 4.1.1. Reconstruction formulas based on series expansions.

For special domains $\Omega$, explicit reconstruction formulas are known: see the review [10] for $\Omega$ a circle and the half-space. The derivation for the ellipse is published in [4].

- If $\Omega$ is the half-space $\{\xi \in \mathbb{R}^2 \mid \xi_2 > 0\}$, we obtain [11]

$$\hat{p}_0(\xi) = \frac{2}{\pi} \int_{-\infty}^{\infty} \int_{k}^{\infty} \tilde{m}_1(k, \omega) e^{ik\xi_1} \cos(\xi_2\sqrt{\omega^2 - k^2}) \, d\omega \, dk$$

(4.2)

for every $\xi \in \mathbb{R}^2$, where

$$\tilde{m}_1(k, \omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} \int_{0}^{\infty} m_1(\xi_1, 0; t) e^{-ik\xi_1} \cos(\omega t) \, d\xi_1 \, dt$$

is the Fourier-cosine transform of the measurement data $m_1$.  

6
If $\Omega = B_R^2(0)$ is the two-dimensional ball with radius $R$ and center 0, we choose $\psi : [0, \infty) \times [0, 2\pi) \to \mathbb{R}^2$, $\psi(r, \varphi) = (r \cos \varphi, r \sin \varphi)$ and obtain \cite{10}

$$\hat{p}_0(\psi(r, \varphi)) = \frac{1}{\pi} \int_0^\infty \sum_{k=-\infty}^{\infty} \frac{J_k(R\omega)}{J_k(\omega)} \tilde{m}_1(k, \omega) e^{i\omega \varphi} \, d\omega$$

(4.3)

for every $r \in [0, \infty)$ and $\varphi \in [0, 2\pi)$, where

$$\tilde{m}_1(k, \omega) = \frac{1}{\pi} \int_0^\infty \int_0^{2\pi} m_1(\psi(R, \varphi); t) e^{-ik\varphi} \cos(\omega t) \, d\varphi \, dt$$

is the Fourier–cosine transform of the measurement data $m_1$. Here, $J_k, k \in \mathbb{N}_0$, denotes the $k$th Bessel function.

Equations (4.3) and (4.2) can be derived from formulas for the inversion of the spherical mean operator (see appendix A.2), and this is why these formulas are typically assigned to Norton \cite{18} and Norton and Linzer \cite{19}, although they considered reflectivity ultrasound imaging, and here, the topic is photoacoustics.

If $\Omega$ is the ellipse $\{ \xi \in \mathbb{R}^2 \mid \frac{x^2}{a^2} + \frac{y^2}{b^2} < 1 \}$ with $a > b$, we set

$$\psi : [0, \infty) \times [0, 2\pi) \to \mathbb{R}^2, \quad \psi(r, \varphi) = \xi \left( \frac{\cosh(r \cos \varphi)}{\sinh(r \sin \varphi)} \right),$$

with the linear eccentricity $\varepsilon = \sqrt{a^2 - b^2}$ and find \cite{4}

$$\hat{p}_0(\psi(r, \varphi)) = \frac{\sqrt{2}}{\pi} \int_0^\infty \sum_{k=0}^{\infty} \frac{R_k(r; \omega)}{R_k(r_0; \omega)} \tilde{m}_1(k, \omega) \Phi_k(\psi; \omega) \, d\omega,$$

where $r_0 = \operatorname{artanh}(\frac{a}{b})$ is chosen such that $\psi(r_0, \varphi) \in \partial \Omega$ and

$$\tilde{m}_1(k, \omega) = \frac{\sqrt{2}}{\pi} \int_0^\infty \int_0^{2\pi} m_1(\psi(r_0, \varphi); t) \Phi_k(\psi; \omega) \cos(\omega t) \, d\varphi \, dt.$$

Herein, the functions $\Phi_k$ are for $k \in \mathbb{N}_0$ defined by

$$\Phi_{2k}(\psi; \omega) = \cos_k \left( \sqrt{\frac{\varepsilon^2 \omega^2}{4}} \right) \quad \text{and} \quad \Phi_{2k+1}(\psi; \omega) = \sin_k \left( \sqrt{\frac{\varepsilon^2 \omega^2}{4}} \right),$$

where $\cos_k$ and $\sin_k$ denote the Mathieu cosine and Mathieu sine functions, respectively (see appendix A.4) and the functions $R_k$ are the corresponding solutions of the radial Mathieu equation and are for $k \in \mathbb{N}_0$ given by

$$R_{2k}(r; \omega) = \cos_k \left( \sqrt{i \varepsilon^2 \omega^2} \right) \quad \text{and} \quad R_{2k+1}(r; \omega) = -i \sin_k \left( \sqrt{i \varepsilon^2 \omega^2} \right).$$

### 4.1.2. Reduction to the spherical mean operator

Taking into account relation (A.8) between the solution of the two-dimensional wave equation and the spherical mean operator, the problem of determining $\hat{p}_0$ from the measurements $m_1(\xi; t) = \hat{p}(\xi; t)$ for $\xi \in \partial \Omega, t > 0$ can be equivalently described as the problem of reconstructing $\hat{p}_0$ from the spherical mean operator $\hat{M}_2[\hat{p}_0](\eta; r)$ of $\hat{p}_0$ for $\xi \in \partial \Omega$ and $r \in (0, \infty)$.
• For $\Omega = B^3_1(0) \subset \mathbb{R}^3$, analytical reconstruction formulas have been derived by Finch et al [6] and read as follows:

$$
\hat{p}_0(\xi) = \frac{1}{2\pi} \Delta \xi \left( \int_0^{2\pi} \int_0^R rM_{2}[\hat{p}_0](R\theta, r) \log |r^2 - |\xi - R\theta|^2| \, dr \, ds(\theta) \right)
$$

(4.4)

and

$$
\hat{p}_0(\xi) = \frac{1}{2\pi} \int_{S^1} \int_0^R (\partial_r r \partial_r M_{[\hat{p}_0]}(R\theta, r) \log |r^2 - |\xi - R\theta|^2| \, dr \, ds(\theta).
$$

(4.5)

• Recently, Palamodov derived in a more general setup analytical reconstruction formulas for some further special geometries. For $\Omega$ being, e.g., the ellipse whose boundary is parametrized by the function $\psi : S^1 \to \mathbb{R}^2$, $\psi(\theta) = (a_1 \theta_1, a_2 \theta_2)$, $a_1, a_2 \in (0, \infty)$, he found the reconstruction formula

$$
\hat{p}_0(\xi) = -\frac{4}{\int_{S^1} |\xi - \psi(\theta)|^{-2} \, ds(\theta)} \int_{S^1} \int_{-\infty}^{\infty} r^2 M_{2}[\hat{p}_0](\psi(\theta), r^2) \left( |\xi - \psi(\theta)|^2 - r^2 \right)^2 \, dr \, ds(\theta),
$$

see [20, 21].

• For a general domain $\Omega$, Kunyansky reduced in [14] the reconstruction problem to the determination of the eigenvalues $\lambda_k$ and normalized eigenfunctions $u_k$, $\|u_k\|_2 = 1$, of the Dirichlet Laplacian $-\Delta$ on $\Omega$ with zero boundary conditions:

$$
\Delta u_k(\xi) + \lambda_k u_k(\xi) = 0, \quad \xi \in \Omega,
$$

(6.6)

$$
u_u(\xi) = 0, \quad \xi \in \partial \Omega.
$$

(6.7)

Indeed, if $(\xi, \eta) \mapsto G_{\lambda_k}(|\xi - \eta|)$ is a free-space rotationally invariant Green’s function of the Helmholtz equation (4.6) and $n(\xi)$ denotes the outer unit normal vector of $\partial \Omega$ at $\xi \in \partial \Omega$, then

$$
\hat{p}_0(\xi) = 2\pi \sum_{k=0}^{\infty} \tilde{M}_k u_k(\xi),
$$

(6.8)

where

$$
\tilde{M}_k = \int_{\Omega} \int_{0}^{\infty} rM_{2}[\hat{p}_0](\eta, r)G_{\lambda_k}(r) \langle \nabla u_k(\eta), n(\eta) \rangle \, dr \, ds(\eta).
$$

We thus obtain the initial pressure distribution $\hat{p}_0$ by first calculating from the measurements $m_t(\xi; t) = \hat{p}(\xi; t)$, $\xi \in \partial \Omega$, $t > 0$, with formula (A.8), the spherical mean operator $M_2[\hat{p}_0](\xi; r)$ of $\hat{p}_0$ for $\xi \in \partial \Omega$ and $r \in (0, \infty)$, and then, using one of the formulas (4.4), (4.5), or (4.8) to obtain $\hat{p}_0$.

4.2. Measurements with point detectors

From equation (A.7), we know that the solution of the initial value problem (3.2) can be for every $x \in \mathbb{R}^3$ and $t > 0$ written in the form

$$
p(x, t) = \partial_t \left( \frac{1}{4\pi t} \int_{\partial B^3_1(0)} f(x + y) \, ds(y) \right).
$$

Parameterizing the sphere $\partial B^3_1(0)$ in cylindrical coordinates, i.e. in the form

$$
\partial B^3_1(0) = \{(\sqrt{t^2 - h^2}, h) : h \in [-t, t], \theta \in S^1\},
$$
we find for every $x = (\xi, z), \xi \in \mathbb{R}^2, z \in \mathbb{R}$, and $t > 0$, that

$$p(\xi, z; t) = \frac{1}{4\pi t} \int_{\mathbb{S}^1} \hat{p}_0(\xi + \sqrt{t^2 - h^2}) \delta(z + h) ds(\theta) dh,$$

where we have used the special property of the source term (3.1). Integrating out the $\delta$-distribution, we obtain for every $z \in [-t, t]$

$$p(\xi, z; t) = \frac{1}{4\pi t} \int_{\mathbb{S}^1} \hat{p}_0(\xi + \sqrt{t^2 - z^2}) ds(\theta).$$ (4.9)

By the definition (A.4) of the spherical mean operator $M_2$, this means

$$p(\xi, z; t) = \frac{1}{2} \hat{p}_0(M_2[\hat{p}_0](\xi; \sqrt{t^2 - z^2})) \quad \text{for} \quad z \in [-t, t].$$ (4.10)

From the assumption that the support of $\hat{p}_0$ lies completely in $\Omega$, we know that $M_2[\hat{p}_0](\xi; 0) = \hat{p}_0(\xi) = 0$ for $\xi \notin \Omega$. Thus, we can integrate relation (4.10) for $\xi \notin \Omega$ and find for every $z \in [-t, t]$ that

$$M_2[\hat{p}_0](\xi; \sqrt{t^2 - z^2}) = 2 \int_{\Xi} p(\xi, z; \tilde{t}) d\tilde{t}.$$

Setting $z = 0$, we obtain for every $\xi \in \partial \Omega$ and every $t > 0$ the relation

$$M_2[\hat{p}_0](\xi; t) = 2 \int_{0}^{t} m_2(\xi; \tilde{t}) d\tilde{t}.$$

Having calculated the spherical mean of $\hat{p}_0$, we can now proceed as in section 4.1.2.

4.3. Measurements with vertical plane detectors

For every $\theta \in S^1$, we define for $r \in \mathbb{R}$ and $t \geq 0$ the function

$$\tilde{p}_0(r; t) = \int_{P(r, \theta)} P(x; z) ds(x),$$

where $P(r, \theta)$ denotes the plane as defined in (3.8).

Then, since the vectors $(\theta, 0), (\theta^+, 0)$ and $(0, 0, 1)$ form an orthonormal basis of $\mathbb{R}^3$ and the Laplacian is rotationally invariant, we find from equation (3.2) that

$$\partial_t \tilde{p}_0(r; t) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \Delta_x P(\xi(\theta) + r\theta + u\theta^+, z; t) du dz = \partial_r \tilde{p}_0(r; t)$$

for every $r \in \mathbb{R}$ and $t > 0$. Thus, $\tilde{p}_0$ solves the one-dimensional wave equation with the initial conditions

$$\partial_t \tilde{p}_0(r; 0) = 0 \quad \text{for all} \quad r \in \mathbb{R} \quad \text{and}$$

$$\tilde{p}_0(0; t) = m_1(\theta; t) \quad \text{for all} \quad t > 0$$

resulting from (3.2) and (3.5), respectively. Moreover, since $\tilde{p}_0$ has its support inside $\Omega$, we know that $\tilde{p}_0(r; 0) = 0$ for $r \geq 0$.

With d’Alambert’s formula for the solution of the one-dimensional wave equation, we find that the unique solution for this initial value problem is given by

$$\tilde{p}_0(r; t) = m_1(\theta; -t - r) + m_1(\theta; t - r), \quad r \in \mathbb{R}, \quad t > 0,$$

where we set $m_1(\theta; t) = 0$ for $t \leq 0$.

Finally, we have to recover from the values of $\tilde{p}_0, \theta \in S^1$, the initial pressure distribution $p_0$ from equation (3.2). We have the relation

$$\tilde{p}_0(r; 0) = \int_{-\infty}^{\infty} \tilde{p}_0(\xi(\theta) + r\theta + u\theta^+) du = \mathcal{R}[\hat{p}_0](r + \langle \xi(\theta), \theta \rangle, \theta).$$
where $\mathcal{R}$ denotes the Radon transform as defined in (A.9). We can therefore recover $\hat{p}_0$ with an inverse Radon transform:

$$
\hat{p}_0 = 2\mathcal{R}^{-1}[\hat{m}_3], \quad \hat{m}_3(r, \theta) = \begin{cases} 
m_3(\theta; \langle \zeta(\theta), \theta \rangle - r) & \text{if } r < \langle \zeta(\theta), \theta \rangle, \\
0 & \text{if } r \geq \langle \zeta(\theta), \theta \rangle.
\end{cases}
$$

Equation (4.11) reveals an interesting property of integrating area detectors: for an arbitrary strictly convex measurement geometry $\Omega$, exact reconstruction formulas exist. This is a property that is not known for conventional and other photoacoustic sectional imaging technologies.

### 4.4. Measurements with horizontal line detectors

For every $\theta \in S^1$, we define the function

$$
\hat{p}_0(r, z; t) = \int_{T(r, \theta)} p(\xi, z; t) \, ds(\xi),
$$

where $T(r, \theta)$ is defined as in (3.7). Then, using that the vectors $(\theta, 0)$, $(\theta^\perp, 0)$ and $(0, 0, 1)$ are an orthonormal basis of $\mathbb{R}^3$ and that the Laplacian is rotationally invariant, the initial value problem (3.2) implies that $\hat{p}_0$ solves for all $r, z \in \mathbb{R}$ and $t > 0$ the two-dimensional wave equation

$$
\partial_t \hat{p}_0(r, z; t) = \int_{-\infty}^{\infty} \Delta_x p(\xi(\theta) + r\theta + u\theta^\perp, z; t) \, du
\quad = \partial_r \hat{p}_0(r, z; t) + \partial_z \hat{p}_0(r, z; t)
$$

with the initial conditions

$$
\partial_t \hat{p}_0(r, z; 0) = 0,
\hat{p}_0(r, z; 0) = P_0(r)\delta(z), \quad P_0(r) = \int_{T(r, \theta)} \hat{p}_0(\xi) \, ds(\xi),
$$

for every $r, z \in \mathbb{R}$.

From formula (A.6), we see that the solution of this initial value problem can be written as

$$
\hat{p}_0(r, z; t) = \frac{1}{2\pi} \partial_r \left( \int_{\mathbb{R}^2 \setminus \{0\}} \frac{P_0(r + \rho)\delta(z + \zeta)}{\sqrt{t^2 - \rho^2 - \zeta^2}} \, ds(\rho, \zeta) \right)
= \frac{1}{2\pi} \partial_r \left( \int_{-t}^{t} \delta(z + \zeta) \int_{-\sqrt{t^2 - z^2}}^{\sqrt{t^2 - z^2}} \frac{P_0(r + \rho)}{\sqrt{t^2 - \rho^2 - \zeta^2}} \, d\rho \, d\zeta \right)
$$

for all $r, z \in \mathbb{R}$ and $t > 0$. Integrating out the $\delta$-function, we find for every $z \in [-t, t]$ that

$$
\hat{p}_0(r, z; t) = \frac{1}{2\pi} \partial_r \left( \int_{-\sqrt{t^2 - z^2}}^{\sqrt{t^2 - z^2}} \frac{P_0(r + \rho)}{\sqrt{t^2 - z^2 - \rho^2}} \, d\rho \right).
$$

Since $\hat{p}_0$ is related to the measurement $m_4$, given by (3.6), via $m_4(\theta; t) = \hat{p}_0(0, 0; t)$, and since $P_0(r) = 0$ for $r > 0$ by the assumption that $\hat{p}_0$ has support inside $\Omega$, we find with formula (A.1) for the Abel transform in reciprocal coordinates that

$$
m_4(\theta; t) = \frac{1}{2\pi} \partial_r \left( \int_{0}^{t} \frac{P_0(-\rho)}{\sqrt{t^2 - \rho^2}} \, d\rho \right) = \frac{1}{4\pi} \partial_r \left( \frac{1}{t} A[\psi_0] \left( \frac{1}{t} \right) \right),
$$
where \( \psi_{\theta}(\rho) = \rho^2 P_{\theta}(-\rho) \). Switching to the reciprocal coordinate \( s = \frac{1}{t} \) and using identity (A.3), we see that this is of the form

\[
\frac{2}{s^2} m_0(\theta; \frac{1}{t}) = -\frac{1}{2\pi} \partial_s(s A[\psi_{\theta}](s)) = A^{-1}[\tilde{\psi}_{\theta}](s)
\]

with \( \tilde{\psi}_{\theta}(\rho) = \frac{1}{\rho} \psi_{\theta}(\rho) = P_{\theta}(-\rho) \). Thus, we can directly solve the equation for \( P_{\theta} \) and find

\[
P_{\theta}(-\rho) = 2 A[\tilde{m}_0](\frac{1}{\rho}) = \rho^2 m_0(\theta; t).
\]

(4.12)

Since we have by definition

\[
P_{\theta}(r) = R[\hat{p}_0](r + \langle \zeta(\theta), \theta \rangle, \theta),
\]

we finally obtain (remembering that \( P_{\theta}(r) = 0 \) for \( r \geq 0 \))

\[
\hat{p}_0 = 2 R^{-1}[\tilde{P}], \quad \tilde{P}(r, \theta) = \begin{cases} A[\tilde{m}_0]\left(\frac{1}{\langle \zeta(\theta), \theta \rangle - r}\right) & \text{if } r < \langle \zeta(\theta), \theta \rangle, \\ 0 & \text{if } r \geq \langle \zeta(\theta), \theta \rangle. \end{cases}
\]

(4.13)

So, the reconstruction of \( \hat{p}_0 \) can be accomplished by an Abel transform of the rescaled measurements \( \tilde{m}_0 \), defined in (4.12), followed by an inverse Radon transform. Again, this reconstruction formula is valid for an arbitrary strictly convex measurement geometry \( \Omega \).

5. Conclusion

In this paper, we have surveyed exact reconstruction formulas for photoacoustic sectional imaging. All formulas are mathematically, analytically exact. Comparing point and integrating line detectors, it is quite surprising that integrating area detectors allow analytical reconstructions for all strictly convex domains. This property has not been observed for point detectors.

Appendix

A.1. Abel transform

The Abel transform \( A[\psi] \) of a smooth function \( \psi : \mathbb{R}_+ \rightarrow \mathbb{R} \), which decays sufficiently fast to zero at \( \infty \), is defined by

\[
A[\psi](y) = \int_{-\infty}^{\infty} \psi(\sqrt{x^2 + y^2}) \, dx = 2 \int_{y}^{\infty} \frac{r \psi(r) \, dr}{\sqrt{r^2 - y^2}}, \quad y \geq 0.
\]

We rewrite the Abel transform in reciprocal coordinates so that it better fits in our context. Substituting \( y = \frac{1}{t} \) and \( r = \frac{1}{s} \), we find that

\[
A[\psi]\left(\frac{1}{t}\right) = 2 \int_{t}^{\infty} \frac{r \psi(r) \, dr}{\sqrt{r^2 - t^2}} = 2 \int_{0}^{t} \frac{s \psi(\frac{1}{s}) \, ds}{\sqrt{s^2 - \frac{1}{t^2}}},
\]

(A.1)
To invert the Abel transform, we remark that we have for all \( v \geq 0 \)
\[
\int_{-\infty}^{\infty} \frac{(A[\psi])'}{\sqrt{u^2 + v^2}} \, du = \int_{-\infty}^{\infty} \frac{\psi' \sqrt{x^2 + u^2 + v^2}}{\sqrt{x^2 + u^2 + v^2}} \, du \, dx \\
= 2\pi \int \frac{\psi'(\rho)}{\rho} \, d\rho = -2\pi \psi(v),
\]
where we substituted \( x = \sqrt{\rho^2 - v^2} \cos(\phi) \) and \( u = \sqrt{\rho^2 - v^2} \sin(\phi) \). Therefore, the inverse Abel transform \( A^{-1}[\psi] \) of a function \( \psi : \mathbb{R}_+ \rightarrow \mathbb{R} \) can be written as
\[
A^{-1}[\psi](y) = -\frac{1}{2\pi y} (A[\psi])'(y). \tag{A.2}
\]
Using the identity
\[
(A[r^2 \psi])'(y) = \partial_y \left( \int_{-\infty}^{\infty} (x^2 + y^2) \psi(\sqrt{x^2 + y^2}) \, dx \right) \\
= \partial_y (y^2 A[\psi](y)) + \int_{-\infty}^{\infty} \frac{x^2 y}{\sqrt{x^2 + y^2}} \psi'(\sqrt{x^2 + y^2}) \, dx \\
= \partial_y (y^2 A[\psi](y)) - y \int_{-\infty}^{\infty} \psi(\sqrt{x^2 + y^2}) \, dx = y \partial_y (y A[\psi](y))
\]
and using (A.2), we can also write the inverse Abel transform in the form
\[
A^{-1}[r^2 \psi](y) = -\frac{1}{2\pi} \partial_y (y A[\psi](y)). \tag{A.3}
\]

### A.2. Circular and spherical means

Let \( x \in \mathbb{R}^n \) and \( r > 0 \). The spherical mean operator in \( \mathbb{R}^n \) of an integrable function \( f : \mathbb{R}^n \rightarrow \mathbb{R} \) is defined by
\[
\mathcal{M}_n[f](x; r) = \frac{1}{|S^{n-1}|} \int_{S^{n-1}} f(x + r\theta) \, d\sigma(\theta), \tag{A.4}
\]
where \( |S^{n-1}| \) denotes the area of the unit sphere \( S^{n-1} \) in \( \mathbb{R}^n \).

The spherical mean value operator is closely related to the solution of the \( n \)-dimensional wave equation
\[
\partial_t p(x; t) = \Delta_x p(x; t), \\
\partial_t p(x; 0) = 0, \\
p(x; 0) = f(x)
\]
for all \( x \in \mathbb{R}^n \) and \( t > 0 \). More precisely, the solution \( p \) can be expressed in terms of the spherical mean operator of \( f \) by (see, e.g., [5])
\[
p(x; t) = \frac{1}{(n-2)!} \partial_t^{n-1} \left( \int_0^t \left( \int_0^r (t^2 - r^2)^{(n-3)/2} \mathcal{M}_n[f](x; r) \, dr \right) \, dt \right)
\]
for all \( x \in \mathbb{R}^n \) and \( t > 0 \). In particular, we have the following.

- For \( n = 2 \) that the solution \( p \) of the two-dimensional wave equation can be calculated from the spherical means via the Abel transform (A.1):
\[
p(x; t) = \partial_t \left( \int_0^t \frac{r \mathcal{M}_2[f](x; r)}{\sqrt{t^2 - r^2}} \, dr \right) = \partial_t \left( \frac{1}{2\pi} A[f](1) \left( \frac{1}{2} \right) \right), \tag{A.5}
\]
where \( \tilde{f}_n(t) := r^3 \mathcal{M}_2[f](x, r) \), leading also to the formula
\[
p(x; t) = \frac{1}{2\pi} \partial_t \left( \int_{B(t)} \frac{f(x + y)}{\sqrt{t^2 - |y|^2}} \text{d}x(y) \right)
\] (A.6)
for all \( x \in \mathbb{R}^2, t > 0 \), where \( B_t^n(0) \subset \mathbb{R}^2 \) denotes the two-dimensional ball with radius \( t \) and center \( 0 \).

- For \( n = 3 \), we obtain that the solution \( p \) of the three-dimensional wave equation and \( \mathcal{M}_3[f] \) are related by
\[
p(x; t) = \partial_t (t \mathcal{M}_3[f](x; t)) = \partial_t \left( \frac{1}{4\pi t} \int_{B(t^n(0))} f(x + y) \text{d}x(y) \right)
\] (A.7)
for all \( x \in \mathbb{R}^3, t > 0 \), where \( \partial B_t^n(0) \) denotes the boundary of the three-dimensional ball \( B_t^n(0) \subset \mathbb{R}^3 \) with radius \( t \) and center \( 0 \).

We remark that we can solve equations (A.5) and (A.7) for the spherical mean operator of \( f \). We obtain for \( n = 2 \) with \( s = \frac{1}{2} \) that
\[
\frac{1}{\pi^s} p \left( x; \frac{1}{s} \right) = -\frac{1}{2\pi} \partial_s (s \mathcal{A}[\tilde{f}_n](s)),
\]
which gives us with representation (A.3) of the inverse Abel transform that
\[
\mathcal{M}_2[f](x; r) = \frac{1}{\pi r} \mathcal{A}[\tilde{p}_n] \left( \frac{1}{r} \right) = \frac{2}{\pi} \int_0^r \frac{p(x; t)}{\sqrt{t^2 - r^2}} \text{d}t, \quad x \in \mathbb{R}^2, r > 0, \quad (A.8)
\]
where \( \tilde{p}_n(\frac{1}{r}) = \sqrt{r} p(x; t) \); and for \( n = 3 \), we find
\[
\mathcal{M}_3[f](x; r) = \frac{1}{r} \int_0^r p(x; t) \text{d}t, \quad x \in \mathbb{R}^3, r > 0.
\]

A.3. The Radon transform

The Radon transform for a smooth function \( g : \mathbb{R}^2 \rightarrow \mathbb{R} \) with compact support is defined by
\[
\mathcal{R}[g] : \mathbb{R} \times S^1 \rightarrow \mathbb{R}, \quad \mathcal{R}[g](r, \theta) = \int_{-\infty}^{\infty} g(r\theta + u\theta^1) \text{d}u.
\] (A.9)
The Radon transform can be inverted and we have the explicit formula
\[
\mathcal{R}^{-1}[G](\xi) = -\frac{1}{(2\pi)^2} \int_{-\infty}^{\infty} \int_{S^1} \partial_r G(r + \langle \theta, \xi \rangle, \theta) \text{d}\theta \text{d}r
\]
for the inverse Radon transform; see, e.g., [16].

A.4. Mathieu functions

The Mathieu functions are the solutions of the Mathieu equation
\[
u''(s) + (a - 2q \cos(2s)) \nu(s) = 0.
\] (A.10)
However, we are only interested in \( 2\pi \)-periodic solutions. It is known (see, e.g., [1]) that for a fixed value \( q \geq 0 \), there only exists a \( 2\pi \)-periodic solution of the equation (A.10) for a discrete set of values \( a \in \mathbb{R} \). Conventionally, the values \( a \) for which an even \( 2\pi \)-periodic solution exists are labeled in increasing order as \( a_n(q) \) with the Mathieu cosine functions \( s \mapsto \cos_n(s; q) \) as corresponding solutions \( n \in \mathbb{N}_0 \), and the values \( a \) for which we have an odd \( 2\pi \)-periodic solution are (again in increasing order) called \( b_n(q) \) with the Mathieu sine
functions $s \mapsto s_n(s, q)$ as corresponding solutions $n \in \mathbb{N}$. The normalization of the solutions $c_n$ and $s_n$ is chosen to be
\[
\int_0^{2\pi} |c_n(s', q)|^2 \, ds' = \pi \quad \text{and} \quad \int_0^{2\pi} |s_n(s', q)|^2 \, ds' = \pi.
\]
Thus, since the functions are the eigenfunctions of the symmetric operator $\partial_{ss} + 2q \cos(2s)$, the functions $\frac{1}{\sqrt{2\pi}} c_n(\cdot; q), \frac{1}{\sqrt{2\pi}} s_n(\cdot; q), n \in \mathbb{N}_0$, form for every $q \geq 0$ a complete orthonormal system of $L^2([0, 2\pi])$.
