Carotane sesquiterpenes from *Ferula vesceritensis*: in *silico* analysis as SARS-CoV-2 binding inhibitors†

Tarik A. Mohamed, a Abdelsamed I. Elshamy, b Mahmoud A. A. Ibrahim, c,d Ammar Zellaqui, d Mahmoud F. Moustafa, e Alaa H. M. Abdelrahman, c Shinji Ohta, g Paul W. Pare h and Mohamed-Elamir F. Hegazy*a

Two sesquiterpenes, 8α-anisate-dauc-4-ene-3,9-dione (webiol anisate) (1) and 10α-acetoxy-6α-benzoate-jaeschkeanadiol (2) as well as, ten known analogues (3–10), and two sesquiterpene coumarins (11–12) were isolated from an organic root extract of *Ferula vesceritensis* (Fam. Apiaceae). Chemical structures were elucidated based on IR, 1D- and 2D-NMR and HRMS, spectroscopic analyses. With molecular overlap observed between two protease inhibitors that are being examined as anti-COVID-19 drugs, and sesquiterpenes isolated here, metabolite molecular docking calculations were made using the main protease (M^pro), which is required for viral multiplication as well as RNA-dependent RNA polymerase (RdRp). In *silico* binding-inhibition analysis predicted that select *F. vesceritensis* sesquiterpenes can bind to these enzymes required for viral replication. Structures of the isolated constituents were also consistent with the chemo-systematic grouping of *F. vesceritensis* secondary metabolites with other *Ferula* species.

Introduction

The genus *Ferula*, composed of approximately 180 species, is the third-largest genus in the Apiaceae family. Over 130 species are distributed throughout the Mediterranean and Central Asia region. Many *Ferula* species are used as traditional medicines for treatments such as impotency and frigidity, skin infections, dysentery, neurological disorders (trianquilizer, anti-hysteric), rheumatism, headache, digestive disorders, dizziness and arthritis. Resins of *Ferula* are used as a febrifuge as well as a carminative agent for stomach disorders. Some *Ferula* species exhibit anticancer, anthelmintic, antimicrobial, antifungal, anticonvulsant, antioxidant, antiproliferative, anti-hypertensive, hepatoprotective and antibiotic-odulation agents. Previous phytochemical studies of *Ferula* species revealed that the main constituents are sesquiterpenes.

*Ferula vesceritensis* (Batt.), also known as *F. tingitana* L. var, is endemic to Algeria and Libya, where it is used as traditional medicine for the treatment of inflammatory, cancer, fever, headaches and throat infections; livestock are observed to avoid grazing on the foliage. Previous *F. vesceritensis* phytochemical studies report the accumulation of sesquiterpenes and sesquiterpene coumarins. With the recent COVID-19 pandemic, the question arises as to whether secondary metabolites from *F. vesceritensis* can serve as inhibitors of enzymes that participate in viral replication.

From the outset, COVID-19 was identified as a new beta coronavirus, initially referred to as SARS-CoV-2 and later named coronavirus disease-2019 (COVID-19) by the World Health Organization. Infections are rapidly spread by respiratory droplets with a high mortality rate in select countries; the pandemic is a significant challenge to public health. With currently no specific antiviral drugs or vaccines developed to treat COVID-19, the virus is more deadly than the SARS, H1N1, MERS, and Ebola epidemics combined with more than 200 000 lives lost to the disease in the first half of 2020. Very recently, the U.S. Food and Drug Administration (FDA) has issued an emergency use authorization of remdesivir for treatment of suspected or laboratory-confirmed COVID-19 cases.
In seeking chemical inhibitors to block COVID-19 replication, the molecular docking technique was utilized to predict binding affinities for compounds isolated from *F. vesceritensis* against SARS-CoV-2 main protease (M\(^\text{PPi}\)) and RNA-dependent RNA polymerase (RdRp), two essential enzymatic components required for viral replication. Compounds included two new sesquiterpenes (1,2) in addition to ten previously reported compounds (3–12) (Fig. 1). Chemo-systematic significance of metabolites from *F. vesceritensis* was also compared with other members of the *Ferula* genus.

### Results and discussion

Extensive fractionation and purification of the organic extract of *F. vesceritensis* afforded two new sesquiterpene, 8\(^\beta\)-anisate-dauc-4-ene-3,9-dione (webdiol anisate) (1) and 10\(^\beta\)-acetoxy-6\(^\alpha\)-benzoate-jaeschkeanadiol (2) as well as ten previously reported compounds, 10\(^\alpha\)-acetoxy-6\(^\alpha\)-anisate-jaeschkeanadiol (3), 18 2\(^\alpha\)-acetoxy-10\(^\beta\)-hydroxy-6\(^\alpha\)-anisate-jaeschkeanadiol (4), 18 2-oxofer-utidin (5), 19 2\(^\alpha\)-acetoxy-6\(^\alpha\)-p-methoxybenzoyl-10\(^\alpha\)-acetoxy-jaeschkeanadiol (6), 18 2\(^\alpha\)-acetoxy-6\(^\alpha\)-p-methoxybenzoyl-10\(^\beta\)-acetoxy-jaeschkeanadiol (7), 18 2-acetoxy-6\(^\alpha\)-p-methoxybenzoyl-jaeschkeanadiol (8), 20 2\(^\alpha\)-hydroxy-6\(^\alpha\)-p-methoxybenzoyl-10\(^\beta\)-acetoxy-jaeschkeanadiol (9), 21 epoxyvescertenol (10), 15 colado-nin (11), 22 feselol (12). 16,22 Structures for the known metabolites were elucidated by comparison of collected spectroscopic data (1D- and 2D-NMR as well as MS data) with literature reports.

Compound 1 was obtained as a reddish amorphous powder with an optical rotation of \([\alpha]_D^{25} +56.9\) in MeOH. TOF-ESI-MS analysis showed molecular ion peak at m/z 407.1827 [M + Na \(^+\)] \(^{\text{[calculated for C}_{24}\text{H}_{32}\text{O}_{5}]}\), 407.1834) indicating a molecular formula of \(\text{C}_{24}\text{H}_{32}\text{O}_{5}\). The \(^{13}\text{C}\) NMR spectrum displayed 23 carbon signals that categorized to 9 quaternary carbons (comprising two keto groups at \(\delta_C\) 205.8, 206.4), 5 methines, 5 methyls (including one methyl of methoxy). From all characterized carbons, para-anisate moiety (\(\delta_C\) 166.3, 121.9, 132.2, 114.3 and 164.3), were clearly assigned. \(^1\)H NMR data revealed the presence of an isopropyl moiety signals at \(\delta_H\) 1.20 (3H, d, \(J = 7.0\) Hz), 1.22 (3H, d, \(J = 7.0\) Hz) and 2.65 (1H, m), 2.65 (1H, m). In addition to methyl groups at \(\delta_H\) 1.04 (3H, s) and 1.69 (3H, s), an anisate moiety with characteristic aromatic protons at \(\delta_H\) 7.04 (2H, d, \(J = 8.9\) Hz) and methoxy protons at \(\delta_H\) 3.72 [s] were observed. These structural elements suggested a carotane skeleton corresponding to a bicyclic structure with a condensed seven and five membered ring system, as previously isolated from several *Ferula* species. 15,16,19,24,25

\(^{11}\)H COSY indicated a blocked correlation between methine proton at \(\delta_H\) 2.65 (m) and two methyl signals at \(\delta_H\) 1.20 (3H, d, \(J = 7.0\) Hz), \(\delta_H\) 1.22 (3H, d, \(J = 7.0\) Hz), indicating that the isopropyl group was located on quaternary olefinic carbon \(\delta_C\) 143.9. Additionally, a characteristic methyl signal at \(\delta_H\) 1.04 (s) for H-15 showed an HMBC correlation with olefinic quaternary carbon at \(\delta_C\) 175.2 as well as methine proton at \(\delta_H\) 2.65 (m). Accordingly, isopropyl signals at \(\delta_H\) 1.22d (\(J = 7.0\) MHz), 1.22d (\(J = 7.0\) MHz) and 2.65 m were assigned H-12, H-13, and H-11, respectively. The quaternary olefinic carbons at \(\delta_C\) 143.9 and 175.2 were assigned to C-4 and C-5, respectively. The methine proton, H-11, showed HMBC correlations with olefinic quaternary carbon at \(\delta_C\) 143.9 (C-4), 175.2 (C-5), a keto group at \(\delta_C\) 206.4 was assigned to C-3. H-15 showed HMBC correlations with quaternary aliphatic carbon at \(\delta_C\) 41.1 and two aliphatic methylene carbons at \(\delta_C\) 48.9, 43.0 assigned to C-1, C-2, and C-10 respectively that associated with the cyclopentane ring. The remaining proton signals for two methylene groups with a vicinal relationship was deduced via COSY and HSQC analyses [\(\delta_H\) 2.74 (1H, m), 2.83 (1H, m) and \(\delta_C\) 21.1] and [\(\delta_H\) 1.53 (1H, m), 2.65 (1H, m) and \(\delta_C\) 40.7] and HMBC analysis confirm localization to C-6 and C-7. Finally, the location of the anisate moiety was deduced by the correlation between the proton at \(\delta_H\) 1.69 s (H-14) and C-7 (\(\delta_C\) 40.7), keto group at \(\delta_C\) 205.8 and a quaternary carbon with an oxygen function (\(\delta_C\) 86.0) indicating that the anisate group and CH\(^3\)-14 attached to a quaternary carbon with an oxygen function \(\delta_C\) 86.0 (C-8). These correlations also confirmed the presence of the ketone at C-9. The position of the anisate at C-8 was as well deduced from the comparison of the NMR spectra with those the anisate derivative of webdiol that characterized by presence of a cycloheptane ring at C-8. 15,19,25

The relative stereochemistry was deduced through coupling constants and NOESY analysis. NOESY correlations of H-15 with H-2\(\beta\) and H-10\(\beta\), and H-10\(\beta\) with H-14 showed that H-15, H-14 are in a \(\beta\) orientation. Thus, the structure of 1 was determined as 8\(^\beta\)-anisate-dauc-4-ene-3,9-dione.

Compound 2 was obtained as a reddish amorphous powder with an optical rotation of \([\alpha]_D^{25} +20\) in MeOH. TOF-ESI-MS analysis showed a molecular ion peak at m/z 400.2249 [M\(^+\)] \(^{\text{[calculated for C}_{23}\text{H}_{28}\text{NaO}_{5}]}\), 400.2222) indicating a molecular formula of \(\text{C}_{23}\text{H}_{28}\text{NaO}_{5}\). \(^1\)H NMR data revealed the presence of an isopropyl moiety with signals at \(\delta_H\) 0.83 (3H, d, \(J = 6.6\) Hz), 0.96 (3H, d, \(J = 6.6\) Hz) and 1.95 (1H, m). In addition to methyl groups at \(\delta_H\) 1.18 (3H, s), 1.82 (3H, s) and 2.07 (3H, s); a benzoate moiety with

![Fig. 1 Isolated compounds from *Ferula vesceritensis*.](image-url)
characteristic aromatic protons at $\delta_H$ 8.00 (2H, d, $J = 7.2$ Hz), 7.46 (2H, t, $J = 7.8$ Hz) and 7.58 (1H, t, $J = 7.8$ Hz) was observed. The $^{13}$C NMR spectrum displayed 24 carbon signals (Table 1), which were further differentiated by DEPT to 5 methyls (1 acetate group), 3 methylenes, 10 methines (two oxygenated, 6 olefinic) and 5 quaternary carbons (1 oxygenated, 2 keto, 2 olefinic). Spectroscopic data were similar to 3 except the appearance of an additional olefinic proton at $\delta_H$ 7.58 (1H, t, $J = 7.8$) and the disappearance of methoxy protons. This methoxy substitution was confirmed by $^{13}$C-NMR analysis. 2D NMR (COSY, HMOC and HMBC) analyses (Fig. 2) and comparisons with published analogues indicated a 7/5 bicyclic cadinane-type sesquiterpene previously isolated from different Ferula species.\textsuperscript{15,16,19,24,25} The two methylene groups with a vicinal attachment to the methine carbon $\delta_C$ 70.4 (C-6) and that the carbons signals at $\delta_C$ 41, 130.2 and 128.8 are assigned to C-7, C-8 and C-9, respectively. These data confirm the presence of an acetate group at C-10. The two methylene groups with a vicinal relationship deduced via COSY and HSQC analysis [$\delta_H$ 1.68 (m), 1.24 (m) and $\delta_C$ 37.5] and [H-3 at $\delta_H$ 1.57 m, 1.93 m and $\delta_C$ 31.2] and a blocked correlation between methine proton at $\delta_H$ 1.95 (m) and two methyl signals at $\delta_H$ 0.83 (3H, d, $J = 6.6$ Hz), $\delta_H$ 0.96 (3H, $J = 6.6$ Hz) were observed. Long-range $^1$H-$^{13}$C correlations associated with two methyl groups ($\delta_H$ 0.83 and 0.96) to the carbon signals at $\delta_C$ 37.3 and 86.5 as well as methylene protons H-2 $\delta_H$ 1.68 (m), 1.24 (m) and H-3 at $\delta_H$ 1.57 m, 1.93 m were also observed. Additionally, a characteristic methyl signal at $\delta_H$ 1.20 s for H-15 showed correlation with the carbon signals at $\delta_C$ 48.2 (C-1), 37.7 (C-2), 57.7 (C-5) and 80.7 (C-10) indicating that the isopropyl group and acetate groups were located on quaternary oxygenated carbon $\delta_C$ 86.5 for C-4 and oxygenated methine carbon at $\delta_C$ 80.7 for C-10 respectively. Finally, the location of the benzoate moiety was deduced by the correlation between the olefinic methyl at $\delta_H$ 1.82 s for H-14 via HMBC correlations with carbons signals at $\delta_C$ 130.2, 128.8 and the carbon of methylene at $\delta_C$ 41.2 as well as H-5 at $\delta_H$ 2.11 d (10.8). In addition, correlations of H-5 with carbon of oxygenated methine at $\delta_C$ 70.4 were observed; these correlations indicate that the benzoate group is attached to the methine carbon $\delta_C$ 70.4 (C-6) and that the carbons signals at $\delta_C$ 41, 130.2 and 128.8 are assigned to C-7, C-8 and C-9, respectively. These data confirm the presence of an acetate group at C-10.

### Table 1 $^1$H (500 MHz) and $^{13}$C (125 MHz) NMR chemical shifts for 1 and 2

|   | $^1$H NMR (C$_5$D$_5$N, $J$ MHz) | $^{13}$C NMR (C$_5$D$_5$N) |   | $^1$H NMR (CDCl$_3$, $J$ MHz) | $^{13}$C NMR (CDCl$_3$) |

| 3’,7’ | 8.24 d (8.9)                | 132.2                    | 21| —                              | 131.5                    |
| 4’,9’ | 7.07 d (8.9)                 | 114.3                    | 22| —                              | 129.6                    |
| 5’ | —                              | 164.3                    | 23| 8.00 d (7.2)                    | 128.6                    |
| OCH$_3$ | 3.72 s                  | 55.4                     | 24| 7.46 t (7.8)                    | 133.3                    |
| C==O, OAc | —                                | —                        | 25| 7.58 t (7.8)                    | —                        |
| CH$_3$, OAc | —                                | —                        | 26| —                              | 170.8                    |
|     | 2.07 s                         | 21.2                     |   |                                |                          |
The relative stereochemistry was deduced via a coupling constant, a td for proton at $\delta_H \ 5.30$ (1H, $J = 10.8, 3.0, H-6$) is characteristic for the C-6$^\beta$ geminal proton of trans-fused daucane skeletons.$^{18}$ A small coupling between protons at $\delta_H \ 5.25$ (1H, s, H-9) and 5.22 (1H, s, H-10) was only possible when the proton at C-10 in $z$ orientation; therefore acylated group at C-10 in the $\beta$ orientation.$^{20}$ The structure of 2 was therefore identified as 10$\beta$-acetoxyl-6$\alpha$-benzoate-jaeschkeanadiol.

**Molecular docking**

Utilizing AutoDock molecular docking software, binding affinities were predicted for isolated compounds 1–12 with SARS-CoV-2 M$^{pro}$ and RdRp to inhibit SARS-CoV-2 replication. The predicted binding affinities are listed in Table 2 and compared to two human immunodeficiency virus (HIV) protease inhibitors that have recently been subjected to clinical investigations as promising anti-COVID-19 drugs:$^{26}$ darunavir (DrugBank code: DB01264) and lopinavir (DrugBank code: DB01601). Two-dimensional representations for binding modes of 1–12 as well as darunavir and lopinavir inside the active sites of SARS-CoV-2 M$^{pro}$ and RdRp are depicted in Fig. S2 and S3,$^\dagger$ respectively. The assayed natural products exhibited intermediate binding affinities towards SARS-CoV-2 M$^{pro}$, and RdRp with docking scores ranged from −9.9 to −6.7 and from −7.6 to −6.4 kcal mol$^{-1}$, respectively (Table 2). The observed high affinities are attributed to multiple hydrogen bonds, van der Waals and hydrophobic interactions between the natural products and proximal amino acids in the enzyme active site for M$^{pro}$ and RdRp. Compound 1 demonstrated the highest binding affinities of −9.9 and −7.6 kcal mol$^{-1}$, forming three hydrogen bonds with HIS163 (1.81 Å) and GLU166 (2.10, 2.08 Å), and six hydrogen bonds with TYR619 (1.99 Å), LYS621 (1.84, 2.05, 2.39 Å), CYS622 (1.78 Å) and LYS798 (2.21 Å) inside the active sites of M$^{pro}$ and RdRp, respectively (Fig. 3 and 4).

**Table 2** Calculated docking scores (in kcal mol$^{-1}$) and binding features for the identified compounds 1–12 with SARS-CoV-2 main protease (M$^{pro}$) and RNA-dependent RNA polymerase (RdRp)

| Compound | Docking score (kcal mol$^{-1}$) | Binding features | Docking score (kcal mol$^{-1}$) | Binding features |
|----------|---------------------------------|-----------------|---------------------------------|-----------------|
|          |                                 | (hydrogen bond length in Å) |                                 | (hydrogen bond length in Å) |
| 1        | −9.9                            | HIS163 (1.81 Å), GLU166 (2.10, 2.08 Å) | −7.7                           | TYR619 (1.99 Å), LYS621 (1.84, 2.05, 2.39 Å), CYS622 (1.78 Å), LYS798 (2.21 Å) |
| 2        | −8.8                            | GLY143 (1.95 Å), GLU166 (2.06 Å) | −7.5                           | ASP618 (2.23 Å), ASP623 (2.86 Å), CYS622 (2.02 Å), TRP800 (1.96 Å) |
| 3        | −6.6                            | —                | −6.9                           | ASP618 (2.26 Å), LYS621 (2.25, 2.52 Å), TRP800 (2.14 Å) |
| 4        | −7.4                            | GLU166 (2.45 Å) | −6.2                           | ASP618 (2.22 Å), LYS621 (2.20 Å), TRP800 (2.07 Å) |

Compared to 1, the docking scores of lopinavir are similar to binding affinities of $-9.8$ and $-7.5$ kcal mol$^{-1}$ towards M$^\text{pro}$ and RdRp, respectively. In contrast, darunavir showed lower docking scores of $-8.2$ and $-4.4$ kcal mol$^{-1}$ with M$^\text{pro}$ and RdRp, respectively. Together these results provide quantitative data of the binding affinities of 1 as promising SARS-CoV-2 M$^\text{pro}$ and RdRp inhibitor.

**Molecular target prediction and network analysis**

Using Swiss Target Prediction software, gene overlap between predicted responses activated by 1 and protein targets associated with severe acute respiratory syndrome diseases showed EGFR, MAPK14, and CTSL, as illustrated in the Venn diagram comparison (Fig. 5). Epidermal growth factor receptor (EGFR) inhibition may prevent an extreme fibrotic response to SARS-CoV and other respiratory viral infections and modulate the wound healing response to SARS-CoV.$^{27}$ MAPK14 inhibition is predicted to block the ACE2 signaling pathway, and in turn, reduce cell internalization of SARS-CoV-2.

Angiotensin-converting enzyme 2 (ACE2) is a host protein and the receptor for SARS-CoV-2 entry.$^{28}$ The cysteine protease cathepsin L (CTSL) is implicated in several types of pathology, and its inhibition plays a role in controlling inflammation, counterproductive immune responses. Besides, CTSL is an alternate molecular marker for drug design against SARS.$^{29}$ The development of protease inhibitors able to inhibit CTSL, CTSB, and related proteases would be an excellent starting point for the development of broad-spectrum antiviral therapies. Targets genes activated by compound 1 were also analyzed via a STRING-PPI network and visualized by Cytoscape 3.8.0. EGFR
and MAPK14 were observed among the top 10 scored genes for 1 (Table S1†).

Chemosystematic significance

From *F. vesceritensis* collected from the Algerian Sahara, our team and others isolated and identified several compounds mainly sesquiterpenes such as feselol, 13-hydroxyseselol, 3-angeloycoladonin, ferulinsac acid, (−)-samarcandone, 1-methoxy-β-L-glucopyranoside, lapiferin, 10-hydroxylancasterol-6-anisate, 2,10-diacytley-8-hydroxyferrutil-6-anisate, 10-hydroxylancasterol-6-benzoate, vesciterenone and epoxy-vesciterenol, farnesiferol A, 2-acetyl-jaechkeanadiol-6-anisate, lasidiol-10-anisate, 10-oxyjaechkeanadiol-6-anisate, lapidol, coladin, coladonin, lanceridiol p-hydroxybenzoate and jaeschkeanin.¹⁻⁵⁻¹⁰ In the present study, 12 secondary metabolites including two new carotene sesquiterpenes 1 and 2 were identified.

The chemotaxonomic significance of *F. vesceritensis* was established depending upon the comparison of the described chemical compounds including our isolates and the isolated compounds from other *Ferula* ecospecies around the world. Our results as well as previous studies¹²⁻¹⁶⁻¹⁸ have found that isolated sesquiterpenes comprise mainly of daucane and/or carotene type sesquiterpenes in addition to some sesquiterpenes coumarins. This first overview showed complete agreement between the isolates of our plant and all described metabolites from other *Ferula* species.¹⁴ In addition to daucane-type sesquiterpenes, sesquiterpene lactone and glycosides are commonly described sesquiterpenes from the genus such as *F. hermo- nis*,⁴⁻²³⁻³¹ *F. communis* subsp. *communis*,⁴⁻²⁵ *F. varia*,²⁵ *F. Diversivittata*,¹⁴ *F. Sinaica*,²⁴ and *F. jaeschkeana*.⁴⁻¹⁴ A genetic correlation between *F. vesceritensis* and other *Ferula* species were deduced via an overlap of sesquiterpenes and sesquiterpenes esters and more specifically with the diversity of carotene type sesquiterpenes.

*F. vesceritensis* also exhibited a presence of sesquiterpene coumarins. Survey of the plants belonging to *Ferula* genus, sesquiterpene coumarins were found as one of the main characteristic metabolites for this genus such as *F. teterrima*, *F. sinkiangensis*,¹⁴ *F. narthex*,¹⁴ *F. assa-foetida*,²⁶ *F. tunetana*,²⁷ *F. fukanensis*,¹⁸ *F. sinaica*,²¹ *F. assa-foetida*¹⁴ and others.³⁹ From these reports *F. vesceritensis* was deduced to be closely related with other *Ferula* species based on sesquiterpene type.

Eudesmanolide sesquiterpenes, their esters, and glycosides are present in some *Ferula* species. For examples, *F. sinaica*,²⁴ and *F. varia*²¹⁻⁴⁰ biosynthesize eudesmanolide sesquiterpenes. Also, *F. ferulioides* is observed to synthesize a diversity of carotene and/or daucane sesquiterpenes esters and sesquiterpene coumarins. Also, *F. sinaica*, and *F. varia* were characterized by special types of sesquiterpenes, eudesmanolides while *F. ferulioides* was characterized with respect to phenones sesquiterpenes and sesquiterpene coumarins with special skeletons.

Experimental

General experimental procedures

Optical rotations were recorded on a JASCO P-2300 polarimeter (Tokyo, Japan). NMR spectra were measured on a Bruker 500 NMR spectrometer (USA)-500 spectrometer (500 MHz for ¹H and 125 MHz for ¹³C, respectively). All chemical shifts (δ) are given in ppm units with reference to TMS as an internal standard, and coupling constants (J) are reported in Hz. HRMS experiments were performed on Fourier transform ion cyclotron mass spectrometer. High-performance liquid chromatography (HPLC) was performed on an Agilent pump equipped with an Agilent-G1314 variable wavelength UV detector at 254 nm and a semi-preparatory reverse-phase column (Econosphere™, RP-C₁₈, 5 μm, 250 × 4.6 mm, Alltech, Deerfield, IL, USA). Silica gel 60 (230–400 mesh) was used for column chromatography. Pre-coated silica gel plates (Kieselgel 60 F₂₅₄, 0.25 mm) were used for TLC analyses. Spots were visualized by heating after spraying with 10% H₂SO₄.

Plant material

Roots of *F. vesceritensis* were collected during the flowering stage in March 2017 near Biskra, approximately 300 miles southeast of Algiers, Algeria by Prof. Dr Amar Zellagui, Department of Chemistry, Constantine University, where a voucher specimen has been deposited (AM#112).

Extraction and separation

Root of *F. vesceritensis* (1 kg) was crushed and extracted with CH₃Cl₂-MeOH (1 : 1) at room temperature. The extract was concentrated *in vacuo* to obtain a residue (30 g). The residue was fractionated by silica gel CC (6 × 120 cm) eluted with n-hexane (3 L), followed by a gradient of n-hexane–CH₂Cl₂ up to 100% CH₂Cl₂ and CH₂Cl₂–MeOH up to 15% MeOH (2 L of each solvent mixture).

Root of *F. vesceritensis* (1 kg) (3 g) was subjected to a second silica gel column (3 × 120 cm) eluted with n-hexane : CH₂Cl₂ (6 : 1) generating two subfractions. Subfraction 1A (0.8 g) was further purified by HPLC eluted with MeOH : H₂O (80 : 20). The flow rate was set to 1.5 mL min⁻¹ and was at 0–70 min to afford 1 (10 mg, purity >98% by HPLC), (eluent hexane/EtOAc 2 : 1, Rf = 0.45) and 2 (15 mg purity >96% by HPLC), (eluent hexane/EtOAc 2 : 1, Rf = 0.40). Subfraction 2A (1 g) was also purified by HPLC eluted with MeOH : H₂O (75 : 25) The flow rate was set at 1.5 mL min⁻¹ was at 0–60 min to afford 3 (25 mg, purity >98% by HPLC), (eluent hexane/EtOAc 1 : 2, Rf = 0.25), 4 (25 mg, purity >97% by HPLC), (eluent n-hexane/ EtOAc 1 : 1, Rf = 0.45) and 10 (35 mg, purity >98% by HPLC), (eluent hexane/EtOAc 1 : 2, Rf = 0.30). An n-hexane CH₂Cl₂
(1 : 3) fraction (3.3 g) was subjected to a silica gel fractionation (3 × 120 cm) eluted with n-hexane–CH2Cl2–MeOH to give two subfractions. Subfraction 1B (1.2 g) was further purified by HPLC eluted with MeOH : H2O (70 : 30). The flow rate was set at 2.0 mL min⁻¹ was at 0–60 min to afford 5 (25 mg, purity >98% by HPLC), eluted with n-hexane/EtOAc 1 : 2, Rf = 0.25; 6 (15 mg, purity >98% by HPLC), eluted with n-hexane/EtOAc 1 : 2, Rf = 0.33); 7 (20 mg, purity >98% by HPLC), eluted with n-hexane/EtOAc 1 : 2, Rf = 0.30 and 8 (10 mg, purity >98% by HPLC), eluted with n-hexane/EtOAc 1 : 2, Rf = 0.35); subfraction 2B (1.5 g) was also purified by HPLC eluted with MeOH : H2O (70 : 30). The flow rate was set at 1.5 mL min⁻¹ was at 0–60 min to afford 9 (12 mg, purity >98% by HPLC), (eluent n-hexane/EtOAc 1 : 1, Rf = 0.40). The 100% CH3Cl2 fraction was subjected to HPLC eluted with MeOH : H2O (65 : 35). The flow rate was set at 2.0 mL min⁻¹ was at 0–60 min to afford 10 (17 mg, purity >96% by HPLC), (eluent n-hexane/EtOAc 1 : 2, Rf = 0.45) and 12 (17 mg, purity >97% by HPLC), (eluent n-hexane/EtOAc 1 : 2, Rf = 0.40).

8z-Anisate-dauc-4-ene-3,9-dione (webiol anisate) (1). A reddish amorphous powder; [α]D +56.9 (c 0.001 MeOH); ¹H and ¹³C NMR data, see Table 1; HRTOF-ESI-MS m/z 407.1793 [M + Na]⁺ (caled for C23H28NaO5, 407.1807).

10β-Acetoxyl-6z-benzoate-jaeschkeanadiol (2). A reddish amorphous powder; [α]D +20 (c 0.001 MeOH); ¹H and ¹³C NMR data, see Table 1; HRTOF-ESI-MS m/z 400.2249 [M⁺]⁺ (caled for C24H32O5, 400.2222).

Molecular docking calculations

Autodock v.4.2 software was used to perform all molecular docking calculations. The crystal structures of SARS-CoV-2 main protease (Mpro; PDB code: 6LU7 [ref. 44]) and RNA-dependent RNA polymerase (RdRp) (PDB code: 6M71 [ref. 45]) were taken as templates. Water molecules, ions, and ligand, if exist, were deleted. H⁺ server was chosen to study the protonation state of RNA polymerase (RdRp; PDB code: 6M71 [ref. 45]) and all missing hydrogen atoms were accordingly added. Default docking parameters were employed, except the number of genetic algorithm (GA) run and the maximum number of energy evaluation (eval). The GA and eval values were set to 250 and 25 000 000, respectively. The docking grid was set to 60 Å × 60 Å × 60 Å with a grid spacing value of 0.375 Å. The grid center was placed at the center of the active site of Mpro and RdRp. Prior to molecular docking, 3D structures of the isolated compounds were minimized using SYBYL software with MMFF94S force field software (SYBYL, 2016). The partial atomic charges for the compounds were calculated using Gasteiger method. The predicted binding poses for each compound were processed by the built-in clustering analysis (1.0 Å RMSD tolerance), and the lowest energy conformation from the largest cluster was selected as representative.

Protein–protein interactions

The online web-based tools of Swiss Target Prediction (http://www.sweisstargetprediction.ch) were applied to predict the biological targets for the most promising isolated compounds as SARS-CoV-2 inhibitors. The Dis Ge NET online database (https://www.disgenet.org) was utilized to collect the available database for SARS diseases. Venn diagram was designed using Interactive Venn online tool. Protein–protein interaction (PPI) network was generated using a functional database of STRING for top predicted targets. Cytoscape 3.8.0 was employed to investigate target-function relation based on the network topological.

Conclusion

Ferula vesceritensis root extract afforded two new sesquiterpenes, 8z-anisate-dauc-4-ene-3,9-dione (webiol anisate) (1) and 10z-acetoxyl-6z-benzoate-jaeschkeanadiol (2) and ten known secondary metabolites. All compounds were in silico tested as anti-COVID-19 drugs using the main protease (Mpro) and RNA-dependent RNA polymerase (RdRp). The binding affinities indicated that 1 was a promising SARS-CoV-2 Mpro and RdRp inhibitor.
