NONEQUILIBRIUM FLUCTUATIONS FOR A TAGGED PARTICLE IN ONE-DIMENSIONAL SUBLINEAR RATE ZERO-RANGE PROCESSES

MILTON JARA, CLAUDIO LANDIM, AND SUNDER SETHURAMAN

Abstract. Nonequilibrium fluctuations of a tagged, or distinguished particle in a class of one dimensional mean-zero zero-range systems with sublinear, increasing rates are derived. In Jara-Landim-Sethuraman (2009), processes with at least linear rates are considered.

A different approach to establish a main “local replacement” limit is required for sublinear rate systems, given that their mixing properties are much different. The method discussed also allows to capture the fluctuations of a “second-class” particle in unit rate, symmetric zero-range models.

1. Introduction and Results

Zero-range processes follow a collection of random walks on a lattice which interact in the following way: Informally, a particle at a location with \( k \) particles displaces by \( j \) with infinitesimal rate \( (g(k)/k)p(j) \) where the process rate \( g : \mathbb{N}_0 \to \mathbb{R}_+ \) is a function on the non-negative integers, and \( p(\cdot) \) is a translation-invariant single particle transition probability. These processes have served as formal models for types of queuing, traffic, fluid, granular flow etc. A review of some of the applications can be found in [2].

Different behaviors may be found by varying the choice of rate \( g \), when say \( p \) is symmetric and nearest-neighbor. For instance, the spectral gap or mixing properties of the system defined on a cube of width \( n \) with \( k \) particles depend strongly on the asymptotic growth of \( g \). For a class of models, when \( g \) is on linear order, the gap is order \( n^{-2} \) and does not depend on \( k \) [10]. However, when \( g \) is the unit rate, \( g(x) = 1 \{ x \geq 1 \} \), the gap is of order \( n^{-2}(1 + \rho)^{-2} \) where \( \rho = k/n \) [12]. Also, when \( g \) is sub-linear, of form \( g(x) = x^\gamma \) for \( 0 < \gamma \leq 1 \), the gap is of order \( n^{-2}(1 + \rho)^{\gamma - 1} \) [13].

We will consider “attractive” models, that is those with increasing rates \( g \), on one dimensional tori \( \mathbb{T}_N = \mathbb{Z}/N\mathbb{Z} \). We will also assume \( g \) is either bounded or sublinear of a certain type. In addition, we suppose the jump probability \( p \) is finite-range and mean-zero. The aim of the article is to understand certain “nonequilibrium” scaling limits of a distinguished, or tagged particle in this setting.

Because of the particle interaction, the tagged particle is not Markovian with respect to its own history. However, one expects that its position to homogenize to a diffusion with parameters given in terms of the “bulk” hydrodynamic density.

S. Sethuraman was partially supported by NSF 0906713 and NSA Q H982301010180.
Although fluctuations of Markov processes are much examined (cf. Komorowski-Landim-Olla [9], and there are many central limit theorems for types of tagged particles when the system is in “equilibrium” (cf. Kipnis-Varadhan [8], Saada [16], Sethuraman [17]), much less is understood when particles both interact nontrivially, and begin in “nonequilibrium”.

In this context, the only previous work treating a general class of interacting particle systems in a systematic way is Jara-Landim-Sethuraman [6] which proves a nonequilibrium functional central limit theorem for a class of zero-range processes whose rates $g$ have at least linear growth, that is $g(k) \geq c_1 k$ for $c_1 > 0$. The proof in [6] relies on an important estimate, a “local” hydrodynamic limit, which however makes strong use of the linear growth of $g$, in particular that the spectral gap on a localized cube does not depend on the number of particles in the cube. Unfortunately, this proof does not carry over to the bounded or sublinear rate case.

A main contribution of this article is to supply a different approach for the main “local replacement” (Theorem 1.6) with respect to a class of increasing, bounded or sublinear rate zero-range models so that the nonequilibrium limit for the tagged particle can be established (Theorem 1.2). As in [6], a consequence of the argument is that the limit of the empirical density in the reference frame of the tagged particle can be identified as the hydrodynamic density in the frame of the limit tagged particle diffusion (Theorem 1.3).

We remark the approach taken here with respect to the “local replacement” is robust enough so that it can apply to determine the nonequilibrium fluctuations of a “second-class” particle, and associated reference frame empirical density, in the symmetric unit rate case, that is when $g(k) = 1\{k \geq 1\}$ (Theorems 1.4, 1.5). This is the first work to address a nonequilibrium central limit theorem for a second-class particle.

Finally, we mention other central limit theorems for a tagged particle which take advantage of special features in types of exclusion and interacting Brownian motion models can be found in Jara and Landim [5], Jara [4], and Grigorescu [3]. Note also “propagation of chaos” results yield homogenization limits for the averaged tagged particle position in simple exclusion, Rezakhanlou [15].

Let now $\xi_t = \{\xi_t(x) : x \in \mathbb{T}_N\}$ be the zero-range process on $\mathbb{T}_N = \mathbb{Z}/N\mathbb{Z}$ with single particle transition probability $p(\cdot)$ and process rate $g: \mathbb{N}_0 \to \mathbb{R}_+$. We will assume that $g(0) = 0$, $g(1) > 0$, and that $g$ is increasing (or “attractive”), $g(k + 1) \geq g(k)$ for $k \geq 1$. In addition, throughout the paper, and in all results, we impose one of the following set of conditions (B) or (SL):

(B) $g$ is bounded: For $k \geq 1$, there are constants $0 < a_0 \leq a_1$ such that $a_0 \leq g(k) \leq a_1$.

Before specifying the class of sublinear rates considered, let $W(l,k)$ be the inverse of the spectral gap of the process defined on the cube $\Lambda_l = \{-l, \ldots, l\}$ with $k$ particles, when the transition probability $p$ is symmetric and nearest-neighbor (cf. Section 2 for more definitions).

(SL1) $g$ is sublinear: $\lim_{k \to \infty} g(k) = \infty$, $g(k)/k: \mathbb{N} \to \mathbb{R}_+$ is decreasing, and $\lim_{k \to \infty} g(k)/k = 0$. In particular, since $g$ is increasing, there exists constants $a_0, a_1 > 0$ such that $a_0 \leq g(k)$ and $g(k)/k \leq a_1$, $k \geq 1$.

(SL2) $g$ is Lipschitz: There is a constant $a_2$ such that $|g(k + 1) - g(k)| \leq a_2$ for $k \geq 0$. 
(SL3) The spectral gap satisfies, for all constants $C$ and $l \geq 1$, that
\[
\lim_{N \to \infty} N^{-1} \max_{1 \leq k \leq C \log N} k^2 W(l, k) = 0. \quad (1.1)
\]

It is proved in Lemma 2.2 that all processes with bounded rates $g$ satisfy (1.1).

In addition, by the spectral gap estimate 13, processes with rates $g(k) = k^\gamma$ for $0 < \gamma \leq 1$ satisfy (1.1). In addition, we will assume that $p$ is finite-range, irreducible, and mean-zero, that is

(MZ) There exists $R > 0$ such that $p(z) = 0$ for $|z| > R$, and $\sum z p(z) = 0$.

We also will take the scaling parameter $N$ larger than the support of $p(\cdot)$.

Denote by $\Omega_N = \mathbb{N}_0^{T_N}$ the state space and by $\xi$ the configurations of $\Omega_N$ so that $\xi(x)$, $x \in T_N$, stands for the number of particles in site $x$ for the configuration $\xi$. The zero-range process is a continuous-time Markov chain generated by
\[
(\mathcal{L}_N f)(\xi) = \sum_{x \in T_N} \sum_z p(z) g(\xi(x)) \left[ f(\xi^{x,x+z}) - f(\xi) \right], \quad (1.2)
\]
where $\xi^{x,y}$ represents the configuration obtained from $\xi$ by displacing a particle from $x$ to $y$:

\[
\xi^{x,y}(z) = \begin{cases} 
\xi(x) - 1 & \text{for } z = x \\
\xi(y) + 1 & \text{for } z = y \\
\xi(z) & \text{for } z \neq x, y.
\end{cases}
\]

The zero-range process $\xi(t)$ has a well known explicit family product invariant measures $\bar{\mu}_\varphi$, $0 \leq \varphi < \lim g(k) =: g(\infty)$, on $\Omega_N$ defined on the nonnegative integers,

\[
\bar{\mu}_\varphi(\xi(x) = k) = \frac{1}{Z_\varphi} \varphi^k g(k)! \text{ for } k \geq 1 \text{ and } \bar{\mu}_\varphi(\xi(x) = 0) = \frac{1}{Z_\varphi}
\]
where $g(k)! = g(1) \cdots g(k)$ and $Z_\varphi$ is the normalization. Denote by $\rho(\varphi)$ the mean of the marginal $\bar{\mu}_\varphi$, $\rho(\varphi) = \sum_k k \bar{\mu}_\varphi(\xi(x) = k)$. Since $g$ is increasing, the radius of convergence of $Z_\varphi$ is $g(\infty)$, and $\lim_{\varphi \uparrow g(\infty)} \rho(\varphi) = \infty$. As $\rho(0) = 0$ and $\rho(\varphi)$ is strictly increasing, for a given $0 \leq \rho < \infty$, there is a unique inverse $\varphi = \varphi(\rho)$. Define then the family in terms of the density $\rho$ as $\mu_\varphi = \bar{\mu}_{\varphi(\rho)}$.

Now consider an initial configuration $\xi$ such that $\xi(0) \geq 1$, and let $\Omega^* \subset \Omega$ be the set of such configurations. Distinguish, or tag one of the particles initially at the origin, and follow its trajectory $X_t$, jointly with the evolution of the process $\xi_t$. It will be convenient for our purposes to consider the process as seen by the tagged particle. This reference process $\eta(t) = \xi_t(x + X_t)$ is also Markovian and has generator in form $L_N = L_N^{env} + L_N^{tp}$, where $L_N^{env}$, $L_N^{tp}$ are defined by
\[
(L_N^{env} f)(\eta) = \sum_{x \in T_N \setminus \{0\}} \sum_z p(z) g(\eta(x)) \left[ f(\eta^{x,x+z}) - f(\eta) \right]
+ \sum_y p(y) g(\eta(0)) \frac{\eta(0) - 1}{\eta(0)} \left[ f(\eta^{0,y}) - f(\eta) \right], \quad (1.3)
\]
\[
(L_N^{tp} f)(\eta) = \sum_z p(z) \frac{g(\eta(0))}{\eta(0)} \left[ f(\theta_z \eta) - f(\eta) \right].
\]
In this formula, the translation $\theta_z$ is defined by

$$
(\theta_z \eta)(x) = \begin{cases} 
\eta(x + z) & \text{for } x \neq 0, -z \\
\eta(z) + 1 & \text{for } x = 0 \\
\eta(0) - 1 & \text{for } x = -z.
\end{cases}
$$

The operator $L^\pi_N$ corresponds to jumps of the tagged particle, while the operator $L^{env}_N$ corresponds to jumps of the other particles, called environment.

A key feature of the tagged motion is that it can be written as a martingale in terms of the reference process:

$$
X_t = \sum_j j N_t(j) = \sum_j j M_t(j) + m \int_0^t \frac{g(\eta_s(0))}{\eta_s(0)} \, ds = \sum j M_t(j),
$$

where $m = \sum j p(j) = 0$ is the mean drift, $N_t(j)$ is the counting process of translations of size $j$ up to time $t$, and $M_t(j) = N_t(j) - p(j) \int_0^t g(\eta_s(0))/\eta_s(0) \, ds$ is its corresponding martingale. In addition, $M_t^2(j) - p(j) \int_0^t g(\eta_s(0))/\eta_s(0) \, ds$ are martingales which are orthogonal as jumps are not simultaneous a.s. Hence, the quadratic variation of $X_t$ is $(X)_t = \sigma^2 \int_0^t g(\eta_s(0))/\eta_s(0) \, ds$ where $\sigma^2 = \sum j^2 p(j)$.

For the reference process $\eta_t$, the “Palm” or origin size biased measures given by $d\nu_t = (g(0)/\rho) d\mu_t$ are invariant (cf. [14], [16]). Note that $\nu_t$ is also a product measure whose marginal at the origin differs from that at other points $x \neq 0$. Here, we take $\mu_0 = \delta_{00}$, the Dirac measure concentrated on the configuration $00$ with exactly one particle at the origin, and note that $\nu_t$ converges to $\delta_{00}$ as $\rho \downarrow 0$.

The families \{\mu_\rho : \rho \geq 0\} and \{\nu_\rho : \rho \geq 0\} are stochastically ordered. Indeed, this follows as the marginals of $\mu_\rho$ and $\nu_\rho$ are stochastically ordered. Also, since we assume that $g$ is increasing, the system is “attractive,” that is by the “basic coupling” (cf. Liggett [11]) if $dR$ and $dR'$ are initial measures of two processes $\xi_t$ and $\xi'_t$, and $dR \ll dR'$ in stochastic order, then the distributions of $\xi_t$ and $\xi'_t$ are similarly stochastically ordered [11]. We also note, when $p$ is symmetric, that $\mu_\rho$ and $\nu_\rho$ are reversible with respect to $\mathcal{L}_N$, and $L_N$ and $L^{env}_N$ respectively.

From this point, to avoid uninteresting compactness issues, we define every process in a finite time interval $[0, T]$, where $T < \infty$ is fixed. Let $T$ be the unit torus and let $\mathcal{M}_+(T)$ be the set of positive Radon measures in $T$.

For a continuous, positive function $\rho_0 : T \to \mathbb{R}_+$, define $\mu^N = \mu^N_{\rho_0}$ as the product measure in $\Omega_N$ given by $\mu^N_{\rho_0} (\eta(x) = k) = \mu_{\rho_0(x/N)} (\eta(x) = k)$.

Consider the process $\xi_t^N = : \xi_t^N \cdot \mathcal{N}_2$, generated by $N^2 \mathcal{L}_N$ starting from initial measure $\mu^N$. Define the process $\pi_t^{N,0}$ in $\mathcal{D}([0, T], \mathcal{M}_+(T))$ as

$$
\pi_t^{N,0}(du) = \frac{1}{N} \sum_{x \in \mathcal{N}_N} \xi_t^N(x) \delta_{x/N}(du),
$$

where $\delta_u$ is the Dirac distribution at point $u$.

The next result, “hydrodynamics,” under the assumption $p(\cdot)$ is mean-zero, is well known (cf. De Masi-Presutti [1], Kipnis-Landim [7]).

**Theorem 1.1.** For each $0 \leq t \leq T$, $\pi_t^{N,0}$ converges in probability to the deterministic measure $\rho(t, u)du$, where $\rho(t, u)$ is the solution of the hydrodynamic equation

$$
\begin{align*}
\partial_t \rho &= a^2 \partial_x^2 \rho(ho) \\
\rho(0, u) &= \rho_0(u),
\end{align*}
$$

(1.5)
and \( \varphi(\rho) = \int g(\xi(0))d\mu_\rho. \)

We now state results for the tagged particle motion. Define the product measure \( \nu^N = \nu^N_{\rho_0} \) in \( \Omega^N \) given by \( \nu^N_{\rho_0}(\eta(x) = k) = \nu_{\rho_0(x/N)}(\eta(x) = k) \), and let \( \eta_{N^2} \) be the process generated by \( N^2L_N \) and starting from the initial measure \( \nu^N. \) Define the empirical measure \( \pi^N_t \) in \( D([0,T], M_+(\mathbb{T})) \) by

\[
\pi^N_t(du) = \frac{1}{N} \sum_{x \in \Omega_N} \eta^N_t(x)\delta_{x/N}(du).
\]

Let also \( X^N_N = X_{N^2t} \) be the position of the tagged particle at time \( N^2t. \)

Define also the continuous function \( \psi : \mathbb{R} \to \mathbb{R} \) by

\[
\psi(\rho) = \int \frac{g(\eta(0))}{\eta(0)} \, d\nu_\rho.
\]

Note \( \psi(\rho) = \varphi(\rho)/\rho \) for \( \rho > 0, \) and \( \psi(0) = g(1). \) The first main result of the article is to identify the scaling limit of the tagged particle as a diffusion process:

**Theorem 1.2.** Let \( x^N_t = X^N_{N^2t} \) be the rescaled position of the tagged particle for the process \( \xi^N_t. \) Then, \( \{x^N_t : t \in [0,T]\} \) converges in distribution in the uniform topology to the diffusion \( \{x_t : t \in [0,T]\} \) defined by the stochastic differential equation

\[
dx_t = \sigma \sqrt{\psi(\rho(t,x_t))} \, dB_t,
\]

where \( B_t \) is a standard Brownian motion on \( \mathbb{T}. \)

In terms of this characterization, we can describe the evolution of the empirical measure as seen from the tagged particle:

**Theorem 1.3.** We have \( \{\pi^N_t : t \in [0,T]\} \) converges in distribution with respect to the Skorohod topology on \( D([0,T], M_+(\mathbb{T})) \) to the measure-valued process \( \{\rho(t,u + x_t)du : t \in [0,T]\} \), where \( \rho(t,u) \) is the solution of the hydrodynamic equation \( (1.5) \) and \( x_t \) is given by \( (1.6) \).

When the rate \( g(k) = 1\{k \geq 1\} \), scaling limits of a “second-class” particle \( \mathcal{X}_t \) can also be captured. Informally, such a particle must wait until all the other particles, say “first-class” particles, have left its position before it can displace by \( j \) with rate \( p(j) \). More precisely, its dynamics can be described in terms of its reference frame motion. For an initial configuration \( \xi \) such that \( \xi(0) \geq 1 \), let \( \zeta_x(x) = \xi_x(x+X_t) - \delta_{0,x} \), where \( \delta_{a,b} \) is Kronecker’s delta, be the system of first-class particles in the reference frame of the second-class particle. The generator \( \mathcal{L}_N \) takes form \( \mathcal{L}_N = \mathcal{L}^{\rho \nu}_N + \mathcal{L}^{\rho p}_N \), where

\[
(\mathcal{L}^{\rho \nu}_N f)(\zeta) = \sum_{x \in \Omega_N} \sum_z p(z)1\{\zeta(x) \geq 1\} [f(\zeta^{x,z}) - f(\zeta)],
\]

\[
(\mathcal{L}^{\rho p}_N f)(\zeta) = \sum_z p(z)1\{\zeta(0) = 0\} [f(\tau_z \zeta) - f(\zeta)]
\]

where \( \tau_z \) is the pure spatial translation by \( z, \) \( (\tau_z \zeta)(y) = \zeta(y+z) \) for \( y \in \mathbb{T}. \)

Then, as for the regular tagged particle, we have

\[
\mathcal{X}_t = \sum_j j \mathcal{N}_t(j) = \sum_j j \mathcal{M}_t(j) + m \int_0^t 1\{\zeta_x(0) = 0\} \, ds = \sum_j j \mathcal{M}_t(j)
\]
where, \( m = \sum_j jp(j) = 0 \) is the mean drift, \( \mathcal{N}_t(j) \) is the counting process of translations of size \( j \) up to time \( t \), and \( \mathcal{M}_t(j) = \mathcal{N}_t(j) - p(j) \int_0^t 1\{\zeta_s(0) = 0\}ds \) are the associated martingales. As before, since \( \mathcal{M}_t^j(j) - p(j) \int_0^t 1\{\zeta_s(0) = 0\}ds \) are orthogonal martingales, the quadratic variation of \( \mathcal{X}_t \) is \( \langle \mathcal{X} \rangle_t = \sigma^2 \int_0^t 1\{\zeta_s(0) = 0\}ds \).

For the second-class reference process \( \zeta_t \), under the assumption \( p(\cdot) \) is symmetric, the family \( d\kappa_{\rho} = (1 + \rho)^{-1}(\zeta(0) + 1)d\mu_\rho \) for \( \rho > 0 \) are invariant. We remark that symmetry of \( p(\cdot) \) is needed to show \( \kappa_\rho \) are invariant with respect to the second-class tagged process.

Let \( \kappa^N = \kappa_\rho^N(\cdot) \) be the product measure with \( \kappa_{\rho(x/N)}^N(\zeta(x) = k) = \kappa_{\rho(x)}(\zeta(x) = k) \). Let also \( \zeta^N_t = \zeta_{N^2t} \) be the process generated by \( N^2 \mathcal{Q}_N \) starting from \( \kappa^N \). Correspondingly, define empirical measure \( \pi_t^{N,1} = (1/N) \sum_{x \in \mathcal{T}_N} \zeta^N_t(\delta_{x/N}(du)) \). In addition, let

\[
\chi(\rho) = \int 1\{\zeta(0) = 0\}d\kappa_\rho = \frac{1}{1 + \rho} \int 1\{\zeta(0) = 0\}d\mu_\rho = \frac{1}{(1 + \rho)^2}.
\]

In the case \( g(k) = 1\{k \geq 1\} \), \( \varphi(\rho) = \rho/(1 + \rho) \). Denote by \( \rho^1 \) the solution of (1.3) with such function \( \varphi \). We may now state results for the second-class tagged motion.

**Theorem 1.4.** Suppose \( p(\cdot) \) is symmetric. Let \( y^N_t = \mathcal{X}_t^N/N \) be the rescaled position of the second-class tagged particle for the process \( \zeta^N_t \). Then, \( \{y^N_t : t \in [0, T]\} \) converges in distribution in the uniform topology to the diffusion \( \{y_t : t \in [0, T]\} \) defined by the stochastic differential equation

\[
dy_t = \sigma \sqrt{\chi(\rho^1(t, y_t))} dB_t,
\]

where \( B_t \) is a standard Brownian motion on \( \mathbb{T} \).

**Theorem 1.5.** Suppose \( p(\cdot) \) is symmetric. Then, \( \{\pi_t^{N,1} : t \in [0, T]\} \) converges in distribution with respect to the Skorokhod topology on \( \mathcal{D}([0, T], \mathcal{M}_+(\mathbb{T})) \) to the measure-valued process \( \rho^1(t, u + y_t)du : t \in [0, T]\} \) where \( y_t \) is given by (1.7).

The outline of the proofs of Theorems 1.2, 1.3, 1.4 and 1.5 are given at the end of this section. We now state the main replacement estimate with respect to process \( \eta^N_t \) for a (regular) tagged particle. A similar estimate holds with respect to process \( \zeta^N_t \) and a “second-class” particle, stated in the proof of Theorem 1.4. As remarked earlier, this replacement estimate is the main ingredient to show Theorems 1.2 and 1.5.

Denote by \( \mathbb{P}_\nu \) the probability measure in \( \mathcal{D}([0, T], \Omega_N) \) induced by the process \( \eta^N_t \), starting from initial measure \( \nu \), and by \( \mathbb{E}_\nu \) the corresponding expectation. When \( \nu = \nu^N \), we abbreviate \( \mathbb{P}_{\nu,\nu}^N = \mathbb{P}^N \) and \( \mathbb{E}_{\nu,\nu}^N = \mathbb{E}^N \). With respect to process \( \zeta^N_t \), denote \( \mathbb{P}_\mu \) the probability measure in \( \mathcal{D}([0, T], \Omega_N) \) starting from measure \( \mu \), and \( \mathbb{E}_\mu \) the associated expectation. Denote also by \( E_{\mu}[h] \) and \( (h)_\mu \) the expectation of a function \( h : \Omega_N \rightarrow \mathbb{R} \) with respect to the measure \( \mu \); when \( \mu = \nu_\rho \), let \( E_{\rho}[h] \), \( (h)_\rho \) stand for \( E_{\nu_\rho}[h] \), \( (h)_{\nu_\rho} \). Define also inner product \( \langle f, g \rangle_\mu = E_{\mu}[f\bar{g}] \), and covariance \( \langle f; g \rangle_\mu = E_{\mu}[f\bar{g}] - E_{\mu}[f]E_{\mu}[g] \) with the same convention when \( \mu = \nu_\rho \). To simplify notation, we will drop the superscript \( N \) in the speeded-up process \( \eta^N_t \).
For $\varepsilon > 0$ and $l \geq 0$, let

$$\eta^l(x) = \frac{1}{2l+1} \sum_{|y| \leq l} \eta(x+y).$$

**Theorem 1.6.** Let $h : \mathbb{N} \to \mathbb{R}_+$ be a positive, bounded, Lipschitz function such that there exists a constant $C$ such that $h(k) \leq C|g(k)/k|$ for $k \geq 1$. Then,

$$\lim_{l \to \infty} \lim_{\varepsilon \to 0} \lim_{e \to 0} \limsup_{N \to \infty} E_{\pi} \left[ \left| \int_0^t h(\eta_s(0)) - \frac{1}{eN} \sum_{x=1}^{eN} \tilde{H}_1(\eta_s^N(x)) \, ds \right| \right] = 0,$$

where $H(\rho) = E_{\nu}[h(\eta(0))]$, $H_1(\eta) = H(\eta^0(0))$, and $\tilde{H}_1(\rho) = E_{\nu}[H_1]$.

We now give the outlines of the proof of the main theorems.

**Proofs of Theorems 1.2 and 1.3.** First, the replacement estimate, Theorem 1.6 applies when $h(k) = g(k)/k$: Under the assumptions on $g$, clearly $h$ is positive, bounded, and Lipschitz. Given Theorem 1.6, the proof of the main theorems straightforwardly follow the same steps as in [6]. Namely, (1) tightness is proved for $(x^N_t, A^N_t, \pi^N_t, \eta^N_t)$ where $A^N_t = \langle x^N_t \rangle$ is the quadratic variation of the martingale $x^N_t$. (2) Using the hydrodynamic limit, Theorem 1.1, one determines the limit points of $\pi^N_t$, and $\pi^N_t = \tau_{x^N} \pi^N_t$. Limit points of $A^N_t$ are obtained through the replacement estimate, Theorem 1.6. Finally, one obtains limits of $x^N_t$ are characterized as continuous martingales with certain quadratic variations. Theorems 1.2 and 1.3 follow now by Levy’s theorem. More details on these last points can be found in [6].

**Proofs of Theorems 1.4 and 1.5.** The proofs follow the same scheme as for Theorems 1.2 and 1.3, given a replacement estimate. One can rewrite Theorem 1.6 in terms of $\zeta^N$:

$$\lim_{l \to \infty} \lim_{\varepsilon \to 0} \lim_{e \to 0} \limsup_{N \to \infty} E_{\sec} \left[ \left| \int_0^t \kappa(\zeta_s(0)) - \frac{1}{eN} \sum_{x=1}^{eN} \tilde{H}_1(\zeta^N_s(x)) \, ds \right| \right] = 0.$$

Here, $h(k) = 1[k = 0]$, $H(\rho) = E_{\nu}[h(\zeta(0))]$, $H(\zeta) = H(\zeta^l(0))$, and $\tilde{H}_1(\rho) = E_{\nu}[H_1]$. Also, $E_{\sec}$ is the process expectation with respect to $\zeta^N$.

Given $d\kappa = (1 + \rho)^{-1} d\mu + \rho (1 + \rho)^{-1} d\nu$, the proof of this replacement follows quite closely the proof of Theorem 1.6 with straightforward modifications.

The plan of the paper now is to give some spectral gap estimates, “global,” “local 1-block” and “local 2-blocks” estimates in sections 2, 3, 4, and 5, which are used to give the proof of Theorem 1.6 in Section 6.2.

For simplicity in the proofs, we will suppose that $p(\cdot)$ is symmetric, and nearest-neighbor, but our results hold, with straightforward modifications, when $p(\cdot)$ is finite-range, irreducible, and mean-zero, because mean-zero zero-range processes are gradient processes.
2. Spectral gap estimates

We discuss some spectral gap bounds which will be useful in the sequel. For \( l \geq 0 \), let \( \Lambda_l = \{ x : |x| \leq l \} \) be a cube of length \( 2l + 1 \) around the origin, and let \( \nu^\Lambda_l \) and \( \mu^\Lambda_l \) be the measures \( \nu^\Lambda_l \) and \( \mu^\Lambda_l \) restricted to \( \Lambda_l \).

For \( j \geq 0 \), define the sets of configurations \( \Sigma_{\Lambda_l,j} = \{ \eta \in \mathbb{N}_0^{\Lambda_l} : \sum_{x \in \Lambda_l} \eta(x) = j \} \), and \( \Sigma^*_{\Lambda_l,j} = \{ \eta \in \mathbb{N}_0^{\Lambda_l} : \eta(0) \geq 1; \sum_{x \in \Lambda_l} \eta(x) = j \} \). Define also the canonical measures \( \nu_{\Lambda_l,j}(\cdot) = \nu_p^\Lambda_l(\cdot|\Sigma_{\Lambda_l,j}) \) and \( \mu_{\Lambda_l,j}(\cdot) = \mu_p^\Lambda_l(\cdot|\Sigma_{\Lambda_l,j}) \). Note that both \( \nu_{\Lambda_l,j} \) and \( \mu_{\Lambda_l,j} \) do not depend on \( \rho \).

Denote by \( \mathcal{L}_{\Lambda_l}, \mathcal{L}_{\Lambda_l}^{env} \) the restrictions of the generators \( \mathcal{L}_N, \mathcal{L}_N^{env} \) on \( \Sigma_{\Lambda_l,j}, \Sigma^*_{\Lambda_l,j} \), respectively. These generators are obtained by restricting the sums over \( \mathbb{N}_0^{\Lambda_l} \) and \( \mathbb{N}_0^{\Lambda_l} \) with respect to \( \Sigma_{\Lambda_l,j}, \Sigma^*_{\Lambda_l,j} \), respectively. Denote the Dirichlet forms \( D(\mu_{\Lambda_l,j}, f) = \langle f, (-\mathcal{L}_{\Lambda_l}) f \rangle_{\mu_{\Lambda_l,j}} \) and \( D(\nu_{\Lambda_l,j}, f) = \langle f, (-\mathcal{L}_{\Lambda_l}^{env}) f \rangle_{\nu_{\Lambda_l,j}} \). One can compute

\[
D(\mu_{\Lambda_l,j}, f) = \frac{1}{2} \sum_{x \in \Lambda_l} p(y - x) E_{\mu_{\Lambda_l,j}} \left[ g(\eta(x))(f(\eta^x,y) - f(\eta))^2 \right]
\]

\[
D(\nu_{\Lambda_l,j}, f) = \frac{1}{2} \sum_{x \in \Lambda_l \setminus \{0\}} \sum_{y \in \Lambda_l} p(y - x) E_{\nu_{\Lambda_l,j}} \left[ g(\eta(x))(f(\eta^x,y) - f(\eta))^2 \right] + \frac{1}{2} \sum_{z \in \Lambda_l} p(z) E_{\nu_{\Lambda_l,j}} \left[ g(\eta(0)) \frac{\eta(0) - 1}{\eta(0)} (f(\eta^0,z) - f(\eta))^2 \right].
\]

Let \( W(l,j) \) and \( W^{env}(l,j) \) be the inverse of the spectral gaps of \( \mathcal{L}_{\Lambda_l} \) and \( \mathcal{L}_{\Lambda_l}^{env} \) with respect to \( \Sigma_{\Lambda_l,j} \) and \( \Sigma^*_{\Lambda_l,j} \), respectively. In particular, the following Poincaré inequalities are satisfied: For all \( L^2 \) functions,

\[
\langle f; f \rangle_{\mu_{\Lambda_l,j}} \leq W(l,j) D(\mu_{\Lambda_l,j}, f)
\]

\[
\langle f; f \rangle_{\nu_{\Lambda_l,j}} \leq W^{env}(l,j) D(\nu_{\Lambda_l,j}, f)
\]

In the next two lemmas, we do not assume that \( g \) is increasing. We first relate the environment spectral gap to the untagged process spectral gap.

Lemma 2.1. Suppose on \( \Sigma^*_{\Lambda_l,j} \) that \( a_1^{-1} \leq \eta(0)/g(\eta(0)) \leq ja_0^{-1} \). Then, for \( j \geq 1 \), we have that \( W^{env}(l,j) \leq (a_1 a_0^{-1})^2 W(l,j - 1) \).

Proof. Note \( E_{\mu_p}[g(\eta(0))f(\eta)] = \varphi(\rho) E_{\mu_p}[f'(\eta)] \) with \( f'(\eta) = f(\eta + \vartheta_0) \), where we recall \( \vartheta_0 \) is the configuration with exactly one particle at the origin. By a suitable change of variables one can show that \( D(\mu_{\Lambda_l,j-1}, f') \leq a_1 a_0^{-1} j D(\nu_{\Lambda_l,j}, f) \).

By the assumption on \( g \), for every \( c \in \mathbb{R} \),

\[
E_{\nu_{\Lambda_l,j}}[(f - E_{\nu_{\Lambda_l,j}} f)^2] \leq \frac{E_{\mu_p}[g(\eta(0))(f - c)^2 1\{\Sigma^*_{\Lambda_l,j}\}]}{E_{\mu_p}[g(\eta(0)) 1\{\Sigma^*_{\Lambda_l,j}\}]} \leq a_1 a_0^{-1} j \frac{E_{\mu_p}[g(\eta(0))(f - c)^2 1\{\Sigma^*_{\Lambda_l,j}\}]}{E_{\mu_p}[g(\eta(0)) 1\{\Sigma^*_{\Lambda_l,j}\}]}.
\]

The change of variables \( \eta' = \eta - \vartheta_0 \) and an appropriate choice of the constant \( c \) permits to rewrite last expression as

\[
a_1 a_0^{-1} j E_{\mu_{\Lambda_l,j-1}}[(f' - E_{\mu_{\Lambda_l,j-1}} f')^2] \leq a_1 a_0^{-1} j W(l,j - 1) D(\mu_{\Lambda_l,j-1}, f') ,
\]
where the last inequality follows from the spectral gap for the zero range process. By the observation made at the beginning of the proof, this expression is bounded by
\[(a_1 a_0^{-1})^2 W(l, j - 1) D(\nu_{\Lambda_l}, f),\]
which concludes the proof of the lemma.

**Lemma 2.2.** Suppose \( g \) satisfies \( a_0 \leq g(k) \leq a_1 \) for \( k \geq 1 \), and \( \lim_{k \to \infty} g(k) = L \). For every \( \alpha > 0 \), there is a constant \( B = B_\alpha \) such that \( W(l, j) \leq B'(1 + \alpha)^l(l + j)^2 \).

**Proof.** We need only establish, for all \( L^2 \) functions \( f \), that
\[(f; f)_{\mu_{\Lambda_l}} \leq B'(1 + \alpha)^l(l + j)^2 D(\mu_{\Lambda_l}, f).\]

To argue the bound, we make a comparison with the measure \( \mu_{\Lambda_l} \) when \( g(k) = 1 \{ k \geq 1 \} \). Denote this measure by \( \mu_{\Lambda_l} \), and recall, by conversion to the simple exclusion process (cf. [10, Example 1.1], [12]), that
\[E_{\mu_{\Lambda_l}}[(f - E_{\mu_{\Lambda_l}} f)^2] \leq b_0(l + j)^2 D_{\mu_{\Lambda_l}}(f) \quad (2.1)\]
for some finite constant \( b_0 \). Write
\[E_{\mu_{\Lambda_l}}[(f - E_{\mu_{\Lambda_l}} f)^2] = \inf c E_{\mu_{\Lambda_l}}[(f - c)^2] = \inf \sum_j \prod_{x=-l}^{l} g^{n(x)}(\eta(x)) (f(\eta) - c)^2 1\{ \sum x \eta(x) = j \} \cdot \frac{\sum_{x} \Pi_{x=-l}^{l} g^{n(x)}(\eta(x)) 1\{ \sum x \eta(x) = j \}}{\sum_{x} \Pi_{x=-l}^{l} g^{n(x)}(\eta(x))}.\]

Without loss of generality, we may now assume that \( L = 1 \) since we can replace \( g \) by its scaled version, \( g' = g/L \), in the above expression.

For \( \beta > 0 \), let \( r_0 \) be so large that \( 1 - \beta \leq g(z) \leq 1 + \beta \) for \( z \geq r_0 \). Then,
\[a_1^{-r_0} (1 + \beta)^{\eta(x)} \leq \frac{1}{g(\eta(x))!} \leq a_0^{-r_0} (1 - \beta)^{-\eta(x)}.\]

This bound is achieved by overestimating the first \( r_0 \) factors by the bound \( a_0 \{ z \geq 1 \} \leq g(z) \leq a_1 \), and the remaining factors by
\[(1 + \beta)^{-\eta(x)} \leq \frac{1}{\Pi_{z=r_0+1}^{\eta(x)} g(z)} \leq (1 - \beta)^{-\eta(x)}\]
where by convention an empty product is defined as 1.

As there are \( 2l + 1 \) sites, we bound the right hand side of the displayed expression appearing just below (2.1) by
\[(a_0^{-1} a_1)^{(2l+1)r_0} [(1 + \beta)(1 - \beta)^{-1}]^l E_{\mu_{\Lambda_l}}[(f - E_{\mu_{\Lambda_l}} f)^2].\]

By the spectral gap estimate (2.1) and the same bounds on the Radon-Nikodym derivative of \( d\mu_{\Lambda_l}/d\mu_{\Lambda_{l-1}} \), the previous expression is less than or equal to
\[(a_0^{-1} a_1)^{(2l+1)r_0} [(1 + \beta)(1 - \beta)^{-1}]^{l} b_0(l + j)^2 D(\mu_{\Lambda_l}, f).\]

We may now choose \( \beta = \beta(\alpha) \) appropriately to finish the proof. \( \square \)

We claim that for any constant \( C > 0 \),
\[\lim_{N \to \infty} \frac{1}{N} \max_{1 \leq j \leq C \log N} W_{env}(l, j) = 0. \quad (2.2)\]

Indeed, under the conditions (SL) this follows by Lemma 2.1 and by assumption (SL3). On the other hand, under the condition (B), by Lemma 2.2 we may choose
\( \alpha \) appropriately to have \( \max_{1 \leq j \leq C \log N} W(l, j) \leq C_2(l) N^{1/2} \). This proves (2.2) in view of Lemma 2.1.

3. “Global” Replacement

In this section, we replace the full, or “global” empirical average of a local, bounded and Lipschitz function, with respect to the process \( \eta_s \), in terms of the density field \( \pi_N \). The proof involves only a few changes to the hydrodynamics proof of [1] Theorem 3.2.1, and is similar to that in [6]. However, since the rate \( g \) is bounded, some details with respect to the “2-blocks” lemma below are different.

**Proposition 3.1 ("Global” replacement).** Let \( r : \Omega_N \to \mathbb{R} \) be a local, bounded and Lipschitz function. Then, for every \( \mu \), the rate \( g \) is bounded, some details with respect to the “2-blocks” lemma below are different.

**Proposition 3.1 ("Global” replacement).** Let \( r : \Omega_N \to \mathbb{R} \) be a local, bounded and Lipschitz function. Then, for every \( \delta > 0 \),

\[
\limsup_{\varepsilon \to 0} \limsup_{N \to \infty} \mathbb{P}^N \left[ \int_0^T \frac{1}{N} \sum_{x \in \mathbb{T}_N} \tau_x \nu_{\varepsilon N}(\eta_s) \, ds \geq \delta \right] = 0,
\]

where

\[
\nu_{\varepsilon}(\eta) = \left\lfloor \frac{1}{2\varepsilon + 1} \sum_{|y| \leq 2\varepsilon} \tau_y r(\eta) - \tau_y r(\eta(0)) \right\rfloor \text{ and } \tau(a) = E_{\mu_a}[r].
\]

Denote by \( \mathcal{H}(\mu|\nu) \) the entropy of \( \mu \) with respect to \( \nu \):

\[
\mathcal{H}(\mu|\nu) = \sup \left\{ \int f d\mu - \log \int e^f d\nu \right\},
\]

where the supremum is over bounded continuous functions \( f \).

We may compute, with respect to the product measures \( \nu_{\rho N}^N(\cdot) \) and \( \nu_{\rho} \), that the initial entropy \( \mathcal{H}(\nu_{\rho N}^N(\cdot)|\nu_{\rho}) \leq C_0 N \) for some finite constant \( C_0 \) depending only on \( \rho_0(\cdot) \) and \( g \). Let \( f_{\rho N}^N(\eta) \) be the density of \( \eta \) under \( \mathbb{P}^N \) with respect to a reference measure \( \nu_{\rho} \) for \( \rho > 0 \), and let \( \bar{f}_{\rho N}^N(\eta) = t^{-1} \int_0^t f_{\rho N}^N(\eta) ds \). By usual arguments (cf. Section V.2 [1]),

\[
\mathcal{H}_N(\bar{f}_{\rho N}^N) := \mathcal{H}(\bar{f}_{\rho N}^N d\nu_{\rho} | \nu_{\rho}) \leq C_0 N \text{ and } \mathcal{D}_N(\bar{f}_{\rho N}^N) := \left( \sqrt{\int_0^T \bar{f}_{\rho N}^N (-L_N \bar{f}_{\rho N}^N)} \right)^2 \leq \frac{C_0}{\sqrt{N}},
\]

where \( \langle u, v \rangle_\rho \) stands for the scalar product in \( L^2(\nu_{\rho}) \), as defined in the first section.

Consequently, to prove Proposition 3.1 it is enough to show, for any finite constant \( C \), that

\[
\limsup_{\varepsilon \to 0} \limsup_{N \to \infty} \sup_{\mathcal{H}_N(f) \leq C N} \mathcal{D}_N(f) \leq \mathcal{H}_N(\bar{f}_{\rho N}^N) \leq C_0 \sqrt{N},
\]

where the supremum is with respect to \( \nu_{\rho} \)-densities \( f \).

We may remove from the sum in (3.1) the integers \( x \) close to the origin, say \( |x| \leq 2 \varepsilon N \), as \( \nu_{\varepsilon N} \) is bounded. Now, the underlying reference measure \( \nu_{\rho} \) may be treated as homogeneous, and a standard strategy may be employed as follows.

Proposition 3.1 now follows from the two standard lemmas below. In this context, see also [1], and [7] where the same method is used to prove [1] Theorem 3.2.1 and [7] Lemma V.1.10 respectively.

**Lemma 3.2** (Global 1-block estimate).

\[
\limsup_{k \to \infty} \limsup_{N \to \infty} \mathbb{E}^N \left[ \int_0^T \frac{1}{N} \sum_{|x| > 2 \varepsilon N} \tau_x \nu_{k}(\eta_s) \, ds \right] = 0.
\]
The proof of Lemma 3.2 is the same as for \([6, \text{Lemma 5.2}]\), and follows the scheme of \([7, \text{Lemma V.3.1}]\), using that \(g\) has “sub-linear growth (SLG)”. Details are omitted here.

**Lemma 3.3** (Global 2-block estimate).

\[
\limsup_{k \to \infty} \limsup_{\varepsilon \to 0} \limsup_{N \to \infty} \mathbb{E}^N \left[ \int_0^T \frac{1}{2N \varepsilon + 1} \sum_{|y| \leq N \varepsilon} \frac{1}{N} \sum_{|x| > 3 \varepsilon N} |\eta^k_s(x + y) - \eta^k_s(x)| \, ds \right] = 0.
\]

**Proof.** We discuss in terms of modifications to the argument in \([7, \text{Section V.4}]\). The first step is to cut-off high densities. We claim that

\[
\limsup_{A \to \infty} \limsup_{k \to \infty} \limsup_{N \to \infty} \mathbb{E}^N \left[ \int_0^T \frac{1}{N} \sum_{|x| > 3 \varepsilon N} \eta^k_s(x) 1\{\eta^k_s(x) > A\} \, ds \right] = 0.
\]

To prove this assertion, we first replace the sum over \(x\) by a sum over all sites of \(T_N\). At this point, since the environment at time \(\eta_t\) is obtained from the system by a shift, we may replace the variable \(\eta_t\) by \(\xi_t\). We need therefore to estimate

\[
\mathbb{E}_{\mu_{\rho_0}} \left[ \int_0^T \frac{1}{N} \sum_{x \in T_N} \xi^k_s(x) 1\{\xi^k_s(x) > A\} \, ds \right].
\]

Let \(\bar{\rho} = \|\rho_0\|_{L^\infty}\), and note that \(\mu_{\rho_0}\) is stochastically dominated by \(\mu_{\bar{\rho}}\). By attractiveness we may replace \(\mu_{\rho_0}\) by \(\mu_{\bar{\rho}}\) in the previous expression and bound this expectation by

\[
\mathbb{E}_{\mu_{\bar{\rho}}} \left[ \int_0^T \frac{1}{N} \sum_{x \in T_N} (\xi^k_s(x))^2 \, ds \right].
\]

By Schwarz inequality, and noting that \(\mu_{\bar{\rho}}\) is invariant with respect to the untagged process \(\xi_s\), the last expression is of order \(A^{-1}\), which proves the claim.

In view of the truncation just proved and the entropy calculations presented at the beginning of this section, to prove the lemma it is enough to show that for every \(A > 0\),

\[
\limsup_{k \to \infty} \limsup_{N \to \infty} \sup_{\mathcal{H}_N(f) \leq C/N} \mathbb{E}^{N_A(f)} \left[ \frac{1}{2N \varepsilon + 1} \sum_{|y| \leq N \varepsilon} \frac{1}{N} \sum_{|x| > 3 \varepsilon N} W_{x,y}^{k,A}(\eta) \, d\nu_{\rho} \right] = 0.
\]

where

\[
W_{x,y}^{k,A}(\eta) = |\eta^k(x + y) - \eta^k(x)| 1\{\max\{\eta^k(x), \eta^k(x + y)\} \leq A\}.
\]

The argument is now the same as in the proof of Lemma 5.3 \([6]\) following \([7, \text{Section V.5}]\). \(\square\)

4. “LOCAL” ONE-BLOCK ESTIMATE

We now detail a “local” one-block limit. Let \(h : \mathbb{N}_0 \to \mathbb{R}\) be a bounded, Lipschitz function, and \(H(a) = E_{\nu_a}[h(\eta(0))]\). Define also

\[
V_l(\eta) = h(\eta(0)) - H(\eta^l(0)).
\]
Lemma 4.1 (One-block estimate). For every $0 \leq t \leq T$,
\[
\lim_{l \to \infty} \limsup_{N \to \infty} \mathbb{E}^N \left[ \left| \int_0^t V_l(\eta_s) \, ds \right| \right] = 0.
\]

Proof. The proof is in four steps.

Step 1. The first step is to introduce a truncation. Since the dynamics is not attractive, we cannot bound $\eta(0) > A$ for some constant $A$ in a simple way. However, by considering the maximum of such quantities over the torus, we may rewrite the maximum in terms of the original system $\xi_s$, which is attractive:
\[
\max_{x \in T_N} \eta_s(x) = \max_{x \in T_N} \xi_s(x).
\]
Also, by simple estimates, recalling $\bar{\rho} = \|\rho_0\|_\infty$, we have that
\[
P_{\nu_{\bar{\rho}L}^{(1)}} \left( \max_x \xi_s(x) \geq C \log N \right) = \mathbb{E}_{\mu_{\bar{\rho}L}} \left[ \frac{\xi_0(0)}{\rho_0(0)} \mathbf{1} \{ \max_x \xi_s(x) \geq C \log N \} \right] 
\leq \mathbb{E}_{\mu_{\bar{\rho}}} \left[ \frac{\xi_0(0)}{\rho_0(0)} \mathbf{1} \{ \max_x \xi_s(x) \geq C \log N \} \right].
\]

Under the stationary measure $\mu_{\bar{\rho}}$, the variables $\xi_s(x)$ are independent and identically distributed, with finite exponential moments of some order. Hence, by Chebyshev’s inequality, the last expression vanishes as $N \uparrow \infty$ for a well chosen constant $C = C_1$. Therefore, as $\eta(0) \leq \max_x \eta(x)$, it is enough to estimate
\[
\mathbb{E}^N \left[ \left| \int_0^t V_l(\eta_s) \mathbf{1} \{ G_{N,l} \} (\eta_s) \, ds \right| \right].
\]
where $G_{N,l} = \{ \eta : \eta'(0) \leq C_1 \log N \}$.

Step 2. Since the initial entropy $\mathcal{H}(\nu^{N}_{\bar{\rho}L}^{(1)}|\nu_{\rho})$ is bounded by $C_0 N$, by the entropy inequality,
\[
\mathbb{E}^N \left[ \left| \int_0^t V_l(\eta_s) \mathbf{1} \{ G_{N,l} \} (\eta_s) \, ds \right| \right] 
\leq \frac{C_0}{\gamma} + \frac{1}{\gamma N} \log \mathbb{E}_{\nu_{\rho}} \left[ \exp \left\{ \gamma N \left| \int_0^t V_l(\eta_s) \mathbf{1} \{ G_{N,l} \} (\eta_s) \, ds \right| \right\} \right].
\]
We can get rid of the absolute value in the previous integral, using the inequality $\exp(x) \leq e^x + e^{-x}$. By Feynman-Kac formula, the second term on the right hand side is bounded by $(\gamma N)^{-1} T \lambda_{N,l}$, where $\lambda_{N,l}$ is the largest eigenvalue of $N^2 L_N + \gamma N V_l \mathbf{1} \{ G_{N,l} \}$. Therefore, to prove the lemma, it is enough to show that $(\gamma N)^{-1} \lambda_{N,l}$ vanishes, as $N \uparrow \infty$ and then $l \uparrow \infty$, for every $\gamma > 0$.

Step 3. By the variational formula for $\lambda_{N,l}$,
\[
(\gamma N)^{-1} \lambda_{N,l} = \sup_f \left\{ \langle V_l \mathbf{1} \{ G_{N,l} \} f^2 \rangle_{\rho} - \gamma^{-1} N \langle f(-L_N f) \rangle_{\rho} \right\}, \quad (4.1)
\]
where the supremum is carried over all densities $f^2$ with respect to $\nu_{\rho}$. As the Dirichlet forms satisfy $\langle f(-L_{N}^{env} f) \rangle_{\rho} \leq \langle f(-L_N f) \rangle_{\rho}$ (cf. [7] equation (3.1)), we may bound the previous expression by a similar one where $L_N$ is replaced by $L^{env}_N$.

Denote by $\bar{f}_l$ the conditional expectation of $f^2$ given $\{ \eta(z) : z \in \Lambda_l \}$. Since $V_l \mathbf{1} \{ G_{N,l} \}$ depends on the configuration $\eta$ only through $\{ \eta(z) : z \in \Lambda_l \}$ and since

\[
\mathbb{E}^N \left[ \left| \int_0^t V_l(\eta_s) \mathbf{1} \{ G_{N,l} \} (\eta_s) \, ds \right| \right] 
\leq \mathbb{E}^N \left[ \left| \int_0^t \bar{f}_l(\eta_s) \mathbf{1} \{ G_{N,l} \} (\eta_s) \, ds \right| \right],
\]

we have
\[
\mathbb{E}^N \left[ \left| \int_0^t V_l(\eta_s) \mathbf{1} \{ G_{N,l} \} (\eta_s) \, ds \right| \right] 
\leq \mathbb{E}^N \left[ \left| \int_0^t \bar{f}_l(\eta_s) \mathbf{1} \{ G_{N,l} \} (\eta_s) \, ds \right| \right].
\]
the Dirichlet form is convex, the expression inside braces in (4.1) is less than or equal to
\[
\int V_i \{G_{N,j} \} \hat{f}_{i,j}^2 \, d\nu^{\Lambda_i}_\rho - \gamma^{-1}N \int \hat{f}_{i,j} (-L^{env}_{\Lambda_i} \hat{f}_{i,j}) \, d\nu^{\Lambda_i}_\rho.
\] (4.2)

The first term in this formula, decomposing in terms of canonical measures \(\nu_{\Lambda_i,j}\), is equal to
\[
\sum_{j=1}^{C_1 \log N} c_{i,j}(f) \int V_i \{G_{N,j} \} \hat{f}_{i,j}^2 \, d\nu_{\Lambda_i,j}
\]
where the value of the constant \(C_1\) changed and
\[
c_{i,j}(f) = \int_{\Sigma_{\Lambda_i,j}} \hat{f}_{i,j}^2 \, d\nu^{\Lambda_i}_\rho, \quad \hat{f}_{i,j}(\eta) = c_{i,j}(f)^{-1} \nu^{\Lambda_i}(\Sigma_{\Lambda_i,j}) \hat{f}_{i,j}(\eta).
\]
The sum starts at \(j = 1\) because there is always a particle at the origin. Note also that \(\sum_{j \geq 1} c_{i,j}(f) = 1\) and that \(\hat{f}_{i,j}(\cdot)\) is a density with respect to \(\nu_{\Lambda_i,j}\).

Also, the Dirichlet form term of (4.2) can be written as
\[
\gamma^{-1}N \sum_{1 \leq j \leq C_1 \log N} c_{i,j}(f) \int \hat{f}_{i,j} (-L^{env}_{\Lambda_i} \hat{f}_{i,j}) \, d\nu_{\Lambda_i,j}.
\]
In view of this decomposition, (4.1) is bounded above by
\[
\sup_{1 \leq j \leq C_1 \log N} \sup_f \left\{ \int V_i f^2 \, d\nu_{\Lambda_i,j} - \gamma^{-1}N \int f (-L^{env}_{\Lambda_i} f) \, d\nu_{\Lambda_i,j} \right\},
\]
where the second supremum is over all densities \(f^2\) with respect to \(\nu_{\Lambda_i,j}\).

Step 4. Recall that \(V_i(\eta) = h(\eta(0)) - H(\eta'(0))\). Let \(V_{i,j}(\eta) = V_i - E_{\nu_{\Lambda_i,j}}[V_i]\). By (2.2), \(N^{-1} \max_{1 \leq j \leq C_1 \log N} W^{env}(l,j)\) vanishes as \(N \uparrow \infty\). Then, as \(h\) is bounded, by Rayleigh expansion [7] Theorem A3.1.1], for \(j \leq C_1 \log N\) and sufficiently large \(N\),
\[
\int V_i f^2 \, d\nu_{\Lambda_i,j} - \gamma^{-1}N \int f (-L^{env}_{\Lambda_i} f) \, d\nu_{\Lambda_i,j}
\]
\[
\leq \int V_i \, d\nu_{\Lambda_i,j} + \frac{\gamma N^{-1}}{1 - 2\|V_i\|_{L^\infty} W^{env}(l,j)} \int V_{i,j} (\gamma N^{-1} V_{i,j}) \, d\nu_{\Lambda_i,j}
\]
\[
\leq \int V_i \, d\nu_{\Lambda_i,j} + 2\gamma N^{-1} \int V_{i,j} (\gamma N^{-1} V_{i,j}) \, d\nu_{\Lambda_i,j}.
\]

The second term is bounded as follows. By the spectral theorem, second term then is less than or equal to
\[
2 W^{env}(l,j) \gamma N^{-1} \int V_{i,j}^2 \, d\nu_{\Lambda_i,j} \leq 8\|h\|_{L^\infty}^2 W^{env}(l,j) \gamma N^{-1}.
\] (4.3)

This expression vanishes as \(N \uparrow \infty\) in view of (2.2).

On the other hand, the first term is written as
\[
\int V_i \, d\nu_{\Lambda_i,j} = \int h(\eta(0)) \, d\nu_{\Lambda_i,j} - H(j/2l + 1).
\]
By Lemma 4.2 below, this difference vanishes uniformly in \(j\) as \(l \uparrow \infty\). This proves that (4.1) vanishes as \(N \uparrow \infty\) and then \(l \uparrow \infty\), finishing the proof. \(\Box\)
Lemma 4.2. Let $h : \mathbb{N}_0 \to \mathbb{R}$ be a bounded Lipschitz function which vanishes at infinity. Then, we have

$$\limsup_{k \to \infty} \sup_{k \geq 1} \left| E_{\nu_{\lambda_1,k}}[h(\eta(0))] - E_{\nu_{\lambda_1,k}/|\lambda_1|}[h(\eta(0))] \right| = 0.$$  

Proof. The argument is in three steps.

Step 1. We first consider the case $1 \leq k \leq K_0$. By adding and subtracting $h(1)$, we need only estimate

$$\left| E_{\nu_{\lambda_1,k}}[h(\eta(0))] - h(1) \right|$$

and

$$\left| E_{\nu_{\lambda_1,k}/|\lambda_1|}[h(\eta(0))] - h(1) \right|. \quad (4.4)$$

The first term is bounded by $2\|h\|_{L^\infty} \nu_{\lambda_1,k}\{\eta(0) \geq 2\}$. To show that it vanishes as $l \uparrow \infty$, note that $\eta(0) \leq k$ and that $E_{\nu_{\lambda_1,k}}[\eta(0)] = k/(2l + 1)$ to write

$$\nu_{\lambda_1,k}\{\eta(0) \geq 2\} = \frac{1}{E_{\nu_{\lambda_1,k}}[\eta(0)]} E_{\nu_{\lambda_1,k}}[\eta(0) 1\{\eta(0) \geq 2\}] \leq (2l + 1) \nu_{\lambda_1,k}\{\eta(0) \geq 2\}.$$ 

For $2 \leq s \leq k$, we may write the canonical measure in terms of the grand canonical:

$$\mu_{\lambda_1,k}\{\eta(0) = s\} = \mu_p\{\eta(0) = s\} \frac{\mu_p\{\sum_{0 \leq |x| \leq l} \eta(x) = k - s\}}{\mu_p\{\sum_{0 \leq |x| \leq l} \eta(x) = k\}}$$

for any choice of the parameter $\rho$. Recall $\mu_{\lambda_1,k}^1$ is the canonical measure when $g(k) = 1\{k \geq 1\}$. In the numerator and the denominator, at least $2l - k$ sites receive no particles. We may therefore replace in these sites the rate $g$ by the rate constant equal to one with no cost. Since $a_0 \leq g(\ell) \leq a_1 \ell$, in the remaining sites we have that $C(k)^{-1} \leq a_0^2 \leq g(n)! \leq a_1^2 n! \leq C(k)$ if $n \leq k$. The previous expression is thus bounded above by

$$C(k) \mu_{\lambda_1,k}^1\{\eta(0) = s\} \leq C(k) \left( \frac{2l}{k - s} \right) \left( \frac{2l + 1}{k} \right) = O(l^{-s}).$$

To bound the second term in (4.4), we proceed in a similar way. The absolute value of the difference $E_{\nu_{\lambda_1,k}}[h(\eta(0))] - h(1)$ is bounded by $2\|h\|_{L^\infty} \nu_{\lambda_1,k}\{\eta(0) \geq 2\}$. Last probability is equal to $\rho^{-1} E_{\nu_{\lambda_1,k}}[\eta(0) 1\{\eta(0) \geq 2\}]$. Since $g(n) \geq a_0$, change of variables $\eta' = \eta - 2\delta_0$ permits to bound the previous expression by $C_0 \varphi(\rho)^2[\rho + 2]/\rho$ for some finite constant $C_0$. Since $g(n) \leq a_1 n$, $\varphi(\rho) \leq a_1 \rho$. In conclusion, the second term in (4.4) is bounded above by $C_0 \|h\|_{L^\infty} (k/l)^2$, which concludes the proof of Step 1.

Step 2. Next, we consider the case in which $K_0 \leq k \leq B|\lambda_1|$ for some $B < \infty$. By definition of the Palm measure, the difference $E_{\nu_{\lambda_1,k}}[h(\eta(0))] - E_{\nu_{\lambda_1,k}/|\lambda_1|}[h(\eta(0))]$ is equal to

$$\frac{|\lambda_1|}{k} \left\{ E_{\nu_{\lambda_1,k}}[\eta(0) h(\eta(0))] - E_{\nu_{\lambda_1,k}/|\lambda_1|}[\eta(0) h(\eta(0))] \right\}.$$ 

By [7] Corollary 1.7, Appendix 2.1, this expression is bounded above by $C_0 k^{-1}$ for some finite constant $C_0$. This expression can be made as small as need by choosing $K_0$ large.

Step 3. Finally, we consider the case $k \geq B|\lambda_1|$. We shall take advantage of the fact that $h$ vanishes at infinity. Fix $A > 0$ to bound $E_{\nu_{\lambda_1,k}}[h(\eta(0))]$ by

$$E_{\nu_{\lambda_1,k}}[h(\eta(0)) 1\{\eta(0) \leq A\}] + \sup_{x \geq A} h(x)$$

for any choice of the parameter $\rho$. Recall $\mu_{\lambda_1,k}^1$ is the canonical measure when $g(k) = 1\{k \geq 1\}$. In the numerator and the denominator, at least $2l - k$ sites receive no particles. We may therefore replace in these sites the rate $g$ by the rate constant equal to one with no cost.
By definition of the Palm measure and since the density \( k/|\Lambda_l| \) is bounded below by \( B \), the first term is less than or equal to
\[
\frac{\|h\|_{L^\infty} |\Lambda_l|}{k} E_{\nu_{\Lambda_l/k}}[\eta(0) 1\{\eta(0) \leq A\}] \leq \frac{A\|h\|_{L^\infty}}{B}.
\]
In view of the previous estimates, we see that the expectation \( E_{\nu_{\Lambda_l/k}}[h(\eta(0))] \) can be made arbitrarily small by choosing \( A \) and \( B \) sufficiently large. The expectation \( E_{\nu_{\Lambda_l/k}}[h(\eta(0))] \) can be estimated similarly. \( \square \)

5. Local two-blocks estimate

In this section we show how to go from a box of size \( t \) to a box of size \( \epsilon N \).

**Lemma 5.1** (Two-blocks estimate). *Let \( H : \mathbb{R}_+ \to \mathbb{R} \) be a bounded, Lipschitz function, which vanishes at infinity, \( \lim_{x \to \infty} H(x) = 0 \). Then, for every \( t > 0 \),
\[
\lim_{l \to \infty} \lim_{\epsilon \to 0} \lim_{N \to \infty} \mathbb{E}^N \left[ \left| \int_0^t \left\{ H(\eta^\epsilon_k(0)) - \frac{1}{\epsilon N} \sum_{x=1}^{\epsilon N} H(\eta^\epsilon_k(x)) \right\} \, ds \right| \right] = 0. \tag{5.1}
\]*

**Proof.** The proof is handled in several steps.

**Step 1.** As \( H \) is bounded, the expectation in (5.1) is bounded
\[
\frac{1}{\epsilon N} \sum_{x=4l+2}^{\epsilon N} \mathbb{E}^N \left[ \left| \int_0^t \left\{ H(\eta^\epsilon_k(0)) - H(\eta^\epsilon_k(x)) \right\} \, ds \right| \right] + \frac{C_0 \|H\|_{L^\infty}}{\epsilon N}
\]
for some finite constant \( C_0 \). Hence, we need to estimate, uniformly over \( 4l+2 \leq x \leq \epsilon N \),
\[
\mathbb{E}^N \left[ \left| \int_0^t \left\{ H(\eta^\epsilon_k(0)) - H(\eta^\epsilon_k(x)) \right\} \, ds \right| \right].
\]

**Step 2.** Write
\[
H(\eta^\epsilon_k(0)) - H(\eta^\epsilon_k(x)) = H(\eta^\epsilon_k(0)) - H(\eta^\epsilon_k(2l+1)) + H(\eta^\epsilon_k(2l+1)) - H(\eta^\epsilon_k(x)).
\]

We now claim that
\[
\lim_{l \to \infty} \lim_{N \to \infty} E_N \left[ \left| \int_0^t \left\{ H(\eta^\epsilon_k(0)) - H(\eta^\epsilon_k(2l+1)) \right\} \, ds \right| \right] = 0.
\]
Indeed, since \( H(\eta^\epsilon_k(0)) - H(\eta^\epsilon_k(2l+1)) \) is a function of \( \Lambda_l = \{-l, \ldots, 3l+1\} \), we may apply the “local 1-block” argument for Lemma 4.2 up to (4.3), with respect to \( V_t^\epsilon = H(\eta^\epsilon_k(0)) - H(\eta^\epsilon_k(2l+1)) \). Now, in the last line of the proof of Lemma 4.1 instead of using Lemma 4.2 we use Lemma 5.4 to show the expectation under the canonical measure \( \nu_{\Lambda_l/k} \) vanishes, \( \lim_{l \to \infty} \sup_{k \geq 1} E_{\nu_{\Lambda_l/k}}[V_t^\epsilon] = 0 \).

**Step 3.** Therefore, we need only estimate when the integrand is \( H(\eta^\epsilon_k(2l+1)) - H(\eta^\epsilon_k(x)) \). As for the “local 1-block” development (Lemma 4.1), we may introduce a truncation, and restrict to the set \( G_{N,l,x} = \{ \eta : \eta^\epsilon_k(2l+1) + \eta^\epsilon_k(x) \leq 2C_1 \log N \} \). That is, we need only bound, uniformly over \( x \),
\[
\mathbb{E}^N \left[ \left| \int_0^t \left\{ H(\eta^\epsilon_k(2l+1)) - H(\eta^\epsilon_k(x)) \right\} \, ds \right| \right].
\]
Step 4. Following the first part of the proof of Lemma [4.1] appealing to entropy estimates and eigenvalue estimates, we need only to bound, uniformly in \(4l + 2 \leq x \leq \epsilon N\),

\[
\sup_f \left\{ \langle H(\eta^l(2l + 1)) - H(\eta^l(x)) \rangle \{G_{N,l,x} \} , f^2 \rangle \rho - N \gamma^{-1} \langle f, (-L_N f) \rangle \rho \right\},
\]

(5.2)

where the supremum is over all density functions \(f^2\) with \(\int f^2 d\nu_\rho = 1\).

Since \(V_{l,x}(\eta) = H(\eta^l(2l + 1)) - H(\eta^l(x))\) does not involve the origin, we can avoid details involving the inhomogeneity at point 0 in the following. Define disjoint blocks \(\Lambda'_l = \{l + 1, \ldots, 3l + 1\}\) and \(\Lambda_l(x) = \{x - l, \ldots, x + l\}\). Let \(L_{\Lambda_l,x}\) be the restriction of \(L_N^{env}\) to the set \(\Lambda_{l,x} = \Lambda'_l \cup \Lambda_l(x)\), and define also \(L_{l,x}\) by

\[
L_{l,x}f(\eta) = \frac{1}{2} g(\eta(x - l)) \left[ f(\eta^{x-l,3l+1}) - f(\eta) \right] + \frac{1}{2} g(\eta(3l + 1)) \left[ f(\eta^{3l+1,x-l}) - f(\eta) \right].
\]

The operator \(L_{l,x}\) corresponds to zero-range dynamics where particles jump between endpoints \(3l + 1\) and \(x - l\).

As \(x \leq \epsilon N\), by adding and subtracting at most \(\epsilon N\) terms (cf. [7, p. 94-95], [17, equation (3.1)]), we have that

\[
\langle f(-L_{l,x}f) \rangle \leq \epsilon N \langle f(-L_N^{env} f) \rangle.
\]

Hence,

\[
\langle f, - (N \gamma^{-1} L_{\Lambda_l,x} + \epsilon^{-1} \gamma^{-1} L_{l,x}) f \rangle \rho \leq 2N \gamma^{-1} \langle f(-L_N f) \rangle \rho,
\]

and we may replace \(N \gamma^{-1} L_N\) in (5.2) by \((1/2)(N \gamma^{-1} L_{\Lambda_l,x} + \epsilon^{-1} \gamma^{-1} L_{l,x})\).

Step 5. To simplify notation, we shift the indices so that the blocks are to the left and right of the origin. In particular, let \(\Lambda_{l}^- = \{-2l + 1, \ldots, -1\}\), \(\Lambda_{l}^+ = \{1, \ldots, 2l + 1\}\) and \(\Lambda_{l}^\pm = \Lambda_{l}^- \cup \Lambda_{l}^+\). Configurations of \(N_{0}^{\Lambda_l^-}\) will be denoted by the Greek letter \(\eta\), while configurations of \(N_{0}^{\Lambda_l^+}\) are denoted by the Greek letter \(\zeta\). Recall \(\mathcal{D}_z\) stands for the configuration with no particles but one at \(z\).

Consider the generator \(L_{N,z,l}^{\pm}\) with respect to \(N_{0}^{\Lambda_l^-}\), \(L_{N,z,l} = NL_{l}^- + NL_{l}^+ + \epsilon^{-1} L_l^0\).

Here,

\[
(L_{l}^- f)(\eta, \zeta) = \sum_{x,y \in \Lambda_{l}^-} p(y - x) g(\eta(x)) \left[ f(\eta^{x,y}, \zeta) - f(\eta, \zeta) \right],
\]

\[
(L_{l}^+ f)(\eta, \zeta) = \sum_{x,y \in \Lambda_{l}^+} p(y - x) g(\zeta(x)) \left[ f(\eta, \zeta^{x,y}) - f(\eta, \zeta) \right],
\]

\[
(L_l^0 f)(\eta, \zeta) = (1/2) g(\eta(-1)) \left[ f(\eta - \partial_{-1}, \zeta + \partial_1) - f(\eta, \zeta) \right] + (1/2) g(\zeta(1)) \left[ f(\eta + \partial_{-1}, \zeta - \partial_1) - f(\eta, \zeta) \right].
\]

Note that inside each set \(\Lambda_{l}^\pm\) particles jump at rate \(N\) while jumps between sets are performed at rate \(\epsilon^{-1}\).
Recall $\mu_{\rho}^{\Lambda_1^*}$, $\mu_{\rho}^{\Lambda_2^*}$, $\mu_{\rho}^{\Lambda_0^*}$ are the restrictions of $\mu_{\rho}$ to $N_0^{\Lambda_1^*}$, $N_0^{\Lambda_2^*}$, $N_0^{\Lambda_0^*}$, respectively. The Dirichlet forms associated to the generators $L_1^-, L_1^+, L_0^2$ are given by

$$D_{\Lambda_1^*}(\mu_{\rho}^{\Lambda_1^*}, f) = \langle f, (-L_1^- f) \rangle_{\mu_{\rho}^{\Lambda_1^*}}, \quad D_{\Lambda_2^*}(\mu_{\rho}^{\Lambda_2^*}, f) = \langle f, (-L_1^+ f) \rangle_{\mu_{\rho}^{\Lambda_2^*}},$$

$$D_0(\mu_{\rho}^{\Lambda_0^*}, f) = \langle f, (-L_0^2 f) \rangle_{\mu_{\rho}^{\Lambda_0^*}}.$$  \hspace{1cm} (5.3)

A simple computation shows that the Dirichlet form can be written as

$$D_{\Lambda_1^*}(\mu_{\rho}^{\Lambda_1^*}, f) = \frac{\varphi(\rho)}{2} \sum_{x=-2(l+1)}^{2} \int \{ f(\eta + \delta_{x+1}, \zeta) - f(\eta + \delta_{x}, \zeta) \}^2 \mu_{\rho}^{\Lambda_1^*}(d\eta, d\zeta),$$

$$D_0(\mu_{\rho}^{\Lambda_0^*}, f) = \frac{\varphi(\rho)}{2} \int \{ f(\eta + \delta_{-1}, \zeta) - f(\eta, \zeta + \delta_1) \}^2 \mu_{\rho}^{\Lambda_0^*}(d\eta, d\zeta).$$

In this notation, it will be enough, with respect to equation (5.2), to bound for $a > 0$ the quantity

$$\sup_f \left\{ \left\langle [H(\eta') - H(\zeta')] \mathbf{1}\{G'_N,l\}, f^2 \right\rangle_{\mu_{\rho}} - a \langle f, (-L_{N,l\epsilon} f) \rangle_{\mu_{\rho}} \right\},$$

where $\eta' = (2l+1)^{-1} \sum_{x \in \Lambda_1^*} \eta(x)$, $\zeta' = (2l+1)^{-1} \sum_{x \in \Lambda_2^*} \zeta(x)$, and $G'_N,l = \{ (\eta, \zeta) : \eta' + \zeta' \leq 2C_1 \log N \}$. By convexity of the Dirichlet form, as in the proof of Lemma 4.1, the supremum may be taken over functions $f$ on $N_0^{\Lambda_1^*}$ such that $\langle f^2 \rangle_{\mu_{\rho}^{\Lambda_1^*}} = 1$, and the measure $\mu_{\rho}$ in (5.3) may be replaced by $\mu_{\rho}^{\Lambda_1^*}$.  

**Step 6.** This quantity is estimated in three parts. The first part restricts to the set $S_{N,l} = \{ (\eta, \zeta) : \eta' + \zeta' \leq B \}$ for some $B$ fixed. In this case, where we have truncated at a fixed level $B$, we can use the “local 1-block” method of Lemma 4.1 to show that

$$\sup_f \left\{ \left\langle [H(\eta') - H(\zeta')] \mathbf{1}\{S_{N,l}\}, f^2 \right\rangle_{\mu_{\rho}^{\Lambda_1^*}} - a \langle f, (-L_{N,l\epsilon} f) \rangle_{\mu_{\rho}^{\Lambda_1^*}} \right\}$$

vanishes as $N \uparrow \infty$, $\epsilon \downarrow 0$ and then $l \uparrow \infty$.

Indeed, by convexity considerations, we can decompose the expression in braces in terms of canonical measures $\mu_{\Lambda_1^*,k}$ concentrating on $k$ particles in $\Lambda_1^*$. Since for the generator $L_{N,l\epsilon} j$ jumps are speeded up by $N$ inside each cube,

$$\langle [H(\eta') - H(\zeta')] \mathbf{1}\{S_{N,l}\}, f^2 \rangle_{\mu_{\rho}^{\Lambda_1^*},k} - a \langle f, (-L_{N,l\epsilon} f) \rangle_{\mu_{\Lambda_1^*,k}}$$

$$\leq \langle [H(\eta') - H(\zeta')] \mathbf{1}\{S_{N,l}\}, f^2 \rangle_{\mu_{\rho}^{\Lambda_1^*},k} - a \epsilon^{-1} \langle f, -(L_1^- + L_1^+ + L_0^2 f) \rangle_{\mu_{\Lambda_1^*,k}}$$

Let $\tilde{V}_l = [H(\eta') - H(\zeta')] \mathbf{1}\{S_{N,l}\}$. Note that $\tilde{V}_l$ has mean-zero with respect to $\mu_{\Lambda_1^*,k}$ and that $\|\tilde{V}_l\|_{L^\infty} \leq 2\|H\|_{L^\infty}$. By the Rayleigh estimate [27, Theorem A3.1.1] and by the spectral gap, for $k \leq 2(2l+1)B$, the previous expression is bounded above by

$$\frac{a^{-1}\epsilon}{1-4\|H\|_{L^\infty} W^*(l, k) a^{-1}\epsilon} \int \tilde{V}_l (-L_1^- - L_1^+ - L_0^2) \tilde{V}_l d\mu_{\Lambda_1^*,k}$$

$$\leq 2a^{-1}\epsilon W^*(l, k) \int \tilde{V}_l^2 d\mu_{\Lambda_1^*,k},$$

where $W^*(l, k)$ is the inverse of the spectral gap of $L^- + L^+ + L_0^2$ with respect to the process on $\Lambda_1^*$ with $k$ particles. As $\epsilon \downarrow 0$, the previous expression vanishes.
Step 7. The second part now restricts to \( S_{N,t}^2 = \{(\eta, \zeta) : \zeta^l \geq A, \eta^l \geq A\} \) for some constant \( A \). On this event, the sum \( H(\eta^l) + H(\zeta^l) \) is absolutely bounded by \( 2 \sup_{z \geq A} |H(z)| \) so that

\[
\left( \left[ H(\eta^l) - H(\zeta^l) \right] \mathbf{1}\{S_{N,t}^2\}, f^2 \right)_{\mu^N_{\rho}} - a(f, (-L_{N,t} f))_{\mu^N_{\rho}} \leq 2 \sup_{z \geq A} |H(z)| .
\]

Since \( H(n) \) vanishes as \( n \uparrow \infty \), the right hand side can be made arbitrarily small.

Step 8. Let now \( S_{N,t}^3 = A_t \cap R_{N,t} \) where \( A_t = \{ \eta : \eta^l \leq A \} \) and \( R_{N,t} = \{(\eta, \zeta) : B \leq \eta^l + \zeta^l \leq 2C_1 \log N\} \). This case is the difficult part of the proof and is treated in Lemma 5.2 below.

The proof of Lemma 5.2 is reserved to the next subsection.

**Lemma 5.2.** Suppose that \( B > 4A \). Then, for every \( a > 0 \),

\[
\lim_{l \to \infty} \limsup_{\varepsilon \to 0} \sup_{N \to \infty} \sup_f \left\{ \int \mathbf{1}\{R_{N,t}\} \right\} \left\{ A_t \right\} f(\eta, \zeta) d\mu^N_{\rho} - a(f, (-L_{N,t} f))_{\mu^N_{\rho}} \right\} \leq 0 ,
\]

where the supremum over \( f \) is over functions \( f : \mathbb{N}_0^N \) such that \( (f, f)_{\mu^N_{\rho}} = 1 \).

**Lemma 5.3.** For \( s, r \geq 0 \), we have \( \mu_{A_s, r} \ll \mu_{A_{s+1}, r} \), and \( \nu_{A_s, r} \ll \nu_{A_{s+1}, r} \).

**Proof.** The first estimate is [10] Lemma 4.4]. The second bound has a similar argument: Note \( \nu_{A_s, r} \) is the unique invariant measure for the Markov chain on \( \Sigma_{A_s, r}^* = \{ \eta : \eta(0) \geq 1, \sum_{|x| \leq s} \eta(x) = r \} \) generated by \( L^uv_{A_s} \).

Since \( g \) is increasing, we can couple two systems starting from configurations \( \eta^1 \in \Sigma_{A_s, r} \) and \( \eta^2 \in \Sigma_{A_{s+1}, r} \) such that \( \eta^1 \leq \eta^2 \) coordinatewise, so that the ordering is preserved at later times. Hence, in the limit we obtain \( \lim_{l \uparrow \infty} \eta^1_l = \nu_{A_s, r} \), \( \lim_{l \uparrow \infty} \eta^2_l = \nu_{A_{s+1}, r} \), and \( \nu_{A_s, r} \ll \nu_{A_{s+1}, r} \).

Recall the set \( \hat{A}_t = \{-l, \ldots, 3l + 1\} \).

**Lemma 5.4.** Let \( H : \mathbb{R}^d \to \mathbb{R} \) be a positive, bounded, Lipschitz function which vanishes at infinity. Then, we have

\[
\lim_{l \to \infty} \sup_{k \geq 0} \sup_{\eta^l \in \hat{A}_t} \left| E_{\nu_{A,s,k}} \left[ H(\eta^l(0)) - H(\eta^l(2l)) \right] \right| = 0 .
\]

**Proof.** The argument is in three parts.

Step 1. Fix \( \epsilon > 0 \) and consider \( (k, l) \) such that \( k/|\hat{A}_t| \leq \epsilon \). Add and subtract \( H(0) \) in the absolute value. Then, the expectation is less than \( 2 \max_{0 \leq x \leq 2l} |H(x) - H(0)| = O(\epsilon) \) given that \( H \) is Lipschitz.

Step 2. Assume now that \( \epsilon \leq k/|\hat{A}_t| \leq 2 \). The proof is the same as in Lemma 6.6 in [10] for this case. For the convenience of the reader, we give it here. By definition of \( \nu_{A,s,k} \), the expectation appearing in the display of the lemma equals

\[
\frac{1}{E_{\rho_{A,s,k}}(\eta(0))} E_{\nu_{A,s,k}} \left[ \eta(0) \left\{ H(\eta^l(0)) - H(\eta^l(2l)) \right\} \right] .
\]

Since the measure is space homogeneous, the denominator is equal to \( \rho_{l,k} = k/|\hat{A}_t| \) which is bounded below by \( \epsilon \). In the numerator, \( \eta(0) \) can be replaced by \( \eta^l(0) \). The
numerator is then
\[ E_{\mu_{\Lambda,l,k}} \left[ \{ \eta'(0) - \rho_{l,k} \} \{ H(\eta'(0)) - H(\eta'(2l + 1)) \} \right] \]
\[ + \rho_{l,k} E_{\mu_{\Lambda,l,k}} \left[ H(\eta'(0)) - H(\eta'(2l + 1)) \right]. \]

The second term vanishes because the measure \( \mu_{\Lambda,l,k} \) is space homogeneous. The first term, as \( H \) is bounded, is absolutely dominated by \( 2\|H\|_{L^\infty} E_{\mu_{\Lambda,l,k}} |\eta'(0) - \rho_{l,k}| \). By [7, Appendix II.1 Corollary 1.4], this expression is less than or equal to
\[ C_0 E_{\mu_{\Lambda,l,k}} \left[ |\eta'(0) - \rho_{l,k}| \right] \leq C_0 \sigma(\rho_{l,k}) l^{-1/2}, \]
for some constant \( C_0 \) where \( \sigma(\rho) \) stands for the variance of \( \xi(0) \) under \( \mu_\rho \). Since \( \epsilon \leq \rho_{l,k} \leq B_1 \), \( \sigma(\rho_{l,k}) \) is bounded. Hence, this expression vanishes as \( l \uparrow \infty \).

Step 3. Suppose now \( k/|\Lambda_l| \geq B_1 \). We shall prove that in this range both expectations are small because \( H(x) \) vanishes as \( x \uparrow \infty \). Fix \( A > 0 \). Introducing the indicator of the set \( |\eta'(0)| \leq A \) and replacing the Palm measure \( \nu_{\Lambda,l,k} \) by the homogeneous measure \( \mu_{\Lambda,l,k} \), we get that
\[ E_{\nu_{\Lambda,l,k}} [H(\eta'(0))] \leq E_{\nu_{\Lambda,l,k}} [H(\eta'(0)) \mathbb{1}\{ |\eta'(0)| \leq A \}] + \sup_{x \geq A} H(x) \]
\[ = \frac{1}{\rho_{l,k}} E_{\mu_{\Lambda,l,k}} [\eta(0) H(\eta'(0)) \mathbb{1}\{ |\eta'(0)| \leq A \}] + \sup_{x \geq A} H(x) \]
because \( E_{\mu_{\Lambda,l,k}} [\eta(0)] = \rho_{l,k} \). In the last expectation, we may replace \( \eta(0) \) by \( \eta'(0) \) which is bounded by \( A \). We may also estimate \( H \) by \( \|H\|_{L^\infty} \) and bound below the density \( \rho_{l,k} \) by \( B_1 \). The previous expression is thus less than or equal to
\[ \frac{A\|H\|_{L^\infty}}{B_1} + \sup_{x \geq A} H(x), \]
which can be made arbitrarily small if \( A \) is chosen large enough and then \( B_1 \).

It remains to prove that the second expectation appearing in the statement of the lemma is small in this range of densities. Introducing the indicator of the set \( \{ \eta'(2l + 1) \leq A \} \) we get that
\[ E_{\nu_{\Lambda,l,k}} [H(\eta'(2l + 1))] \leq \|H\|_{L^\infty} \nu_{\Lambda,l,k} \{ \eta'(2l + 1) \leq A \} + \sup_{x \geq A} H(x). \]

Since the event \( \{ \eta'(2l + 1) \leq A \} \) is decreasing and \( k \geq B_1 |\Lambda_l| \), by Lemma [5,4] we may bound the previous probability by \( \nu_{\Lambda,l,K} \{ \eta'(2l + 1) \leq A \} \), where \( K = B_1 |\Lambda_l| \).

At this point, by the same reasons argued above, we obtain that
\[ E_{\nu_{\Lambda,l,k}} [H(\eta'(2l + 1))] \leq \frac{\|H\|_{L^\infty}}{B_1} E_{\mu_{\Lambda,l,k}} [\eta'(0) \mathbb{1}\{ |\eta'(0)| \leq A \}] + \sup_{x \geq A} H(x). \]

Note that \( \eta'(0) \leq B_1 |\Lambda_l|/(2l + 1) = 2B_1 \). Hence, by [7, Corollary 1.4, Appendix 2.1], the previous expectation is bounded by
\[ 2\|H\|_{L^\infty} \mu_{B_1} \{ \eta'(2l + 1) \leq A \} + \frac{C_0}{l}, \]
for some finite constant \( C_0 \). This expression vanishes as \( l \uparrow \infty \) by the law of large numbers provided \( B_1 > A \). This concludes the proof of the lemma. □
5.1. Proof of Lemma \[5.2\] Fix $B > 4A$. The proof is divided in three steps. Recall the notation developed in Step 5 of the proof of Lemma \[5.1\]

**Step 1.** The first integral in \[5.3\] can be rewritten as

$$
\sum_{j,k} \mu_{\rho,l}(j) \mu_{\rho,l}(k) \int \int f(\eta,\zeta)^2 \mu_{\Lambda^+_l,j}(d\eta) \mu_{\Lambda^+_l,k}(d\zeta),
$$

where the sum is performed over all indices $j$, $k$ such that $0 \leq j \leq A(2l+1)$, $k \geq 0$, $B(2l+1) \leq j + k \leq \theta_N$, $\mu_{\rho,l}(m) = \mu_\rho(\sum_{x \in \Lambda l} \eta(x) = m)$ and $\mu_{\Lambda^+_l,m}$ is the canonical measure on the cube $\Lambda^+_l$ concentrated on configurations with $m$ particles.

Fix two integers $j, k \geq 0$ such that $B(2l+1) \leq j + k \leq \theta_N$. We claim that there exists a function $W_N(l)$ such that $W_N(l) = o(N)$ for fixed $l$ and

$$
\int \int f(\eta,\zeta)^2 \mu_{\Lambda_l^-,j}(d\eta) \mu_{\Lambda_l^+,k}(d\zeta) - \left\{ \int \int f(\eta,\zeta) \mu_{\Lambda_l^-,j}(d\eta) \mu_{\Lambda_l^+,k}(d\zeta) \right\}^2
\leq W_N(l) \left\{ D_{\Lambda_l^-}(\mu_{\Lambda_l^+,j,k},f) + D_{\Lambda_l^+}(\mu_{\Lambda_l^-,j,k},f) \right\},
$$

(5.6)

where $\mu_{\Lambda_l^-,j,k}$ represents the measure $\mu_{\Lambda_l^-,j} \mu_{\Lambda_l^+,k}$ and $D_{\Lambda_l^+}(\mu_{\Lambda_l^+,j,k},f)$ is the Dirichlet form defined in \[5.3\] with the canonical measure $\mu_{\Lambda_l^+,j,k}$ in place of the grand canonical measure $\mu_{\beta l}^\star$.

To prove claim \[5.6\], recall $W(l,j)$ is the inverse of the spectral gap of the generator of the zero range process in which $j$ particles move on a cube of length $2l + 1$. By definition of $W(l,j)$, for each configuration $\zeta$,

$$
\int f(\eta,\zeta)^2 \mu_{\Lambda_l^-,j}(d\eta) - \left\{ \int f(\eta,\zeta) \mu_{\Lambda_l^-,j}(d\eta) \right\}^2
\leq W(l,j) \sum_{x=-l}^{l-1} \int \left\{ f(\eta^{x+1},\zeta) - f(\eta,\zeta) \right\}^2 \mu_{\Lambda_l^-,j}(d\eta).
$$

Integrating with respect to $\mu_{\Lambda_l^+,k}(d\zeta)$ we get that

$$
\int \mu_{\Lambda_l^+,k}(d\zeta) \int f(\eta,\zeta)^2 \mu_{\Lambda_l^-,j}(d\eta)
\leq \int \mu_{\Lambda_l^+,k}(d\zeta) \left\{ \int f(\eta,\zeta) \mu_{\Lambda_l^-,j}(d\eta) \right\}^2 + W(l,j) D_{\Lambda_l^-}(\mu_{\Lambda_l^+,j,k},f).
$$

Let

$$
h(\zeta) = \int f(\eta,\zeta) \mu_{\Lambda_l^-,j}(d\eta).
$$

By definition of the spectral gap,

$$
\int h(\zeta)^2 \mu_{\Lambda_l^+,k}(d\zeta) - \left\{ \int h(\zeta) \mu_{\Lambda_l^+,k}(d\zeta) \right\}^2 \leq W(l,k) D_{\Lambda_l^+}(\mu_{\Lambda_l^+,k},h).
$$

By Schwarz inequality

$$
D_{\Lambda_l^+}(\mu_{\Lambda_l^+,k},h) \leq D_{\Lambda_l^+}(\mu_{\Lambda_l^-,j,k},f).
$$

This proves \[5.6\], applying the estimate on the spectral gap in Lemma \[2.2\] when $g$ satisfies (B), or by assumption when $g$ satisfies (SL).
Multiplying both sides of (5.3) by \( \mu_{p,l}(j) \mu_{p,l}(k) \) and summing over \( j \) and \( k \) such that \( 0 \leq j \leq A(2l + 1), k \geq 0, B(2l + 1) \leq j + k \leq \theta_{N,l} \), we see that to prove the lemma it is enough to show that for every \( a > 0 \)

\[
\sum_{j,k} \mu_{p,l}(j) \mu_{p,l}(k) \left\{ \int f(\eta, \zeta) \mu_{\Lambda_j^-}(d\eta) \mu_{\Lambda_k^+}(d\zeta) \right\}^2 - a \left\langle f, (-L_{N,l}(f)) \right\rangle_{\mu_{\Lambda_j^-}} \tag{5.7}
\]

vanishes as \( N \uparrow \infty, \varepsilon \downarrow 0, l \uparrow \infty \).

Step 2. To estimate (5.7), let

\[
F(j, k) = \int \int f(\eta, \zeta) \mu_{\Lambda_j^-}(d\eta) \mu_{\Lambda_k^+}(d\zeta).
\]

We now claim there exists \( W_N(l) \), where \( W_N(l) = o(N) \) for fixed \( l \), and a finite constant \( C_0 \) such that

\[
\sum_{j,k} \mu_{p,l}(j) \mu_{p,l}(k) [F(j + 1, k - 1) - F(j, k)]^2 \leq W_N(l) \left\{ D_{\Lambda_j^+}(\mu_{\rho}^{\Lambda_j^+}, f) + D_{\Lambda_k^+}(\mu_{\rho}^{\Lambda_k^+}, f) \right\} + C_0 l^5 D_0(\mu_{\rho}^{\Lambda_j^+}, f), \tag{5.8}
\]

where the sum is over all \( j \) and \( k \) such that \( j \geq 0, k \geq 1, B(2l + 1) \leq j + k \leq \theta_{N,l} \).

To prove (5.8), note that since \( \mu_{\Lambda_j^-}(d\eta) \) is the canonical measure,

\[
F(j + 1, k - 1) = \int \mu_{\Lambda_j^+}(d\zeta) \int f(\eta, \zeta) \frac{1}{j + 1} \sum_{x \in \Lambda_j^+} \eta(x) \mu_{\Lambda_j^-}(d\eta).
\]

Changing variables \( \eta' = \eta - \vartheta_x \), the previous expression becomes

\[
\frac{1}{2l + 1} \sum_{x \in \Lambda_j^+} \int \mu_{\Lambda_j^+}(d\zeta) \int f(\eta + \vartheta_x, \zeta) h_{l,j}(\eta(x)) \mu_{\Lambda_j^-}(d\eta),
\]

where

\[
h_{l,j}(\eta(x)) = \frac{2l + 1}{j + 1} \frac{\varphi(\rho) \mu_{p,l}(j) \cdot 1 + \eta(x)}{g(1 + \eta(x))}.
\]

Note that \( h_{l,j}(\eta(x)) \) has mean equal to 1 with respect to \( \mu_{\Lambda_j^-}(d\eta) \).

Changing variables \( \zeta' = \zeta + \vartheta_y \), the previous integral becomes

\[
\frac{1}{(2l + 1)^2} \sum_{x \in \Lambda_j^+} \sum_{y \in \Lambda_j^+} \int \mu_{\Lambda_j^+}(d\zeta) \int f(\eta + \vartheta_x, \zeta - \vartheta_y) h_{l,j}(\eta(x)) e_{l,k}(\zeta(y)) \mu_{\Lambda_j^-}(d\eta),
\]

where

\[
e_{l,k}(\zeta(y)) = \frac{\mu_{p,l}(k) \cdot g(\zeta(y))}{\mu_{p,l}(k - 1) \cdot \varphi(\rho)}
\]

has mean 1 with respect to \( \mu_{\Lambda_j^+} \).
This identity permits to write $F(j + 1, k - 1) - F(j, k)$ as the sum of two terms

$$
\frac{1}{(2l + 1)^2} \sum_{x \in \Lambda^+} \int \mu_{\Lambda^+,k}(d\zeta) \int \left\{ f(\eta + \partial_x, \zeta - \partial_y) - f(\eta, \zeta) \right\} 
\cdot h_{l,j}(\eta(x)) e_{l,k}(\zeta(y)) \mu_{\Lambda^+,j}(d\eta)
+ \int \mu_{\Lambda^+,k}(d\zeta) \int f(\eta, \zeta) \frac{1}{(2l + 1)^2} \sum_{x \in \Lambda^+} [h_{l,j}(\eta(x)) e_{l,k}(\zeta(y)) - 1] \mu_{\Lambda^+,j}(d\eta) .
$$

(5.9)

Since $(a + b)^2 \leq 2a^2 + 2b^2$, $[F(j + 1, k - 1) - F(j, k)]^2$ is bounded above by the sum of two terms. One term, corresponding to the last line of (5.9), is equal to

$$
2 \left( \left\langle f ; \frac{1}{(2l + 1)^2} \sum_{x \in \Lambda^+} h_{l,j}(\eta(x)) e_{l,k}(\zeta(y)) \right\rangle_{l,j,k} \right)^2 ,
$$

(5.10)

where $\langle F; G \rangle_{l,j,k}$ denotes the covariance of $F$ and $G$ with respect to $\mu_{\Lambda^+,k} \mu_{\Lambda^+,j}$.

Since

$$
\frac{\varphi(\rho) \mu_{\rho,l}(r)}{\mu_{\rho,l}(r + 1)} = E_{\mu_{\Lambda^+,r+1}}[g(\eta(1))] ,
$$

(5.11)

we have that

$$
h_{l,j}(\eta(x)) e_{l,k}(\zeta(y)) = \frac{2l + 1}{j + 1} \frac{\varphi(\rho) \mu_{\rho,l}(j) 1 + \eta(x) \mu_{\rho,l}(k) g(\zeta(y))}{\mu_{\rho,l}(j + 1) g(1 + \eta(x)) \mu_{\rho,l}(k - 1) \varphi(\rho)}
= \frac{2l + 1}{j + 1} \frac{1 + \eta(x)}{g(1 + \eta(x))} \frac{g(\zeta(y)) E_{\mu_{\Lambda^+,j+1}}[g(\eta(-1))]}{E_{\mu_{\Lambda^+,l,k}}[g(\zeta(1))]}. 
$$

We claim that under the measure $\mu_{\Lambda^+,k} \mu_{\Lambda^+,j}$,

$$
h_{l,j}(\eta(x)) e_{l,k}(\zeta(y)) \leq C_0 l \frac{g(\zeta(y))}{E_{\mu_{\Lambda^+,k+k}}[g(\zeta(1))]}
$$

(5.12)

for some finite constant $C_0$ depending only on $a_0$, $a_1$. This bound is simple to derive when $g$ fulfills assumption (B). On the other hand, under the assumptions (SL), since $g$ is increasing, $E_{\mu_{\Lambda^+,j+1}}[g(\eta(-1))] \leq g(j + 1)$, and since $g(k)/k$ is decreasing, under the measure $\mu_{\Lambda^+,j}$, $[1 + \eta(x)]/g(1 + \eta(x))$ is less than or equal to $(j + 1)/g(j + 1)$. This proves (5.12). This is the only place where we use that $g(k)/k$ is decreasing in $k$ in the condition (SL).

Therefore, by Schwarz inequality, (5.10) is bounded above by

$$
C_0 l \langle f ; f \rangle_{l,j,k} \sum_{y \in \Lambda^+} \frac{E_{\mu_{\Lambda^+,k}}[g(\zeta(1))]^2}{E_{\mu_{\Lambda^+,k+k}}[g(\zeta(1))]^2} 
$$
for some finite constant $C_0$. In view of (5.11), the fact that $g(m+1) - g(m) \leq a_2$, which follows from assumption (B) or from assumption (SL2), and Lemma 5.3,

\[
E_{\mu_{\lambda_+^j,k}}[g(\zeta(y))^2] = E_{\mu_{\lambda_+^j,k}}[g(\zeta(y))] E_{\mu_{\lambda_+^j,k}}[g(\zeta(y) + 1)] \\
\leq E_{\mu_{\lambda_+^j,k}}[g(\zeta(y))] \left\{ a_2 + E_{\mu_{\lambda_+^j,k}}[g(\zeta(y))] \right\} \\
\leq E_{\mu_{\lambda_+^j,k}}[g(\zeta(y))] \left\{ a_2 + E_{\mu_{\lambda_+^j,k}}[g(\zeta(y))] \right\}.
\]

As $g$ is increasing, by Lemma 5.3, $E_{\mu_{\lambda_+^j,k}}[g(\zeta(1))] \leq E_{\mu_{\lambda_+^j,k}}[g(\zeta(1))]$. Hence, since $a_0 1 \{ r \geq 1 \} \leq g(r)$, and since $E_{\mu_{\lambda_+^j,k}}[1 \{ \zeta(1) \geq 1 \}] = E_{\mu_{\lambda_+^j,k}}[\zeta(1)] = (2l+1)^{-1}$, we have that

\[
\frac{a_0}{2l+1} = a_0 E_{\mu_{\lambda_+^j,k}}[1 \{ \zeta(1) \geq 1 \}] \leq E_{\mu_{\lambda_+^j,k}}[g(\zeta(1))].
\]

It follows from this estimate and from the previous bound that (5.10) is less than or equal to

\[
C_0 t^3 (f : f)_{l,j,k}.
\]

Multiply this expression by $\mu_{\rho,l}(j) \mu_{\rho,l}(k)$, recall the bound (5.6), and sum over $j$ and $k$ such that $j \geq 0$, $k \geq 1$, $B(2l+1) \leq j + k \leq \theta_N$, to get that (5.10) is bounded by

\[
W_N(l) \left\{ D_{\lambda_-^j}(\mu_{\rho,1}^j, f) + D_{\lambda_-^j}(\mu_{\rho,1}^{j+1}, f) \right\},
\]

where $W_N(l) = o(N)$ for fixed $l$.

We now estimate the first term in the decomposition (5.9). By Schwarz inequality and by the bounds (5.12), (5.13), the square of this expression is less than or equal to

\[
C_0 t^3 \sum_{x \in \Lambda_t^-} \int_{y \in \Lambda_t^-} \mu_{\lambda_-^j,k}(d\zeta) \int g(\zeta(y)) \{ f(\eta + \delta x, \zeta - \delta y) - f(\eta, \zeta) \}^2 \mu_{\lambda_-^j}(d\eta)
\]

for some finite constant $C_0$. The sum over $j \geq 0$, $k \geq 1$ of this expression, when multiplied by $\mu_{\rho,l}(k) \mu_{\rho,l}(j)$, is bounded by

\[
C_0 t^3 \sum_{x \in \Lambda_t^-} \int_{y \in \Lambda_t^-} \mu_{\lambda_-^j \rho}(d\zeta) \int g(\zeta(y)) \{ f(\eta + \delta x, \zeta - \delta y) - f(\eta, \zeta) \}^2 \mu_{\lambda_-^j \rho}(d\eta).
\]

Changing variables $\zeta' = \zeta - \delta y$, adding and subtracting in the expression inside braces the terms $f(\eta + \delta x, \zeta)$, $f(\eta, \zeta + \delta y)$, we estimate the previous expression by

\[
C_0 t^5 D_0(\mu_{\lambda_-^j \rho}, f) + C_0 t^5 \left\{ D_{\lambda_-^j}(\mu_{\lambda_-^j \rho}, f) + D_{\lambda_-^j}(\mu_{\lambda_-^j \rho}, f) \right\}
\]

for some constant $C_0$. This proves claim (5.8).

**Step 3.** In view of (5.7) and of (5.8), to prove the lemma it is enough to show that for every $a > 0$

\[
\lim_{l \to \infty} \limsup_{\varepsilon \to 0} \sup_{F} \left\{ \sum_{j,k} F(j,k)^2 \mu_{\rho,l}(j) \mu_{\rho,l}(k) \\
- a \varepsilon^{-1} \sum_{j,k} \{ F(j+1, k-1) - F(j,k) \}^2 \mu_{\rho,l}(j) \mu_{\rho,l}(k) \right\} = 0,
\]
where the first sum is carried over all $0 \leq j \leq A(2l+1), k \geq 0, B(2l+1) \leq j+k \leq \theta_{N,l}$, the second sum is carried over all $j \geq 0, k \geq 1, B(2l+1) \leq j+k \leq \theta_{N,l}$ and where the supremum is carried over all functions $F : \mathbb{N}_0 \times \mathbb{N}_0 \to \mathbb{R}$ such that

$$\sum_{j,k \geq 0} F(j,k)^2 \mu_{p,l}(j) \mu_{p,l}(k) = 1.$$ 

The expression inside braces can be bounded by

$$\sum_{M=B(2l+1)}^{\theta_{N,l}} \mu_{p,\Lambda_l^-}(M) Z_M(F) \left\{ \sum_{j=0}^{A(2l+1)} \frac{G(j)^2 \mu_{\Lambda_l^+}.M(j)}{\mu_{p,\Lambda_l^-}(M)} \right\},$$

where

$$\mu_{p,\Lambda_l^-}(M) = \sum_{j=0}^{B(2l+1)} \mu_{p,l}(j) \mu_{p,l}(M-j), \quad \mu_{\Lambda_l^+}.M(j) = \frac{\mu_{p,l}(j) \mu_{p,l}(M-j)}{\mu_{p,\Lambda_l^-}(M)},$$

$$Z_M(F) = \sum_{j=0}^{B(2l+1)} F(j,M-j)^2 \mu_{\Lambda_l^+}.M(j), \quad Z_M(F) G(j)^2 = F(j,M-j)^2.$$ 

Note that we omitted the dependence on $B$ of the variables $\mu_{p,\Lambda_l^-}(M)$, $\mu_{\Lambda_l^+}.M(j)$, $Z_M(F)$ and that $\sum_{0 \leq j \leq B(2l+1)} G(j)^2 \mu_{\Lambda_l^+}.M(j) = 1$.

The expression inside braces in (5.14) can be interpreted in terms of a random walk on an interval of length $B(2l+1)$ where the total number of particles $M$ becomes a parameter. In fact, the second term in braces corresponds to the Dirichlet form of a random walk on $\{0, \cdots, B(2l+1)\}$ which jumps from $j$ to $j+1$, $0 \leq j \leq B(2l+1)-1$, at rate 1 and from $j+1$ to $j$ at rate $r_M(j+1,j) = \mu_{\Lambda_l^+}.M(j)/\mu_{\Lambda_l^-}.M(j+1)$. By (5.11),

$$r_M(j+1,j) = \frac{\mu_{p,l}(j)}{\mu_{p,l}(M-j)} \frac{\mu_{p,l}(M-j)}{\mu_{p,l}(M-j-1)} = \frac{E_{\mu_{\Lambda_l^+}.j,1}^+ \{ g(\eta(1)) \}}{E_{\mu_{\Lambda_l^-}.M,j} \{ g(\eta(1)) \}}.$$ 

We claim that this random walk has a spectral gap

$$\lambda_{\Lambda,l}$$ which depends on $B$ and $l$ but is uniform over $M$. (5.15)

Assume first that $g$ satisfies (B). In this case, by (5.13), the previous ratio is bounded above by $a_1 a_0^{-1}(2l+1)$ and below by $a_0 a_1^{-1}(2l+1)^{-1}$. The jump rates are therefore bounded below and above by finite constants independent of $M$, and claim (5.15) follows easily.

Assume now that $g$ satisfies (SL). We claim that for $l$ large enough,

$$\lim_{M \to \infty} \max_{0 \leq j \leq B(2l+1)-1} r_M(j+1,j) = 0.$$ (5.16)

Indeed, by Lemma 5.3, $E_{\mu_{\Lambda_l^+}.j,1}^+ \{ g(\eta(1)) \} \leq g(B(2l+1))$. On the other hand, for every $D \leq D'(2l+1) \leq M-B(2l+1) \leq M-j$

$$E_{\mu_{\Lambda_l^+}.M-j} \{ g(\eta(1)) \} \geq E_{\mu_{\Lambda_l^+}.M-j} \{ g(\eta(1)) \} 1 \{ \eta(1) \geq D \} \geq g(D) \mu_{\Lambda_l^+}.D'(2l+1) \{ \eta(1) \geq D \} \geq g(D) \{ \mu_{\Lambda_l^+}.\eta(1) \geq D \} - C_0/l ,$$

where the last inequality follows from the equivalence of ensembles [7, Appendix 2.1, Corollary 1.7] and $C_0$ is a finite constant. The right-side can be made arbitrarily
large since \( \lim_{D \uparrow \infty} \mu_D \{ \eta(1) \geq D \} = 1 \) and \( \lim_{D \uparrow \infty} g(D) = \infty \). This proves claim (5.16).

Fix \( M_0 \) and \( l \) large enough so that \( r_M(j+1, j) < 1 \) for all \( 0 \leq j \leq B(2l+1) - 1 = Q, M \geq M_0 \). The stationary probabilities for the corresponding birth-death chain on the interval can be expressed as

\[
\pi_j = \frac{\left( \prod_{s=0}^{j-1} r_M(s + 1, s) \right)^{-1}}{1 + \sum_{t=1}^{Q} \left( \prod_{s=0}^{t-1} r_M(s + 1, s) \right)^{-1}},
\]

where the empty product in the numerator is taken to be 1 when \( j = 0 \). We note by construction that \( \pi_{j} \leq \pi_{j+1} \). We have the Poincaré inequality:

\[
\mathrm{Var}_{\pi}(f) \leq \sum_{x,y} \pi_x \pi_y (f(x) - f(y))^2 \leq 2Q \sum_{y>x}^{y-1} \pi_x \pi_y \sum_{z=x}^{y-1} (f(z) - f(z+1))^2 \leq 2Q \sum_{y>x}^{y-1} \pi_y \sum_{z=x}^{y-1} (f(z) - f(z+1))^2 \leq 2Q \sum_{z=0}^{Q-1} \pi_z (f(z) - f(z+1))^2.
\]

Hence, for large \( M \), the inverse of the spectral gap, \( \lambda^{-1}_{l,B} \), is bounded by \( C_0 l^2 \) for some constant \( C_0 \) depending only on \( B \). For \( M \leq M_0 \), recalling (5.12), we may obtain a lower and an upper bound on \( r_M(j+1, j) \) which depend only on \( a_0, a_1, a_2, B, l \) and \( M_0 \). It is easy to show that in this case the inverse gap, \( \lambda^{-1}_{l,B} \), is bounded by a constant which depends only on \( B, l \) and \( M_0 \). This concludes the proof of claim (5.15).

At this point, we may apply the Rayleigh bound [7, Theorem A3.1.1] to estimate the expression in braces in (5.14). Let \( V_0 = 1 \{0, \ldots, A(2l + 1)\} \) and let \( \tilde{V}_0 = V_0 - \mathcal{E}_{\mu_{\Lambda^*_l,M}}[V_0] \) so that

\[
A(2l+1) \sum_{j=0}^{B(2l+1)} G(j)^2 \mu_{\Lambda^*_l,M}(j) = \sum_{j=0}^{B(2l+1)} V_0(j) G(j)^2 \mu_{\Lambda^*_l,M}(j).
\]

Since \( \|V_0\|_{L^\infty} \leq 1 \), by the Rayleigh expansion and by the spectral gap, the display in braces in (5.14) is bounded by

\[
\frac{A(2l+1)}{A(2l+1)} \sum_{j=0}^{A(2l+1)} \mu_{\Lambda^*_l,M}(j) + \frac{a^{-1} \varepsilon^{\lambda^{-1}_{l,B}}}{1 - 2 a^{-1} \varepsilon^{\lambda^{-1}_{l,B}}},
\]

The second term vanishes as \( \varepsilon \downarrow 0 \). To bound the first term, let \( \alpha_j = \mu_{\rho,l}(j) \mu_{\rho,l}(M-j) \), \( 0 \leq j \leq M \). Since \( B > 2A \), the first term in the last formula is equal to

\[
\frac{\sum_{j=0}^{A(2l+1)} \alpha_j}{\sum_{j=0}^{B(2l+1)} \alpha_j} \leq \frac{\sum_{j=0}^{A(2l+1)} \alpha_j}{\sum_{j=A(2l+1)}^{A(2l+1)} \alpha_j} \leq \max_{0 \leq j \leq A(2l+1)} \frac{\alpha_j}{\alpha_j + A(2l+1)}.
\]

As above in calculating \( r_M(j+1, j) \), since \( g \) is increasing and \( M \geq B(2l+1) \), if \( R = A(2l + 1), \ S = (B - 2A)(2l + 1) \), by Lemma 5.3,

\[
\frac{\alpha_j}{\alpha_{j+R}} = \prod_{k=j}^{j+R-1} \frac{E_{\mu_{\Lambda^*_l,k+1}^+[g(\eta(1))]}[g(\eta(1))]}{E_{\mu_{\Lambda^*_l,k+1}^+[g(\eta(1))]}[g(\eta(1))]} \leq \left\{ \frac{E_{\mu_{\Lambda^*_l,R}^+[g(\eta(1))]}[g(\eta(1))]}{E_{\mu_{\Lambda^*_l,S}^+[g(\eta(1))]}[g(\eta(1))]} \right\}^R.
\]
Since $B > 4A$, by [7] Corollary 1.6; Appendix 2.1, for all large $l$, we have

$$E_{\mu_{\lambda^+}}[g(\eta(1))] \leq \varphi(2A) + \frac{C_0}{l} < \varphi(B - 2A) - \frac{C_0}{l} \leq E_{\mu_{\lambda^+}}[g(\eta(1))]$$

for some finite constant $C_0$. Hence, the expression appearing in the previous displayed formula vanishes exponentially fast as $l \uparrow \infty$. This concludes the proof of the lemma. \hfill \square

5.2. Proof of Theorem 1.6. Given Lemmas 4.1 and 5.1, the argument is similar to that in [6]. Recall $H(\rho) = E_{\nu_\rho}[h\bar{l}], H_1(\eta) = H(\eta(0))$, and $\tilde{H}_1(\rho) = E_{\rho}[H_1]$. Then, we have that

$$E_N \left[ \left| \int_0^t \{ h(\eta_s) - \frac{1}{\epsilon N} \sum_{x=1}^{\epsilon N} \tilde{H}_1(\eta_s^N(x)) \} \, ds \right| \right]$$

\[ \leq \ E_N \left[ \left| \int_0^t \{ h(\eta_s) - H(\eta_s^N(0)) \} \, ds \right| \right] 
+ \ E_N \left[ \left| \int_0^t \{ H(\eta_s^N(0)) - \frac{1}{\epsilon N} \sum_{x=1}^{\epsilon N} H(\eta_s^N(x)) \} \, ds \right| \right] 
+ \ E_N \left[ \left| \int_0^t \frac{1}{\epsilon N} \sum_{x=1}^{\epsilon N} \{ 1 - F(\eta_s^N(x)) - \tilde{H}_1(\eta_s^N(x)) \} \, ds \right| \right].$$

As $h$ and $H$ are bounded, Lipschitz by Lemma 5.5, the first and second terms vanish by Lemmas 4.1 and 5.1. The third term is recast as

$$E_N \left[ \left| \int_0^t \{ \frac{1}{\epsilon N} \sum_{x \in \mathbb{T}_N} \iota_x (x/N) \left( \tau_{\bar{\epsilon} N}(\eta_s) - \tilde{H}_1(\eta_s^N(x)) \right) \} \, ds \right| \right]$$

where $\iota_x(\cdot) = e^{-1} \cdot \{(0, \epsilon)\}$. It vanishes by Proposition 3.1 as $N \uparrow \infty$, and $\epsilon \downarrow 0$. \hfill \square

**Lemma 5.5.** Let $h : \mathbb{N} \to \mathbb{R}_+$ be a nonnegative, Lipschitz function for which there is a constant $C$ such that $kh(k) \leq Cg(k)$ for $k \geq 1$. Then, $H(\rho) = E_{\nu_\rho}[h(\eta(0))]$ is also nonnegative, bounded and Lipschitz, and vanishes at infinity.

**Proof.** It follows from the assumptions of the lemma that $h$ is bounded, as $g(k) \leq a_1 k$, and that $h$ vanishes at infinity. Hence, $H$, which is clearly positive, is also bounded. We claim that $H$ vanishes at infinity since

$$H(\rho) \leq \sup_{x \geq A} h(x) + \frac{1}{\rho} E_{\mu_\rho} \left[ h(\eta(0)) \{ \eta(0) \leq A \} \right] \leq \sup_{x \geq A} h(x) + \frac{A \| h \|_{L^\infty}}{\rho}.$$

To show $H$ is Lipschitz, it is enough to show $H'$ is absolutely bounded. Compute

$$H'(\rho) = \frac{\varphi'(\rho)}{\rho} \langle h(\eta(0)) \eta(0)^2 \rangle_{\mu_\rho} - \left\{ \frac{1}{\rho^2} + \frac{\varphi'(\rho)}{\varphi(\rho)} \right\} \langle h(\eta(0)) \eta(0) \rangle_{\mu_\rho}.$$

We first examine this expression for $\rho$ large. The second term, by the assumption $kh(k) \leq Cg(k)$, is bounded by $C\{ \varphi(\rho)/\rho^2 + \varphi'(\rho) \}$. A coupling argument shows that $\varphi'(\rho) \leq a$ if $a$ is a Lipschitz constant of the function $g$. On the other hand, $\varphi(\rho)/\rho^2 \leq a_1/\rho$ because $g(k) \leq a_1 k$.

Since $kh(k) \leq Cg(k)$ and since $E_{\mu_\rho}[g(\eta(0)) \eta(0)] = \varphi(\rho)(1 + \rho)$, the first term is bounded by $Ca(1 + \rho)/\rho$ if $a$ is a Lipschitz constant for $g$. This proves that $H'$ is absolutely bounded for $\rho$ large.

It is also not difficult to see that $H'(\rho)$ is bounded for $\rho$ close to 0. \hfill \square
