Abstract We consider the optimal approximation of arbitrary qubit states with respect to an available states consisting the eigenstates of two of three Pauli matrices, the $B_2$-distance of an arbitrary target state. Both the analytical formulae of the $B_2$-distance and the corresponding complete optimal decompositions are obtained. The trade-off relations for both the sum and the squared sum of the $B_2$-distances have been analytically and numerically investigated.

Keywords Optimal convex approximations of quantum states · $B_2$ distance · Trade-off relations

1 Introduction

Quantifying correlations among multipartite systems is one of the most important problems in quantum theory. However, most correlation measures become notorious difficult to calculate with the increasing partite and dimension. An alternative way to deal with the problem is to consider the distance of a given state to the so-called free states in resource theory. For example, entanglement is considered as the minimal distance of a given state to the set of separable states in quantum systems [1–4]. The
quantum discord is regarded as the minimal distance of a given state to classically correlated states [5]. And quantum coherence can be quantified by the optimal convex approximation of the given state to the reference orthogonal base [6].

While convexity is a very important property in mathematics and has been studied for long time, several related recent developments in quantum information have stimulated new interest in this topic [7,8]. The problem of optimal approximation to an unavailable quantum channel or state by the available channels or states was considered in [9,10] recently. It was shown that the optimally approximated distance has an natural operational interpretation. It can quantify the least distinguishable channel (state) from the given convex set to the target channel (state). The trace distance measure of coherence can be regarded as convex approximation to the target state with respect to a fixed base of the system, where the fixed base can be either orthogonal or nonorthogonal [11–15]. In Ref. [10], the author considered the $B_3$-distance, the distance from a target qubit state to the convex approximation of bases containing the eigenstates of all Pauli matrices. The optimal convex approximation on the $B_3$-distance has been obtained.

In this work, we focus on $B_2$-distance, the distance corresponding to the convex approximation of bases containing the eigenstates from one of the pairs of Pauli matrices. We investigate all the optimal convex decompositions for the desired quantum state. The paper is organized as follows. In Sect. 2, we calculate the $B_2$-distance in eight different cases, with the parameter regions achieving each optimal approximation explicitly given. In Sect. 3, we study trade-off relations for both the sum and the square sum of the $B_2$-distance.

2 The Pauli $B_2$-distance of qubit state

For an equal priori probability of two given quantum states $\rho$ and $\rho_0$, the optimal discrimination between them can be quantified by the following probability $p_{\text{discr}}(\rho, \rho_0)$,

$$p_{\text{discr}}(\rho, \rho_0) = \frac{1}{2} + \frac{1}{4} \| \rho - \rho_0 \|_1,$$

where $\| \rho \|_1$ denotes the trace norm of $\rho$, $\| \rho \|_1 = Tr \sqrt{\rho^\dagger \rho} = \sum_i \sqrt{r_i}$, $r_i$ are the eigenvalues of $\rho^\dagger \rho$.

The optimal convex approximation of the quantum state $\rho$ with respect to a given set $\rho_i$ is quantified by $D_{\{\rho_i\}}(\rho) = \min_{\{p_i\}} \{ \| \rho - \sum_i p_i \rho_i \|_1 \}$, and the best approximated points are the set $S(\rho^{\text{opt}}) = \{ \rho^{\text{opt}} | D_{\{\rho_i\}}(\rho) = \| \rho - \rho^{\text{opt}} \|_1 \}$.

This optimal convex approximation provides the worst probability of discriminating the desired state $\rho$ from any of the available states $\sum_i p_i \rho_i$. For any other figure of merit that quantifies the distance between quantum states, the optimal convex approximation can be similarly defined (e.g., by a decreasing function of the fidelity). We remind that the best approximation can be arrived at many points and $S(\rho^{\text{opt}})$ represents the set of all the optimal points achieving the minimum distance.

Let $|0\rangle$ and $|1\rangle$, $|2\rangle \equiv \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle)$ and $|3\rangle \equiv \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle)$, and $|4\rangle \equiv \frac{1}{\sqrt{2}}(|0\rangle + \sqrt{-1}|1\rangle)$ and $|5\rangle \equiv \frac{1}{\sqrt{2}}(|0\rangle - \sqrt{-1}|1\rangle)$ be the eigenstates of the Pauli matrices $\sigma_z$, $\sigma_x$, and $\sigma_y$, respectively. We consider the following available set of states,
Complete optimal convex approximations of qubit states… Page 3 of 11

B_2' = \left\{ |0\rangle, |1\rangle, |2\rangle \equiv \frac{1}{\sqrt{2}} (|0\rangle + |1\rangle), |3\rangle \equiv \frac{1}{\sqrt{2}} (|0\rangle - |1\rangle) \right\},

B_2'' = \left\{ |0\rangle, |1\rangle, |4\rangle \equiv \frac{1}{\sqrt{2}} (|0\rangle + \sqrt{-1}|1\rangle), |5\rangle \equiv \frac{1}{\sqrt{2}} (|0\rangle - \sqrt{-1}|1\rangle) \right\},

B_2''' = \left\{ |2\rangle = \frac{1}{\sqrt{2}} (|0\rangle + |1\rangle), |3\rangle = \frac{1}{\sqrt{2}} (|0\rangle - |1\rangle), |4\rangle = \frac{1}{\sqrt{2}} (|0\rangle + \sqrt{-1}|1\rangle), |5\rangle \equiv \frac{1}{\sqrt{2}} (|0\rangle - \sqrt{-1}|1\rangle) \right\},

(1)

where B_2' contains the eigenstates of \sigma_x, \sigma_z, B_2'' the eigenstates of \sigma_y, \sigma_z and B_2''' the eigenstates of \sigma_x, \sigma_y. The target qubit state \rho can be parameterized by

\rho = \left( \begin{array}{c}
1 - a \\
k \sqrt{a(1 - a)} e^{\sqrt{-1} \phi} \\
ak \end{array} \right),

(2)

with a \in [0, 1], \phi \in [0, 2\pi], and k \in [0, 1] \[10\]. Since the B_2-distance is invariant under the state transformations \rho(a, k, \phi) \rightarrow \rho(1 - a, k, \phi) and \rho(a, k, n\pi/2 \pm \phi) \rightarrow \rho(a, k, \phi) (with integer n), we can restrict our study on the case a \in [0, 1/2] and \phi \in [0, \pi/2].

For any given target quantum state \rho and available basis set in Eq. (1), we reduce the optimal approximation problem to find the minimum \( D_{B_2}(\rho) = \min_{\{p_i\}} \{\|\rho - \sum p_i |e_i\rangle \langle e_i|\|_1\} \) with respect to the probabilities \{p_i\}, where \{|e_i\rangle\} represent the states of B_2', B_2'' or B_2''' in Eq. (1). Denote \rho_i = |i\rangle \langle i|. The original problem is reduced to the optimal approximation problem of finding the minimum distance

\[ D_{B_2}(\rho) = \min_{\{p_i\}} \left\{ 2 \sqrt{|\text{Det}(\rho - \sum p_i \rho_i)|} \right\} \]

such that \( p_i \geq 0, \sum_j p_j = 1 \).

We first consider the B_2' distance, i.e., \( D_{B_2'}(\rho) = \min_{\{p_i\}} \{2 \sqrt{|\text{Det}(\rho - \sum_{i=0}^{3} p_i \rho_i)|} \} \). Set

\[ f(p_0, p_1, p_2, p_3) = |\text{Det} \left( \rho - \sum_{i=0}^{3} p_i \rho_i \right) | - \sum_{i=0}^{3} \lambda_i p_i | - \sum_{i=0}^{3} p_i. \]

Since the constraint inequality condition sets \( p_i \geq 0 \) is convex and the equality constraint \( \sum_j p_j = 1 \) is linear, by the Karush–Kuhn–Tucker theorem \[20\], the following KKT condition must be satisfied while solving the above optimization problem.

\[ \frac{\partial f}{\partial p_i} = 0, \lambda_i p_i = 0, \lambda_i \geq 0, p_i \geq 0, \sum_{j=0}^{3} p_j = 1, i = 0, 1, 2, 3, \]

(3)
Eq. (3) reduces to the following equations,

\[ p_1 + \frac{1}{2} p_2 + \frac{1}{2} p_3 + \lambda_0 + \lambda - a = 0, \]
\[ p_0 + \frac{1}{2} p_1 + \frac{1}{2} p_3 + \lambda_1 + \lambda - 1 + a = 0, \]
\[ \frac{1}{2} p_0 + \frac{1}{2} p_1 + p_3 + \lambda_2 + \lambda + k\sqrt{a(1 - a)} \cos \phi - \frac{1}{2} = 0, \]
\[ \frac{1}{2} p_0 + \frac{1}{2} p_1 + p_2 + \lambda_3 + \lambda - k\sqrt{a(1 - a)} \cos \phi - \frac{1}{2} = 0, \]
\[ \lambda_i p_i = 0, \quad \lambda_i \geq 0, \quad p_i \geq 0, \quad i = 0, 1, 2, 3, \]
\[ \sum_i p_i = 1. \]

Solving the above equations, we can obtain the complete analytical solutions to the optimal convex approximation \( \rho^{opt} \) of \( \rho \). The \( S(\rho^{opt}) \) of \( \rho \) with respect to \( B'_2 \) is given as

(i) For \( a \geq k\sqrt{a(1 - a)} \cos \phi \), we have

\[ D_{B'_2}(\rho) = 2k\sqrt{a(1 - a)} \sin \phi = \langle \sigma_y \rangle, \quad (4) \]

which is attained at

\[ p_0 = 1 - a - k\sqrt{a(1 - a)} \cos \phi - t, \]
\[ p_1 = a - k\sqrt{a(1 - a)} \cos \phi - t, \]
\[ p_2 = 2k\sqrt{a(1 - a)} \cos \phi + t, \]
\[ p_3 = t, \quad (5) \]

where \( t \) satisfies \( a - k\sqrt{a(1 - a)} \cos \phi \geq t \geq 0 \). Let \( A'_1 = \{ \Sigma_{i=0}^{3} p_i \rho_i \} \) denote the set of states with \( p_i \) given by Eq. (5). Then \( A'_1 \) contains all the optimal points achieving the distance \( D_{B'_2}(\rho) \) in Eq. (4).

(ii) For \( a < k\sqrt{a(1 - a)} \cos \phi \), we have the optimal convex approximation distance

\[ D_{B'_2}(\rho) = \sqrt{2(1 + \sin^2 \phi)k^2(a(1 - a)) - 4a \cos \phi k\sqrt{a(1 - a)} + 2a^2} \]
\[ = \sqrt{\langle \sigma_y \rangle^2 + \frac{1}{2}(\langle \sigma_x \rangle + \langle \sigma_z \rangle - 1)^2}, \quad (6) \]

which is attained with

\[ p_0 = 1 - a - k\sqrt{a(1 - a)} \cos \phi, \]
\[ p_2 = a + k\sqrt{a(1 - a)} \cos \phi, \]
\[ p_1 = p_3 = 0. \quad (7) \]
Denote \( A'_2 = \{ p_0 \rho_0 + p_2 \rho_2 \} \), with \( p_0, p_2 \) given by Eq. (7). Then \( A'_2 \) contains all the optimal states achieving the distance \( D_{B'_2} (\rho) \) in Eq. (6). Therefore, \( S(\rho^{opt}) \) is given by \( S(\rho^{opt}) = A'_1 \cup A'_2 \), which is the set of optimal states that gives rise to the optimal convex approximations.

Next we consider the optimal convex approximation of \( \rho \) with respect to \( B''_2 \). Namely, \( D_{B''_2} (\rho) = \min_{\{ p_i \}} \{ 2 \sqrt{| \text{Det}(\rho - \sum_{i=0,1,4,5} p_i \rho_i) |} \} \). Similar to the case of \( B'_2 \), we have

(i) For \( a \geq k \sqrt{a (1 - a) \sin \phi} \), the optimal convex approximated distance is given by

\[
D_{B''_2} (\rho) = 2 k \sqrt{a (1 - a) \cos \phi} = \langle \sigma_x \rangle. \tag{8}
\]

With the optimal probability weights are given by

\[
\begin{align*}
p_0 &= 1 - a - k \sqrt{a (1 - a) \sin \phi} - t, \\
p_1 &= a - k \sqrt{a (1 - a) \sin \phi} - t, \\
p_4 &= 2 k \sqrt{a (1 - a) \sin \phi} + t, \\
p_5 &= t,
\end{align*}
\]

where \( t \) satisfies \( a - k \sqrt{a (1 - a) \sin \phi} \geq t \geq 0 \). Denote \( A''_1 = \{ \sum p_i \rho_i \} \) with \( p_i \) given by Eq. (9). Then \( A''_1 \) contains all the optimal states achieving the distance \( D_{B''_2} (\rho) \) in Eq. (8).

(ii) For \( a < k \sqrt{a (1 - a) \sin \phi} \), we have the optimal convex approximated distance

\[
D_{B''_2} (\rho) = \sqrt{2 (1 + \cos^2 \phi) k^2 (a (1 - a)) - 4 a \sin \phi k \sqrt{a (1 - a)} + 2 a^2} \\
= \sqrt{\langle \sigma_x \rangle^2 + \frac{1}{2} (\langle \sigma_y \rangle + \langle \sigma_z \rangle - 1)^2}, \tag{10}
\]

with the optimal probability weights given by

\[
\begin{align*}
p_0 &= 1 - a - k \sqrt{a (1 - a) \sin \phi}, \\
p_4 &= a + k \sqrt{a (1 - a) \sin \phi}, \\
p_1 = p_5 &= 0.
\end{align*}
\]

Let \( A''_2 = \{ p_0 \rho_0 + p_4 \rho_4 \} \) be the set of states with \( p_0 \) and \( p_4 \) given by Eq. (11). Then \( S(\rho^{opt}) \) is given by \( S(\rho^{opt}) = A''_1 \cup A''_2 \).

For the optimal approximation of \( \rho \) with respect to the basis in \( B'''_2 \), we have

(i) For \( 1/2 \geq k \sqrt{a (1 - a) (\sin \phi + \cos \phi)} \), the optimal convex approximated distance has the form

\[
D_{B'''_2} (\rho) = (1 - 2a) = \langle \sigma_z \rangle, \tag{12}
\]

\textcircled{2} Springer
with the optimal probability weights

\[ p_2 = 1/2 + k\sqrt{a(1-a)}(\cos \phi - \sin \phi) - t, \]
\[ p_3 = 1/2 - k\sqrt{a(1-a)}(\cos \phi + \sin \phi) - t, \]
\[ p_4 = 2k\sqrt{a(1-a)} \sin \phi + t, \]
\[ p_5 = t, \]

where \( t \) is given by \( 1/2 \geq k\sqrt{a(1-a)}(\sin \phi + \cos \phi) \geq t \geq 0 \). Hence, \( A''_1 = \{ \Sigma p_i \rho_i \} \), with \( p_i \) given by Eq. (13), contains all the optimal states achieving the distance \( D_{B''_2}(\rho) \) in Eq. (12).

(ii) For \( 1/2 < k\sqrt{a(1-a)}(\sin \phi + \cos \phi) \), we have

\[ D_{B''_2}(\rho) = \sqrt{(1-2a)^2 + 2(k\sqrt{a(1-a)}(\cos \phi + \sin \phi) - 1/2)^2} \]
\[ = \sqrt{\langle \sigma_z \rangle^2 + \frac{1}{2}(\langle \sigma_y \rangle + \langle \sigma_x \rangle - 1)^2}, \]

with the optimal probability weights given by

\[ p_2 = 1/2 + k\sqrt{a(1-a)}(\cos \phi - \sin \phi), \]
\[ p_4 = 1/2 - k\sqrt{a(1-a)}(\cos \phi - \sin \phi), \]
\[ p_3 = p_5 = 0. \]

Denoting \( A''_2 = \{ p_2 \rho_2 + p_4 \rho_4 \} \), with \( p_2 \) and \( p_4 \) given by Eq. (15), we have \( S(\rho^{opt}) = A''_1 \cup A''_2 \), which is the set of states achieving all the optimal convex approximations.

In Fig. 1, we plot the distance \( D_{B'_2}(\rho) \) for fixed parameters of \( k \) and \( \phi \). One can see that for the fixed value \( \phi = \frac{\pi}{4} \), Fig. 1a shows that the optimal distance \( D_{B'_2}(\rho) \) increases with \( k \) and decreases with the parameter \( a \). Figure 1c shows the interface such that the region above the surface corresponds to the case (i), namely, \( a \geq k\sqrt{a(1-a)} \cos \phi \); and the region below the surface is the case (ii), \( a < k\sqrt{a(1-a)} \cos \phi \). In Figs. 2 and 3, the distances \( D_{B'_2}(\rho) \) and \( D_{B''_2}(\rho) \) with the fixed values are also plotted, respectively. The corresponding interface is plotted in Fig. 2c (Fig. 3c): the region above the surface corresponds to the case \( a \geq k\sqrt{a(1-a)} \sin \phi \); \( 1/2 \geq k\sqrt{a(1-a)}(\sin \phi + \cos \phi) \)), the region below the surface is the case \( a < k\sqrt{a(1-a)} \sin \phi \); \( 1/2 < k\sqrt{a(1-a)}(\sin \phi + \cos \phi) \)), respectively.

### 3 Trade-off relations among the \( B_2 \)-distances

We have calculated the optimal distances \( D_{B'_2}(\rho) \), \( D_{B''_2}(\rho) \) and \( D_{B'''_2}(\rho) \), with explicit formulae for arbitrary qubit state \( \rho \) classified in two parameter regions each. Interestingly, we find that the sum and the squared sum of \( D_{B'_2}(\rho) \), \( D_{B''_2}(\rho) \) and \( D_{B'''_2}(\rho) \) display some trade-off relations in each parameter region.
Fig. 1 Optimal convex approximation of a qubit mixed state w.r.t. the set $B_2'$ spanned by the eigenstates of the Pauli matrices $\sigma_z$ and $\sigma_x$. The distance $D_{B_2'}(\rho)$ is plotted versus the target state parameters $a$, $k$ and $\phi$, for fixed value of the parameter $\phi = \frac{\pi}{4}$ (a), for fixed value of the parameter $k = 4/5$ (b). The interface of the regions of the two cases (i) and (ii) is plotted in c, the region above the surface corresponds to the case $a \geq k \sqrt{a(1-a)} \cos \phi$, the region below the surface is the case $a < k \sqrt{a(1-a)} \cos \phi$. a $\phi = \pi/4$. b $k = 4/5$. c Area of the interface

Fig. 2 Optimal convex approximation of a qubit mixed state $\rho$ w.r.t. the set $B_2''$ spanned by the eigenstates of the Pauli matrices $\sigma_z$ and $\sigma_y$. The distance $D_{B_2''}(\rho)$ is plotted for fixed value of the parameter $\phi = \frac{\pi}{4}$ (a), and for fixed value of the parameter $k = 4/5$ (b). The interface of the regions of the two cases (i) and (ii) is plotted in c, the region above the surface corresponds to the case $a \geq k \sqrt{a(1-a)} \sin \phi$, the region below the surface is the case $a < k \sqrt{a(1-a)} \sin \phi$. a $\phi = \pi/4$. b $k = 4/5$. c Area of the interface

Fig. 3 Optimal convex approximation of a qubit mixed state $\rho$ w.r.t. the set $B_2'''$ spanned by the eigenstates of the Pauli matrices $\sigma_x$ and $\sigma_y$. The distance $D_{B_2'''}(\rho)$ is plotted for fixed value of the parameter $\phi = \frac{\pi}{4}$ (a) and for fixed value of the parameter $k = 4/5$ (b). The interface of the regions of the two cases (i) and (ii) is plotted in c, the region above the surface corresponds to the case $1/2 \geq k \sqrt{a(1-a)}(\sin \phi + \cos \phi)$, the region below the surface is the case $1/2 < k \sqrt{a(1-a)}(\sin \phi + \cos \phi)$. a $\phi = \pi/4$. b $k = 4/5$. c Area of the interface
Let $1^\circ$ represents the parameter region of the state $\rho$ with $a \geq k \sqrt{a(1-a) \cos \phi}$, and $2^\circ$ the parameter region $a < k \sqrt{a(1-a) \cos \phi}$. Similarly, $3^\circ$ ($4^\circ$) represents the parameter region with $a \geq k \sqrt{a(1-a) \sin \phi}$ ($a < k \sqrt{a(1-a) \sin \phi}$), and $5^\circ$ ($6^\circ$) represents the parameter region with $\frac{1}{2} \geq k \sqrt{a(1-a) \cos \phi}$ ($\frac{1}{2} < k \sqrt{a(1-a) \cos \phi}$). For every $D_{B_2}^t(\rho)$ ($D_{B_2}^m(\rho)$) there are two parameter regions: i) and ii). A state $\rho$ may belong to the region $1^\circ$ in calculating the distance $D_{B_2}^t(\rho)$, but to region $4^\circ$ in calculating $D_{B_2}^m(\rho)$, and to region $5^\circ$ in calculating $D_{B_2}^m(\rho)$. Therefore, we have all together eight cases of parameter regions

| Region 1 | $1^\circ \cap 3^\circ \cap 5^\circ$ | Region 3 | $1^\circ \cap 3^\circ \cap 6^\circ$ | Region 5 | $2^\circ \cap 3^\circ \cap 5^\circ$ | Region 7 | $1^\circ \cap 4^\circ \cap 6^\circ$ |
|-----------------|---------------------------------|-----------|---------------------------------|-----------|---------------------------------|-----------|---------------------------------|
| Region 2 | $2^\circ \cap 3^\circ \cap 5^\circ$ | Region 4 | $1^\circ \cap 4^\circ \cap 6^\circ$ | Region 6 | $2^\circ \cap 3^\circ \cap 6^\circ$ | Region 8 | $2^\circ \cap 4^\circ \cap 6^\circ$ |

For each case, the three $B_2$-distances display different values. In Fig. 4, we plot the minimum $min_{\rho} D_{B_2}(\rho) = min\{D_{B_2}^t(\rho), D_{B_2}^m(\rho), D_{B_2}^m(\rho)\}$. One can see from Fig. 4 that, for fixed $\phi = \pi/4$ and $k = 4/5$, $min_{\rho} D_{B_2}(\rho)$ is always nonzero for nonzero parameters $a$ and $k$ or $\phi$, namely, all the three Pauli $B_2$-distances are nonzero.

Concerning the trade-off relations of the three Pauli $B_2$-distances, for convenience, we denote

$$D_{B_2}(\rho) = D_{B_2}^t(\rho) + D_{B_2}^m(\rho) + D_{B_2}^m(\rho),$$  
$$D_{B_2}(\rho)^2 = D_{B_2}^t(\rho)^2 + D_{B_2}^m(\rho)^2 + D_{B_2}^m(\rho)^2.$$ 

---

See Springer
By the numerical calculation, we obtain the trade-off relation among $D_{B_2'}(\rho)$, $D_{B_2''}(\rho)$ and $D_{B_2'''}(\rho)$, see the following table:

| Region | $D_{B_2}(\rho)$ | $D_{B_2}(\rho)^2$ | Region | $D_{B_2}(\rho)$ | $D_{B_2}(\rho)^2$ |
|--------|-----------------|--------------------|--------|-----------------|--------------------|
| 1      | [0.1, 1.742)    | [0.1]              | 5      | [1.1, 1.742)    | (0.501, 1.086)     |
| 2      | (1.006, 1.750)  | (0.666, 1.068)     | 6      | (1.1, 1.742)    | (0.666, 1.068)     |
| 3      | [1.1, 1.742)    | (0.501, 1.086)     | 7      | (1.1, 1.742)    | (0.666, 1.068)     |
| 4      | [1.1, 1.742)    | (0.501, 1.086)     | 8      | (1.5, 1.765)    | (0.750, 1.060)     |

Figure 5 shows all the parameter regions of $a$, $k$, $\phi$ such that the three $B_2$-distances are achieved. These regions completely characterize all the optimal convex approximations of a state $\rho$ w.r.t. $B_2$-distance.

It has been shown that, for a given state, the three optimal distances to the bases in $B_2'$, $B_2''$ and $B_2'''$ satisfy a kind of trade-off relations. In fact, the bounds on $D_{B_2}(\rho) = D_{B_2'}(\rho) + D_{B_2''}(\rho) + D_{B_2'''}(\rho)$ or $D_{B_2}(\rho)^2 = D_{B_2'}(\rho)^2 + D_{B_2''}(\rho)^2 + D_{B_2'''}(\rho)^2$ are tightly related to the quantum uncertainty relations satisfied by the three Pauli operators, since both the distances and the standard deviations of the Pauli operators are given by the mean values of the Pauli operators. From $\langle \sigma_x \rangle^2 + \langle \sigma_y \rangle^2 + \langle \sigma_z \rangle^2 = 4k^2a(1-a)\sin^2\varphi + 4k^2a(1-a)\cos^2\varphi + (1 - 2a)^2 \leq 1$, one gets $\Delta S_x^2 + \Delta S_y^2 + \Delta S_z^2 \geq 1/2$, where $\Delta S_x$ ($\Delta S_y$, $\Delta S_z$) is the standard deviation and $\Delta S_x = \sqrt{1 - \langle \sigma_x \rangle^2}$. On the other hand $|\langle \sigma_x \rangle| + |\langle \sigma_y \rangle| + |\langle \sigma_z \rangle| = 2\sqrt{a(1-a)} + 1 - 2a \leq 3\sqrt{2}/8$. Therefore, we have

$$(\Delta S_x)^2 + (\Delta S_y)^2 + (\Delta S_z)^2 \geq \frac{\tau}{2} \left( |\langle \sigma_x \rangle| + |\langle \sigma_y \rangle| + |\langle \sigma_z \rangle| \right),$$

where $\tau = \frac{2}{\sqrt{3}}$ is the triple constant given in the uncertain relations in [21, 22]. From formulae (4), (8) and (12), we immediately get that in region 1, our Pauli $B_2$-distances is in accordance with the uncertainty relation.
4 Conclusion

In summary, we have shown that a qubit mixed state $\rho$ can be approximated by a number of effectively available pure states spanned by the eigenstates of the Pauli matrices. It is well known that correlation limits the extractable information [16–19], where one does want to minimize the probability of discrimination. The advantage of our results is that we presented the complete set of optimal decompositions of a given state. In [10] for a given state, only one particular optimal decomposition has been elegantly derived, in which $p_3$ and $p_5$ are chosen to be zero. Hence, basically it is the minimal distance with respect to four of six eigenvectors of the Pauli matrices. As a simple example, consider the following mixed qubit state, $\rho = \left( \begin{array}{cc} 1/2 & 1/5 \\ 1/5 & 1/2 \end{array} \right)$. One can verify that $D_{\rho'}(\rho) = 0$. All the optimal convex approximation points with respect to the basis $\{|0\rangle, |1\rangle, |2\rangle, |3\rangle\}$ are given by Eq. (5). If we choose $t = 0$, then we obtain $\rho = 0.3\rho_0 + 0.3\rho_1 + 0.4\rho_2$. Moreover, we also have $D_{\rho''}(\rho) = 0$. The optimal convex approximation points with respect to the basis $\{|2\rangle, |3\rangle, |4\rangle, |5\rangle\}$ are given by Eq. (13), also for $t = 0$, one obtains the optimal decomposition, $\rho = 0.7\rho_2 + 0.3\rho_3$. In [10], only one optimal decomposition $\rho = 0.3\rho_0 + 0.3\rho_1 + 0.4\rho_3$ is obtained. Other optimal decompositions like $\rho = 0.7\rho_2 + 0.3\rho_3$ cannot be obtained even considering the optimal convex approximation with respect to the full bases $\{|0\rangle, |1\rangle, |2\rangle, |3\rangle, |4\rangle, |5\rangle\}$.

It is obvious that $B_3$-distance $D_{B_3}(\rho)$ is always less than the $B_2$-distance $\min D_{B_2}(\rho)$, since the approximate point in $D_{\rho'}(\rho)$, $D_{\rho''}(\rho)$ and $D_{\rho'''}(\rho)$ is contained in $D_{B_3}(\rho)$. For more detail, for $k = \frac{4}{7}$, compare $\min D_{B_2}(\rho)$ and $D_{B_3}(\rho)$ in [10] in the region $a \times \phi = [0, \frac{1}{7}] \times [0, \frac{\pi}{4}]$, one can find that $\min D_{B_2}(\rho) = D_{B_3}(\rho)$ about twenty percent of the region, while in the remaining eighty percent region, $D_{B_3}(\rho)$ is always less than $\min D_{B_2}(\rho)$, when $a = \frac{1}{7}, \phi = \frac{\pi}{4}$, the maximal difference of $D_{B_3}(\rho)$ and $\min D_{B_2}(\rho)$ can be attained to 0.213, from which one can obtain that the for some case $D_{B_3}(\rho)$ is equal to $\min D_{B_2}(\rho)$ while for some other case $D_{B_3}(\rho)$ is less than $\min D_{B_2}(\rho)$, this is because two eigenstates of the Pauli matrices are discarded in the computation of $B_2$-distance. Therefore, the research of the best convex approximation about $B_2$-distance may provide an alternative way to analyze the optimal convex approximation about $B_3$-distance. Our approach may be also used to study other kinds of optimal decompositions associated with other bases.
