I. INTRODUCTION

Quantum and thermal fluctuations of electromagnetic fields, which give rise to Planck’s law of blackbody radiation [1], are responsible for radiative energy, momentum and entropy transfer [2–12]. Classical theory of thermal radiation takes only propagating waves into consideration. Presence of evanescent waves nearby the surfaces leads to near-field effects, such as interference, diffraction and tunneling of surface waves, which are important when the size and length scale is comparable to the thermal wavelength of objects (∼ 10 µm at room temperature 300 K). Thermal radiation due to fluctuations of electromagnetic fields for a single and/or coated object has been investigated well over the past few decades. For example, Rytov investigated the thermal radiation of a spherical body based on his proposed formalism of electromagnetic fluctuations [2], Eckhardt summerized and compared two methods, Rytov’s fluctuation-dissipation theorem and Langevin theory (stochastic electrodynamics) to study the radiative heat transfer [13], Kattawar and Eisner used Rytov’s formalism to calculate the radiative power from a homogeneous isothermal sphere of arbitrary size [14], Kruger et al. discussed radiative heat transfer and Casimir force from a cylinder emphasizing its polarized nature [15], Golyk et al. explored the radiation from a long cylinder at uniform temperature when the radius of the cylinder is much smaller than the thermal wavelength [16], Barabanenkov et al. explored the coherent effect of thermal microwave radiation from a heated body [17], and others [18–22]. Near-field radiative energy and momentum transfer between flat and curved surfaces have been studied for the past years. Enhancement of radiative energy transfer, wavelength selectivity, and size and scale dependence are typical characteristics of near-field phenomena which make it more interesting. These characteristics could be exploited in many potential nanotechnological applications such as nanoparticles [23–26] and wavelength selective absorber and emitters [27–31]. Fluctuations in electromagnetic fields due to the presence of boundaries create van der Waals pressures which lead to momentum transfer [32–35]. These phenomena can be described by cross-spectral densities of the electromagnetic field using dyadic Green’s functions of vector Helmholtz equation [36–38]. Such a relation between near-field radiative energy and momentum transfer for arbitrarily shaped objects has been explicitly derived in Ref. [37].

During the past decades, many theoretical works have been published on the topic of the enhanced thermal radiation due to near-field effects and fluctuation-induced van der Waals pressures. Most of them are focused on the configurations, for example, between planar multilayered structures [39–43], coated planar surface [44], photonic multilayer crystals [45–47], gratings [48, 49], cylindrical objects [50, 51], spheres [23, 52–55], a sphere and a flat plate [26, 55–57], and hyperbolic structures [58–60]. Although considerable amount of work devoted to theoretical and experimental results for near-field radiative energy transfer and momentum transfer between objects of the abovementioned typical geometries, these phenomena for a single object requires a further study and a good understanding when the size of the object is reduced to be comparable or less than the thermal wavelength. To the best of our knowledge, most of the works on an individual body rely directly on Rytov’s formalism for fluctuating electromagnetic fields [2]. In this work, we applied Rytov’s approach and developed a dyadic Green’s function formalism for spectral emissivity and van der Waals contribution to surface energy for micro and nano-sized spherical objects, such as a single sphere, a bubble, a spherical shell and a coated sphere, as shown in Fig. 1.

This paper demonstrates how fluctuational electrodynamics can be used to determine spectral emissivity and van der Waals contribution to surface energy for various shapes in a homogeneous and isotropic medium. The dyadic Green’s function formalism of radiative heat transfer and van der Waals stress for different spherical configurations has been developed. Size dependence and wavelength selectivity of micro and nano-sized spheres are clearly observed. For small sized objects, the emissiv-
ity spectra show sharp peaks at wavelengths corresponding to characteristics of the material’s refractive index. The peaks increase as the size of the object decreases. This is consistent with spectral emissivity calculations done for thin films as in Ref. [31]. The calculations for a spherical bubble show that as radius of the bubble reduces, van der Waals energy contribution to the total surface energy increases and dominates it beyond a critical value.

The paper is arranged as follows. Section II focuses on the theoretical formulations for near-field radiative energy transfer and momentum transfer for a generalized case. Calculations of transmissivity for radiative energy transfer and fluctuation-induced van der Waals pressure are discussed in Sec. II A and Sec. II B, respectively. Using this formalism, the analytical expressions of Mie reflection and transmission coefficients for specific cases of a sphere, a bubble, a spherical shell and a coated sphere in a homogeneous and isotropic medium are obtained in Sec. III. Formulae for calculations of spectral emissivity and van der Waals contribution to surface energy of a spherical body are subsequently derived in Sec. III A and Sec. III B. We recapitulate the paper and states the conclusions in Sec. IV.

II. THEORETICAL FUNDAMENTALS

The fluctuations of electric and magnetic current densities, which give rise to radiative transfer and fluctuation-induced electromagnetic forces, can be described by the fluctuation-dissipation theorem [61–63]:

\[
\langle J_p^m(r)J_{q \ast}^m(\bar{r}) \rangle = 2\omega \varepsilon \varepsilon''(\Theta(\omega, T)) \delta(r - \bar{r}) \delta_{pq}
\]

(3a)

\[
\langle J_p^m(r)J_{q \ast}^m(\bar{r}) \rangle = 2\omega \mu \mu''(\Theta(\omega, T)) \delta(r - \bar{r}) \delta_{pq}
\]

(3b)

\[
\langle J_p^m(r)J_{q \ast}^m(\bar{r}) \rangle = 0
\]

(3c)

where \( r \) and \( \bar{r} \) are source position vector and observation position vector, \( \varepsilon \) and \( \mu \) are the permittivity and permeability of free space, \( J_p^m \) and \( J_{q \ast}^m \) are the Cartesian components \( (p, q = 1, 2, 3) \) of the electric and magnetic current densities, \( \Theta(\omega, T) = \frac{\hbar \omega}{2k_B T} \), \( \varepsilon'' \) and \( \mu'' \) are the imaginary parts of the dielectric permeability and magnetic permeability respectively, \( J^* \) is the complex conjugate of \( J \), and \( \langle \rangle \) denotes the ensemble average.

\( 2\pi \hbar \) is the Planck constant and \( k_B \) is the Boltzmann constant. The presence of \( \delta_{pq} \) implies that all materials are isotropic, and that of \( \delta(r - \bar{r}) \) implies that the correlations of sources are local.

The Fourier transforms of the electric and magnetic fields due to thermal sources in any object (volume \( V_s \)) are given by [2, 37]

\[
E(\bar{r}) = \int_{V_s} \left[ \mathbf{p}(r) \cdot \mathbf{G}_e(r, \bar{r}) - J^m(r) \cdot \mathbf{G}_E(r, \bar{r}) \right] d\mathbf{r} \quad (2a)
\]

\[
H(\bar{r}) = \int_{V_s} \left[ \mathbf{m}(r) \cdot \mathbf{G}_m(r, \bar{r}) + J^* \cdot \mathbf{G}_M(r, \bar{r}) \right] d\mathbf{r} \quad (2b)
\]

where \( \mathbf{p}(r) = i\omega \mu_\sigma \mu(r) \mathbf{J}^p(r) \), \( \mathbf{m}(r) = i\omega \varepsilon_\sigma \varepsilon(r) \mathbf{J}^m(r) \), and, \( \varepsilon(r) \) and \( \mu(r) \) are the permittivity and permeability at location \( r \). The Fourier transforms of the electric field at location \( \bar{r} \), \( \mathbf{G}_E(r, \bar{r}) = \nabla \times \mathbf{G}_e(r, \bar{r}) \) and \( \mathbf{G}_M(r, \bar{r}) = \nabla \times \mathbf{G}_m(r, \bar{r}) \). The functions \( \mathbf{G}_e(r, \bar{r}) \) and \( \mathbf{G}_m(r, \bar{r}) \) are dyadic Green’s functions of the vector Helmholtz equation that satisfy the following boundary conditions on the interface between object 1 and object 2. For electric dyadic Green’s functions,

\[
\hat{n}_1 \times \mu_1 \mathbf{G}_e(r_1, \bar{r}) = \hat{n}_2 \times \mu_2 \mathbf{G}_e(r_2, \bar{r}), \quad (3a)
\]

\[
\hat{n}_1 \times \mathbf{G}_E(r_1, \bar{r}) = \hat{n}_2 \times \mathbf{G}_E(r_2, \bar{r}), \quad (3b)
\]

and for magnetic dyadic Green’s functions,

\[
\hat{n}_1 \times \varepsilon_1 \mathbf{G}_m(r_1, \bar{r}) = \hat{n}_2 \times \varepsilon_2 \mathbf{G}_m(r_2, \bar{r}), \quad (3c)
\]

\[
\hat{n}_1 \times \mathbf{G}_M(r_1, \bar{r}) = \hat{n}_2 \times \mathbf{G}_M(r_2, \bar{r}), \quad (3d)
\]

where \( \hat{n}_1 \) and \( \hat{n}_2 \) are surface normal vectors, and \( r_1 \) and \( r_2 \) are position vectors of points on either side of interface in volume \( V_1 \) and \( V_2 \), as \( |r_1 - r_2| \rightarrow 0 \).

A. Transmissivity for radiative energy transfer

The steady state radiative heat transfer from object 1 to object 2, \( Q_{1 \rightarrow 2} \), is given by

\[
Q_{1 \rightarrow 2} = -\int_{S_2} \mathbf{P}(\bar{r}) \cdot \hat{n}_2 d\bar{r} \quad (4)
\]

where \( \mathbf{P}(\bar{r}) = \langle \mathbf{E}(\bar{r}, t) \times \mathbf{H}(\bar{r}, t) \rangle \) is the Poynting vector at \( \bar{r} \in S_2 \) due to thermally fluctuating sources within \( V_1 \). The “-” sign in front of the surface integral is because \( \hat{n}_2 \) is the outward pointing normal on the surface \( S_2 \). The components of \( \mathbf{P}(\bar{r}) \) are given by

\[
P_q(\bar{r}) = \epsilon_{ipq} \langle E_p(\bar{r}, t) H_q(\bar{r}, t) \rangle \quad (5)
\]

where \( p, q = 1, 2, 3 \) are the labels for the Cartesian components of the vector, \( \epsilon_{ipq} \) is the Levi-Civita symbol, \( \langle E_p(\bar{r}, t) H_q(\bar{r}, t) \rangle \) is the contribution to \( \langle E_p(\bar{r}, t) H_q(\bar{r}, t) \rangle \) from sources within \( V_1 \). We note that \( \langle E_q(\bar{r}, t) H_p(\bar{r}, t) \rangle = \int \frac{d\omega}{2\pi} \langle E_q(\bar{r}, \omega) H_p(\bar{r}, \omega) \rangle \). Using Eq. 2a and Eq. 2b, Eq. 4 for \( Q_{1 \rightarrow 2} \) can be re-written as

\[
Q_{1 \rightarrow 2} = \int_0^\infty \frac{d\omega}{2\pi} \left[ \Theta(\omega, T_1) - \Theta(\omega, T_2) \right] T_{rr}(\omega) \quad (6)
\]

where \( T_1 \) and \( T_2 \) are the absolute temperatures of objects 1 and 2, and \( T_{rr}(\omega) \) is a generalized transmissivity for radiative energy transport between objects 1 and 2. \( T_{rr}(\omega) \) can be expressed exclusively in terms of components of the dyadic Green’s functions on the surfaces of objects 1 and 2, which is given by [37]
FIG. 1. Schematic of various spherical geometries. (a) a sphere of radius \( r \) (material 1, green), (b) a bubble of radius \( r \) in material 2 (blue), (c) a spherical shell of interior and exterior radii \( r_1 \) and \( r_2 \) (material 2, orange), and (d) a sphere of radius \( r_1 \) (material 1, green) coated with a thin film of thickness \( r - r_1 \) (material 2, orange) in material 3 (blue). The short arrows on either side of the interface between two materials denote the spherical electromagnetic waves \( U(M \text{ and } N \text{ waves}) \). \( U^{(i)}_{lm} \) is vector spherical wave functions of order \((l, m)\), and superscript \((p)\) refers to the radial behavior of the waves. \( k_i \) is wavenumber in medium \( i \), \( R_{ij,l} \) and \( T_{ij} \) are the Mie reflection and transmission coefficients due to spherical electromagnetic waves \( U \) from medium \( i \) to medium \( j \), respectively.

\[
T_{rr}(\omega) = \Re \operatorname{Tr} \int_{S_1} dr \oint_{S_2} dr' \frac{\omega^2}{c^2} \left[ \hat{n}_2 \times \mu_2 \overline{G}_e(\tilde{r}, r) \right] \cdot \left[ \hat{n}_1 \times \varepsilon_1^{-1} \overline{G}_m(r, \tilde{r}) \right] + \left[ \hat{n}_2 \times \overline{G}_E(\tilde{r}, r) \right] \cdot \left[ \hat{n}_1 \times \overline{G}_E(r, \tilde{r}) \right] \tag{7}
\]

where \( \Re \) stands for the real part, superscript \(^*\) denotes the complex conjugate, and operator trace \( \operatorname{Tr}(\overline{A}) = \sum_{p=1}^{3} A_{pp} \).

respectively. Stress tensors \( \overline{\sigma}_e \) and \( \overline{\sigma}_m \) are given by [34]

\[
\overline{\sigma}_e(\tilde{r}) = \varepsilon_o \left[ \langle \mathbf{E}(\tilde{r}, t) \mathbf{E}(\tilde{r}, t) \rangle - \frac{1}{2} \overline{I}(\langle \mathbf{E}^2(\tilde{r}, t) \rangle) \right] \tag{8a}
\]

\[
\overline{\sigma}_m(\tilde{r}) = \mu_o \left[ \langle \mathbf{H}(\tilde{r}, t) \mathbf{H}(\tilde{r}, t) \rangle - \frac{1}{2} \overline{I}(\langle \mathbf{H}^2(\tilde{r}, t) \rangle) \right], \tag{8b}
\]

B. van der Waals stress for radiative momentum transfer

Radiative momentum transfer arising from the fluctuations of electromagnetic fields is responsible for the van der Waals pressure, which can be determined from the electromagnetic stress tensor, \( \overline{\sigma} = \overline{\sigma}_e + \overline{\sigma}_m \), where \( \overline{\sigma}_e \) and \( \overline{\sigma}_m \) are the electric and magnetic field contributions
and magnetic field components can be written as [37]

\[
\langle E_i,\hat{r},\omega\rangle E_j^*(\hat{r},\omega) = \frac{2\omega}{\pi} \int_{0}^{\infty} d\omega \epsilon(\omega) \mu(\omega) G_{e,ij}(\omega, T)
\]

where \( G_{e,ij}(\omega, T) \) is the dyadic Green’s function in an infinite homogeneous medium, and \( (\omega+i\xi_n) = \frac{2\pi k_B T}{h} \sum_{n=0}^{\infty} f(i\xi_n) \). Indicates that the \( n = 0 \) term is multiplied by \( 1/2 \) [66].

The expressions for \( \overline{G}_e^{(sc)}(r, \hat{r}) \) when \( r, \hat{r} \in V_2 \) (Fig. 1a) and \( r, \hat{r} \in V_1 \) (Fig. 1b), respectively, are given by

\[
\overline{G}_e^{(sc)}(r, \hat{r}) = ik_1 \sum_{m=1-\frac{i\xi_n}{\omega}}^{i\xi_n} (-1)^m \left[ R_{11,l}^{(M)} M_{l,m}^{(1)} (k_1 r) M_{l,-m}^{(1)} (k_1 \hat{r}) + R_{11,l}^{(N)} N_{l,m}^{(1)} (k_1 r) N_{l,-m}^{(1)} (k_1 \hat{r}) \right]
\]

Where \( R_{j,l}^{(M)} \) is the Mie reflection coefficient due to the source in region \( i \) to the observation in region \( j \) due to \( U = M, N \) waves. When \( |r| > |\hat{r}| \), \( k_1 = \omega \sqrt{\epsilon(\omega)\mu(\omega)} / c \) is the wavenumber in region \( i \) \( (i = 1, 2, 3) \), \( M_{l,m}^{(p)}(k_1 r) \) and \( N_{l,m}^{(p)}(k_1 r) \) are spherical wave functions of order \( (l, m) \), and superscript \( (p) \) refers to the radial behavior of the waves, given by [67]

\[
M_{l,m}^{(p)}(k_1 r) = \frac{z_l^{(p)}(k_1 r)}{\sqrt{l(l+1)}} \left( \frac{\partial}{\partial \theta} \right) \left( \frac{i m Y_{l,m}}{\sin \theta} \right)
\]

\[
N_{l,m}^{(p)}(k_1 r) = \frac{z_l^{(p)}(k_1 r)}{k_1 r \sqrt{l(l+1)}} \left( \frac{\partial}{\partial \theta} \right) \left( \frac{i m Y_{l,m}}{\sin \theta} \right)
\]

For superscript \( p = 1 \), both \( M \) and \( N \) waves are regular spherical waves and \( z_l^{(1)} \) is the spherical Bessel function of first kind of order \( l \). For superscript \( p = 3 \), both \( M \) and \( N \) waves are outgoing spherical waves and \( z_l^{(3)} \) is the spherical Hankel function of first kind of order \( l \). \( z_l^{(3)} \) is first derivative of Bessel (Hankel) function, defined as \( x_l^{(3)}(x) = \frac{d}{dx} \left[ x_l^{(3)}(x) \right] \). \( Y_{l,m} \) is the spherical harmonic of order \( (l, m) \).
III. RESULTS AND DISCUSSION

The spherical configurations of interest in this paper are shown in Fig. 1. To determine the generalized transmissivity for radiative energy transport (Eq. 7) and van der Waals stress (Eq. 10) for these geometries, we need to find the corresponding electric and/or magnetic dyadic Green’s functions, which are expressed in terms of the Mie reflection coefficients. Here, we list boundary conditions of electromagnetic fields (see Eqs. A1 - A6 in Appendix A for further details) to be used to calculate the Mie reflection and transmission coefficients (see Eqs. B1a - B2b in Appendix B for further details) for the four cases: (a) a sphere of radius \( r \), (b) a bubble of radius \( r \), (c) a spherical shell of interior and exterior radii \( r_1 \) and \( r_2 \), and (d) a sphere of radius \( r \) with a coating of thickness \( r_2 - r_1 \) (the same as case (c) in mathematics).

A. Spectral emissivity of a single/coated sphere

Now, the Mie scattering coefficients and dyadic Green’s functions of a sphere are known. Substituting Eq. B2a - Eq. B2b, or Eqs. B4a - B4d, Eq. 11a and Eq. 11b into Eq. 7 yields the transmissivity between a single sphere Eq. B2b, or Eqs. B4a - B4d, Eq. 11a and Eq. 11b into functions of a sphere are known. Substituting Eq. B2a - B2b in Appendix B for further details) for the four cases: (a) a sphere of radius \( r \), (b) a bubble of radius \( r \), (c) a spherical shell of interior and exterior radii \( r_1 \) and \( r_2 \), and (d) a sphere of radius \( r \) with a coating of thickness \( r_2 - r_1 \) (the same as case (c) in mathematics).

and when radius \( r = 0.5 \mu m \) is close to the absorption depth \( (d_{abs} = c/2\omega\kappa) \) of SiC, the emission spectrum (red curve) displays two sharp peaks at wavelengths 0.098 eV and 0.114 eV, respectively. These two emission peaks are exactly corresponding the frequencies at which the dielectric function reaches its minimum value. Other explanation to understand the existence of these sharp peaks in emission spectrum is the absorption depth of electromagnetic waves in comparison to the size of the object. When the radii of spheres become comparable to the absorption depth at mode wavelengths, at which the dielectric functions become negative or very close to zero, the reflection and transmission of a micro/nano-sized sphere are weakened, and the emission is enhanced at those characteristic wavelengths due to multiple reflections and Mie scattering within the object. The emission spectrum of a coated SiC sphere (magenta curve) of radius \( r_1 = 0.5 \mu m \) and a Boron Nitride (BN) layer of thickness \( r_2 - r_1 = 0.1 \mu m \) at room temperature \( T = 300 K \).
than the thermal wavelength as well as the penetration depth of electromagnetic waves, most of the waves get reflected or transmitted by the object, like “leakage” to the ambient [1], so the emission spectrum doesn’t depend on the wavelength-dependent dielectric function nor the object size strongly.

B. van der Waals surface energy of a spherical bubble

Substituting the scattered part of spherical dyadic Green’s functions Eq. 11a and Eq. 11b into Eq. 10, it yields the $r \times r$ component of the stress tensor at the interior vacuum-medium interface within a bubble, i.e., at $r \approx r + \delta$ as $\delta \to 0$, which can be written as

$$S_{rr}(r) = \Re \int_{0}^{\infty} \frac{d \omega}{4\pi c^3} \coth \left( \frac{\hbar \omega}{2k_B T} \right) \sum_{l=0}^{\infty} (2l + 1) \left( R^{(M)}_{11,l} + R^{(N)}_{11,l} \right) \left[ \left( 1 - \frac{l(l + 1)}{k_l r^2} \right) \xi_i^{(1/2)}(k_l r) + \xi_i^{(1/2)}(k_l r) \right]$$

(14)

Let the hydrostatic pressures in the vacuum and medium out of the bubble be $p_V$ and $p_M$ respectively. Balance of forces at the interface yields a modified Young-Laplace equation, and the pressure change across the interface of a bubble can be expressed below,

$$\Delta p = p_V - p_M = S_{rr}(r) + \frac{2\sigma_\infty(T)}{r}$$

(15a)

$$\Rightarrow \sigma(r, T) \approx \sigma_\infty(T) + \frac{r}{2}S_{rr}(r)$$

(15b)

where $\sigma_\infty$ is temperature dependent surface tension. Manipulation of Eq. 15a gives rise to a temperature as well as size dependent surface energy $\sigma(r, T)$ of a bubble of radius $r$ at temperature $T$ in Eq. 15b.

The stress tensor $S_{rr}(r)$ and surface stress due to surface tension $2\sigma_\infty/r$ are plotted for water and heptane in Fig. 3. The thermophysical property data can be obtained through the NIST Chemistry WebBook [68]. It can be seen that the $r \times r$ component of the van der Waals stress obeys a $r^{-3}$ rule, while the stress due to surface tension $2\sigma_\infty/r$ follows $r^{-1}$. The interaction of two curves implies a critical radius $r_{cr}$ which is defined to be such that $S_{rr} = 2\sigma_\infty/r$. As $r \gg r_{cr}$, surface tension dominates the surface energy of a bubble in the process of homogeneous nucleation, whereas for $r < r_{cr}$, van der Waals stress plays a significant role in surface energy of a nano-sized bubble. It can be found that the critical radius is $r_{cr} \approx 0.8$ nm for both water and heptane. Eq. 15b shows that surface energy $\sigma(r, T) \approx rS_{rr}(r)/2$ when $r \ll r_{cr}$, and $\sigma(r, T) \approx \sigma_\infty(T)$ when $r \gg r_{cr}$.

IV. CONCLUSION

Fluctuations of electromagnetic fields lead to radiative energy and momentum transfer between objects. They can be described by the cross-spectral densities of the electromagnetic fields, which are expressed in terms of the dyadic Green’s functions of the vector Helmholtz equation. The radiative energy and momentum transfer between planar objects have been studied during the past decades, while that between other geometries, such as spherical or cylindrical shapes, have not been investigated well. The proximity approximation and/or modified proximity approximation [69, 70] is one commonly used numerical approach to probe the near-field thermal radiation and fluctuation-induced van der Waals pressure between curved surface, but its validity depends strongly on the configurations and sizes of objects.

In this paper, we apply fluctuational electrodynamics directly to evaluate spectral emissivity of thermal radiation and van der Waals contribution to surface energy for various spherical shapes, such as a sphere, a bubble, a spherical shell and a coated sphere, in a homogeneous and isotropic medium. The dyadic Green’s function formalism of thermal radiative transfer and van der Waals stress for different spherical configurations have been developed. We have shown the size dependence and wavelength selectivity of emission spectrum and surface energy of the micro/nanoscale single and coated spheres for small radii. The spectral emissivity of sharp peaks can be observed at wavelengths corresponding to the characteristics of the material’s refractive index, and improved as the size of object decreases. van der Waals contribution dominates the surface energy when size of object is reduced to a nanoscopic length scale. The study of fluctuation-induced radiative energy and momentum transfer for spherical shapes has great applications in the nanoscale engineering, e.g., nanobeads, nanoparticle-nanofiber composites and multilayer-coated spherical shells. It deserves further investigation on the study of enhanced wavelength selectivity of radiative
thermal properties of nano-sized particles and the elec-
 tromagnetic effect of van der Waals contribution to the
 formation of bubbles in the phase change heat transfer
 in future.

 College of Engineering at the University of Rhode Island.

Appendix A: Boundary conditions of electromagnetic fields for four spherical cases

The boundary conditions of electromagnetic fields are listed below for the four cases: (a) a sphere of radius \( r \), (b) a bubble of radius \( r \), (c) a spherical shell of interior and exterior radii \( r_1 \) and \( r_2 \), and (d) a sphere of radius \( r_1 \) with a coating of thickness \( r_2 - r_1 \).

Case (a): A sphere with a radius of \( r_+ = r + \delta \) (\( \delta \to 0 \)). Thermal sources are outside the sphere, that is \( r \in V_2 \). The boundary conditions are given by

\[
\begin{align*}
\mu_2 z_1^{(1)}(k_2r) + R_{21}^{(M)} \mu_2 z_3^{(3)}(k_2r) &= T_{21}^{(M)} \mu_1 z_1^{(1)}(k_1r) \\
2 \xi_1^{(1)}(k_2r) + R_{21}^{(M)} \xi_3^{(3)}(k_2r) &= T_{21}^{(M)} \xi_1^{(1)}(k_1r)
\end{align*}
\]

(A1)

Case (b): A bubble with a radius of \( r_- = r - \delta \) (\( \delta \to 0 \)). Thermal sources are inside the bubble, that is \( r \in V_1 \). The boundary conditions are given by

\[
\begin{align*}
\mu_1 z_1^{(3)}(k_1r) + R_{11}^{(M)} \mu_1 z_1^{(1)}(k_1r) &= T_{12}^{(M)} \mu_2 z_3^{(3)}(k_2r) \\
2 \xi_1^{(3)}(k_1r) + R_{11}^{(M)} \xi_1^{(1)}(k_1r) &= T_{12}^{(M)} \xi_1^{(3)}(k_2r)
\end{align*}
\]

(A2)

Case (c): A spherical shell with an interior radius \( r_1 \) and an exterior radius \( r_2 \). (or Case (d): A sphere with a radius \( r_1 \) coated with a thin film of thickness \( r_2 - r_1 \). If thermal sources are in material 1 \( (r \in V_1) \), the boundary conditions at \( r = r_1 \) are given by

\[
\begin{align*}
\mu_1 z_1^{(3)}(k_1r_1) + R_{11}^{(M)} \mu_1 z_1^{(1)}(k_1r_1) &= R_{12}^{(M)} \mu_2 z_3^{(3)}(k_2r_1) + R_{12}^{(M)} \mu_2 z_3^{(1)}(k_2r_1) \\
\xi_1^{(3)}(k_1r_1) + R_{11}^{(M)} \xi_1^{(1)}(k_1r_1) &= R_{12}^{(M)} \xi_3^{(3)}(k_2r_1) + R_{12}^{(M)} \xi_3^{(1)}(k_2r_1)
\end{align*}
\]

(A3)

and the boundary conditions at \( r = r_2 \) are given by

\[
\begin{align*}
R_{12}^{(M)} \mu_2 z_3^{(3)}(k_2r_2) + R_{12}^{(M)} \mu_2 z_3^{(1)}(k_2r_2) &= T_{23}^{(M)} \mu_3 z_3^{(3)}(k_3r_2) \\
R_{12}^{(M)} \xi_3^{(3)}(k_2r_2) + R_{12}^{(M)} \xi_3^{(1)}(k_2r_2) &= T_{23}^{(M)} \xi_3^{(3)}(k_3r_2)
\end{align*}
\]

(A4)

And, if thermal sources are in material 3 \( (r \in V_3) \), the boundary conditions at \( r = r_2 \) are given by

\[
\begin{align*}
\mu_3 z_1^{(3)}(k_3r_2) + R_{33}^{(M)} \mu_3 z_1^{(1)}(k_3r_2) &= R_{32}^{(M)} \mu_2 z_3^{(3)}(k_2r_2) + R_{32}^{(M)} \mu_2 z_3^{(1)}(k_2r_2) \\
\xi_3^{(3)}(k_3r_2) + R_{33}^{(M)} \xi_3^{(1)}(k_3r_2) &= R_{32}^{(M)} \xi_3^{(3)}(k_2r_2) + R_{32}^{(M)} \xi_3^{(1)}(k_2r_2)
\end{align*}
\]

(A5)

and the boundary conditions at \( r = r_1 \) are given by

\[
\begin{align*}
R_{32}^{(M)} \mu_2 z_3^{(3)}(k_2r_1) + R_{32}^{(M)} \mu_2 z_3^{(1)}(k_2r_1) &= T_{21}^{(M)} \mu_1 z_1^{(3)}(k_1r_1) \\
R_{32}^{(M)} \xi_2^{(3)}(k_2r_1) + R_{32}^{(M)} \xi_2^{(1)}(k_2r_1) &= T_{21}^{(M)} \xi_1^{(3)}(k_1r_1)
\end{align*}
\]

(A6)

Here, \( R_{ij,l}^{(U)} \) and \( T_{ij}^{(U)} \) are the Mie reflection and transmission coefficients due to \( U(= M, N) \) waves from region \( i \) to region \( j \), respectively.
Appendix B: Mie reflection and transmission coefficients

For example, the Mie coefficients due to $M$ waves $R_{11,l}^{(M)}$ and $T_{12,l}^{(M)}$ in Case (a) can be obtained from Eq. A1 as

$$R_{22,l}^{(M)} = \frac{k_2 \xi_1^{(1)}(k_2 a) - k_1 \xi_1^{(1)}(k_1 r)}{\mu_2 z_1^{(1)}(k_2 r) - \mu_1 z_1^{(1)}(k_1 r)} \frac{z_1^{(1)}(k_2 r)}{z_1^{(3)}(k_2 r)}$$

(B1a)

and the Mie coefficients due to $M$ waves $R_{11,l}^{(M)}$ and $T_{12,l}^{(M)}$ in Case (b) can be obtained from Eq. A2 as

$$R_{22,l}^{(M)} = \frac{k_2 \xi_1^{(3)}(k_1 r) - k_1 \xi_1^{(3)}(k_2 r)}{\mu_2 z_1^{(1)}(k_1 r) - \mu_1 z_1^{(3)}(k_2 r)} \frac{z_1^{(3)}(k_1 r)}{z_1^{(1)}(k_1 r)}$$

(B2a)

$$T_{21,l}^{(M)} = \frac{\mu_2}{\mu_1} \left( \frac{y_0^{(1)}(k_2 r)}{y_0^{(1)}(k_1 r)} + R_{22,l}^{(M)} \frac{y_0^{(3)}(k_2 r)}{y_0^{(1)}(k_1 r)} \right)$$

(B1b)

$$T_{12,l}^{(M)} = \frac{\mu_1}{\mu_2} \left( \frac{y_0^{(3)}(k_1 r)}{y_0^{(3)}(k_2 r)} + R_{11,l}^{(M)} \frac{y_0^{(3)}(k_1 r)}{y_0^{(3)}(k_2 r)} \right)$$

(B2b)

The Mie reflection and transmission coefficients due to $M$ waves in Cases (c) and (d) can be obtained by solving Eqs. A3 - A6. If thermal sources in material 1 ($r \in V_1$), Eq. A3 and Eq. A4 can be rewritten as

$$\begin{bmatrix}
-\mu_1 z_1^{(1)}(k_1 r_1) & \mu_2 z_1^{(3)}(k_2 r_1) & \mu_2 z_1^{(1)}(k_2 r_1) & 0 \\
-k_1 \xi_1^{(1)}(k_1 r_1) & k_2 \xi_1^{(3)}(k_2 r_1) & k_2 \xi_1^{(1)}(k_2 r_1) & 0 \\
0 & \mu_2 z_1^{(3)}(k_2 r_2) & \mu_2 z_1^{(1)}(k_2 r_2) & -\mu_3 z_1^{(3)}(k_3 r_2) \\
0 & k_2 \xi_1^{(3)}(k_2 r_2) & k_2 \xi_1^{(1)}(k_2 r_2) & -k_3 \xi_1^{(3)}(k_3 r_2)
\end{bmatrix}
\begin{bmatrix}
R_{11,l}^{(M)} \\
R_{12,l}^{(M)} \\
R_{22,l}^{(M)} \\
T_{23,l}^{(M)}
\end{bmatrix}
= \begin{bmatrix}
\mu_1 z_1^{(3)}(k_1 r_1) \\
\mu_2 z_1^{(3)}(k_1 r_1) \\
\mu_3 z_1^{(3)}(k_1 r_1) \\
0
\end{bmatrix}$$

(B3)

and, it leads to

$$R_{11,l}^{(M)} = -NCJE + MCKE + IDNE - DLKE + ANGJ - AMGK - IAHN + ALHK - NCJF + NGBJ - BMGK - IBHN + BHLK + FMCK + IFDN + FDLK$$

(B4a)

$$R_{12,l}^{(M)} = -(-EB + AF)(NJ - MK)$$

(B4b)

$$R_{22,l}^{(M)} = -(-IN + KL)(-EB + AF)$$

(B4c)

$$T_{23,l}^{(M)} = -(-IM + JL)(-EB + AF)$$

(B4d)

where,

$$A = \mu_1 z_1^{(3)}(k_1 r_1), B = \mu_1 z_1^{(1)}(k_1 r_1), C = \mu_2 z_1^{(3)}(k_2 r_1), D = \mu_2 z_1^{(1)}(k_2 r_1),$$

$$E = k_1 \xi_1^{(3)}(k_1 r_1), F = k_1 \xi_1^{(1)}(k_1 r_1), G = k_2 \xi_1^{(3)}(k_2 r_1), H = k_2 \xi_1^{(1)}(k_2 r_1)$$

(B5a)

(B5b)
\[ I = \mu_2 z^{(3)}_i(k_2 r_2), J = \mu_2 z^{(1)}_i(k_2 r_2), K = \mu_3 z^{(3)}_i(k_3 r_2), \] (B5c)

\[ L = k_2 \xi^{(3)}_i(k_2 r_2), M = k_2 \xi^{(1)}_i(k_2 r_2), N = k_3 \xi^{(3)}_i(k_3 r_2), \] (B5d)

If thermal sources in material \( r \in V_3 \), Eq. A5 and Eq. A6 can be rewritten as

\[
\begin{bmatrix}
-\mu_3 z^{(3)}_i(k_3 r_2) & \mu_2 z^{(1)}_i(k_2 r_2) & \mu_2 z^{(3)}_i(k_2 r_2) & 0 \\
-k_3 \xi^{(3)}_i(k_3 r_2) & k_2 \xi^{(1)}_i(k_2 r_2) & k_2 \xi^{(3)}_i(k_2 r_2) & 0 \\
0 & \mu_2 z^{(1)}_i(k_2 r_1) & \mu_2 z^{(3)}_i(k_2 r_1) & -\mu_1 z^{(1)}_i(k_1 r_1) \\
0 & k_2 \xi^{(1)}_i(k_2 r_1) & k_2 \xi^{(3)}_i(k_2 r_1) & -k_1 \xi^{(1)}_i(k_1 r_1)
\end{bmatrix}
\begin{bmatrix}
R_{33,i}^{(M)} \\
R_{32,i}^{(M)} \\
R_{32,i}^{(M)} \\
T_{21,i}^{(M)}
\end{bmatrix}
= \begin{bmatrix}
\mu_3 z^{(1)}_i(k_3 r_2) \\
0 \\
0 \\
0
\end{bmatrix}
\] (B6)

and, it leads to

\[
R_{33,i}^{(M)} = -\frac{\mu_3 z^{(3)}_i(k_3 r_2) + \mu_2 z^{(1)}_i(k_2 r_2) + \mu_2 z^{(3)}_i(k_2 r_2) + 0}{-NCJ + MCKE + IDNE - DLKE + ANGJ - AMGK - IAHN + ALHK - NCFJ + NGBJ - BMGK - IBHN} + BHLK + FMC + IFDN + FDLK
\] (B7a)

\[
R_{32,i}^{(M)} = -\frac{(-EB + AF)(NJ - MK)}{-NCJ + NGBJ - BMGK - IBHN + BHLK + FMC + IFDN - FDLK}
\] (B7b)

\[
\frac{z^{(M)}}{R_{32,i}} = -\frac{(-IN + KL)(-EB + AF)}{-NCJ + NGBJ - BMGK - IBHN + BHLK + FMC + IFDN - FDLK}
\] (B7c)

\[
T_{21,i}^{(M)} = -\frac{(-IM + JL)(-EB + AF)}{-NCJ + NGBJ - BMGK - IBHN + BHLK + FMC + IFDN - FDLK}
\] (B7d)

where,

\[
A = \mu_3 z^{(1)}_i(k_3 r_2), B = \mu_3 z^{(3)}_i(k_3 r_2), C = \mu_2 z^{(1)}_i(k_2 r_2), D = \mu_2 z^{(3)}_i(k_2 r_2),
\] (B8a)

\[
E = k_3 \xi^{(1)}_i(k_3 r_2), F = k_3 \xi^{(3)}_i(k_3 r_2), G = k_2 \xi^{(1)}_i(k_2 r_2), H = k_2 \xi^{(3)}_i(k_2 r_2),
\] (B8b)

\[
I = \mu_2 z^{(1)}_i(k_2 r_1), J = \mu_2 z^{(3)}_i(k_2 r_1), K = \mu_1 z^{(1)}_i(k_1 r_1),
\] (B8c)

\[
L = k_2 \xi^{(1)}_i(k_2 r_1), M = k_2 \xi^{(3)}_i(k_2 r_1), N = k_1 \xi^{(1)}_i(k_1 r_1),
\] (B8d)

Similarly, the Mie coefficients due to \( N \) waves can be obtained by simply switching functions of \( z_i \) and \( \xi_i \) [67]. Substituting the Mie coefficients into Eqs. 11a and 11b yields the scattering parts of dyadic Green’s functions, and then they can be used to determine a generalized transmissivity for radiative energy transfer (Eq. 7) and an electromagnetic stress tensor (Eq. 10).
