Abstract The hybrid metric-Palatini $f(\mathcal{R})$ gravity is a recently devised approach to modified gravity in which it is added to the metric Ricci scalar $R$, in the Einstein-Hilbert Lagrangian, a function $f(\mathcal{R})$ of Palatini curvature scalar $\mathcal{R}$, which is constructed from an independent connection. These hybrid metric-Palatini gravity theories provide an alternative way to explain the current accelerating expansion without a dark energy matter component. If gravitation is to be described by a hybrid metric-Palatini $f(\mathcal{R})$ gravity theory there are a number of issues that ought to be examined in its context, including the question as to whether its equations allow homogeneous G"odel-type solutions, which necessarily leads to violation of causality. Here, to look further into the potentialities and difficulties of $f(\mathcal{R})$ theories, we examine whether they admit G"odel-type solutions for physically well-motivated matter source. We first show that under certain conditions on the matter sources the problem of finding out space-time homogeneous (ST-homogeneous) solutions in $f(\mathcal{R})$ theories reduces to the problem of determining solutions of Einstein’s field equations with a cosmological constant. Employing this far-reaching result, we determine a general ST-homogeneous G"odel-type solution whose matter source is a combination of a scalar with an electromagnetic fields plus a perfect fluid. This general G"odel-type solution contains special solutions in which the essential parameter $m^2$ can be $m^2 > 0$ hyperbolic family, $m = 0$ linear class, and $m^2 < 0$ trigonometric family, covering thus all classes of homogeneous G"odel-type spacetimes. This general solution also contains all previously known solutions as special cases. The bare existence of these G"odel-type solutions makes apparent that hybrid metric-Palatini $f(\mathcal{R})$ gravity does not remedy causal anomaly in the form of closed timelike curves that are permitted in general relativity.

1 Introduction

A number of cosmological observations coming from different sources, including the supernovae type Ia (SNe Ia) \cite{1,2,3}, the cosmic microwave background radiation (CMBR) \cite{4,5} and baryon acoustic oscillation (BAO) surveys \cite{6,7,8,9,10}, indicate that the Universe is presently expanding with an accelerating rate. The frameworks proposed to account for this observed accelerated expansion can be roughly grouped into two families. In the first, the underlying theory, general relativity (GR), is kept unchanged, and the so-called dark energy component is invoked. In this context, the simplest way to account for the accelerating expansion of the Universe is through the introduction of a cosmological constant, $\Lambda$, into Einstein’s field equations. This is completely consistent with the available observational data, but it faces difficulties such as the order of magnitude of the cosmological constant and its microphysical origin. In the second family, modifications of Einstein’s field equations are assumed as an alternative for explaining the accelerated expansion of the Universe is through the introduction of a cosmological constant, $\Lambda$, into Einstein’s field equations. This is completely consistent with the available observational data, but it faces difficulties such as the order of magnitude of the cosmological constant and its microphysical origin. In the second family, modifications of Einstein’s field equations are assumed as an alternative for explaining the accelerated expansion. This latter group includes, for example, generalized theories of gravity based upon modifications of the Einstein-Hilbert action by taking nonlinear functions, $f(R)$, of the Ricci scalar $R$ or other curvature invariants (for reviews see Refs. \cite{11,12,13,14,15,16}).

In dealing with $f(R)$ gravity theories two different variational approaches, which give rise to different dynamics, have often been considered in the literature \cite{11,12,13,14,15,16}. In the so-called metric formalism the connection is assumed to be Levi-Civita, therefore defined by the met-
ric. In the Palatini formalism the metric and the connection are treated as independent fields, and it is assumed that the matter fields do not couple with the independent connections. Although these approaches have been invoked as possible ways to satisfactorily deal with the observed accelerated expansion of the Universe, it has been pointed out that $f(R)$ gravity theories can face relevant difficulties, including the evolution of cosmological perturbations and local gravity constraints (see, for example, Refs. [19, 17, 18, 20, 14, 21, 22]).

These undesirable features have motivated a recent approach to modified $f(R)$ theories of gravity, which can be employed as a possible way to handle the observed late-time cosmic acceleration, and also circumvent some difficulties that arise in the framework of $f(R)$ theories in both formalisms. The hybrid metric-Palatini $f(\mathcal{R})$ gravity is a recently devised approach to such modified theories, in which it is added to the ordinary Ricci scalar $R$, in the Einstein-Hilbert Lagrangian, a function, $f$, of $R$, of Palatini curvature scalar $\mathcal{R}$, which is constructed from the independent connection $\Gamma^\rho_{\mu\nu}$ [23]. These hybrid metric-Palatini gravity theories appears to suitably unify the description of the late-time cosmic acceleration with the local solar system constraints [23, 24]. Some of the astrophysical and cosmological implications of hybrid metric-Palatini gravity have been examined in a number of papers [25, 26, 27, 28, 29]. Wormhole solutions, Einstein static universe, linear perturbations, the Cauchy problem, dynamical system analysis and a brane model have been discussed, respectively, in the references [30, 31, 22, 33, 34, 35]. Other important matters such as Noether symmetries [36] and the thermodynamic behavior [37] have also been recently considered. For an introduction to hybrid metric-Palatini $f(\mathcal{R})$ gravity and a detailed list of related references, we refer the reader to the recent review article [28].

In general relativity (GR) the space-times have locally the same causal structure of the flat space-time of special relativity since the space-times of GR are locally Minkowskian. On nonlocal scale, however, significant differences may arise since the general relativity field equations do no provide nonlocal constraints on the underlying space-times. Indeed, it has long been known that there are solutions to Einstein’s field equations that present nonlocal causal anomalies in the form of closed time-like curves (see, for example, Refs. [38, 39, 40, 41, 42, 43]).

The renowned model found by Gödel [44] is the best known example of a solution to the Einstein’s equations, with a physically well-motivated source, that makes it appear that GR permits solutions with closed time-like world lines, regardless of its local Lorentzian character that ensures locally an inherited regular chronology and therefore the local validation of the causality principle. The Gödel model is a solution of Einstein’s equations with cosmological constant $\Lambda$ for dust of density $\rho$, but it can also be viewed as perfect-fluid solution with equation of state $p = \rho$ with no cosmological constant term. Owing to its unexpected properties, Gödel’s solution has a recognizable importance and has motivated a considerable number of investigations on rotating G"odel-type models as well as on causal anomalies in the context of general relativity (see, e.g. Refs. [38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54] and other gravity theories [55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79]. In two recent papers, we have also examined G"odel-type models and the violation of causality problem for $f(R)$ gravity in both the metric and Palatini variational approaches [71, 72], extending therefore the results of Refs. [80] and [81].

If gravitation is to be described by hybrid metric-Palatini $f(\mathcal{R})$ gravity theory there are a number of issues that ought to be reexamined in its context, including its consistence with the recent detection of gravitational wave [82] and the question as to whether these gravity theories allow G"odel-type solutions, which necessarily lead to closed timelike curves, or would remedy this causal pathology by ruling out this type of solutions, which are permitted in general relativity.

In this article, to proceed further with the investigations on the potentialities, difficulties and limitations of $f(\mathcal{R})$, we undertake this question by examining whether the $f(\mathcal{R})$ gravity theories admit homogeneous G"odel-type solutions for a combination of physically well-motivated matter sources. To this end, we first examine the general problem of finding out ST-homogeneous solutions in hybrid metric-Palatini $f(\mathcal{R})$ gravity for matter sources with constant trace $T$ (scalar) of the energy-momentum tensor, and show that it reduces to the problem of determining ST-homogeneous solutions of Einstein’s field equations with a cosmological constant determined by $f(\mathcal{R})$ and its first derivative $f'(\mathcal{R})$. Employing this far-reaching result, we determine a general ST-homogeneous G"odel-type whose matter source is a combination of a scalar with an electromagnetic fields plus a perfect fluid. This general G"odel-type solution contains special solutions in which the essential parameter $m^2$ defines any one of the possible classified families homogeneous G"odel-type solutions, namely $m^2 > 0$ hyperbolic family, $m = 0$ linear class, and $m^2 < 0$ trigonometric family. This general homogeneous G"odel-type solution also contains previously known solutions as special cases. There emerges from one of the particular solution of the hyperbolic family that every perfect-fluid G"odel-type solution of any $f(\mathcal{R})$ gravity with density $\rho$ and pressure $p$ and satisfying the weak en-
ergy conditions $\rho > 0$ and $\rho + p \geq 0$ is necessarily isometric to the Gödel geometry.\footnote{This extends to the context of $f(\mathcal{S})$ gravity a theorem which states that every perfect-fluid Gödel-type solution of Einstein’s equations is necessarily isometric to the Gödel spacetime \cite{53}.}

The bare existence of these noncausal Gödel-type solutions makes apparent that hybrid metric-Palatini $f(\mathcal{S})$ gravity does not remedy causal anomaly in the form of closed timelike curves that are permitted in general relativity.

The structure of the paper is as follows. In Section 2 we give a brief account of the hybrid metric-Palatini $f(\mathcal{S})$ gravity theories. In Section 3 we present the basic properties of homogenous Gödel-type geometries and a study of the existence of closed time-like curves in all ST-homogeneous Gödel-type metrics. In Section 4 we first examine the problem of finding out ST-homogeneous solutions in $f(\mathcal{S})$ gravity whose trace $T$ of the energy-momentum tensor of the matter source is constant, and show that in such cases the problem reduces to that of finding out solutions of Einstein’s field equations with a cosmological constant. We then show a brief account of the hybrid metric-Palatini gravity theories admit ST-homogeneous Gödel-type solutions, in Section 4, to the hybrid metric-Palatini gravity a theorem which states that the hybrid metric-Palatini gravity theories admit closed time-like curves that are permitted in general relativity.

2 Hybrid metric-Palatini gravity

The action that defines a hybrid metric-Palatini gravity is given by

$$ S = \frac{1}{2\kappa^2} \int d^4x \sqrt{-g} \left[ R + f(\mathcal{S}) + \mathcal{L}_m \right],$$

(1)

where $\kappa^2 = 8\pi G$, $g$ is the determinant of the metric tensor $g_{\mu\nu}$, $R$ is the Ricci scalar associated to the Levi-Civita connection of the metric $g_{\mu\nu}$, $\mathcal{L}_m$ is the Lagrangian density for the matter fields, and the extra term $f(\mathcal{S})$ is a function of Palatini curvature scalar $\mathcal{S}$, which depends on the metric and on an independent connection $\Gamma_{\mu\nu}^\rho$ through

$$ \mathcal{S} \equiv g^{\mu\nu} \mathcal{R}_{\mu\nu} = g^{\mu\nu} \left( \partial_\rho \Gamma_{\mu\nu}^\rho - \partial_\nu \Gamma_{\mu\rho}^\rho + \Gamma_{\rho\lambda}^\rho \Gamma_{\mu\lambda}^\nu - \Gamma_{\mu\lambda}^\nu \Gamma_{\rho\lambda}^\rho \right).$$

(2)

The variation of the action (1) with respect to the metric gives the field equations

$$ G_{\mu\nu} + F(\mathcal{S}) \mathcal{R}_{\mu\nu} - \frac{f(\mathcal{S})}{2} g_{\mu\nu} = \kappa^2 T_{\mu\nu},$$

(3)

where $G_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R$ and $R_{\mu\nu}$ are, respectively, Einstein and Ricci tensor associated with the Levi-Civita connection of $g_{\mu\nu}$, $F(\mathcal{S}) \equiv df/d\mathcal{S}$, $T_{\mu\nu} =$ \(\frac{-2}{\sqrt{-g}} \delta (\sqrt{-g} \mathcal{L}_m) / \delta g^{\mu\nu}\) is the energy-momentum tensor of the matter fields.

The variation of the action (1) with respect to the independent connection $\Gamma_{\mu\nu}^\rho$ yields

$$ \nabla_\rho \left( \sqrt{-g} F(\mathcal{S}) g^{\mu\nu} \right) = 0,$$

(4)

where $\nabla_\rho$ denotes the covariant derivative associated with $\Gamma_{\mu\nu}^\rho$. If one defines a metric $h_{\mu\nu} = F(\mathcal{S}) g_{\mu\nu}$, it can be easily shown that Eq. (4) determines a Levi-Civita connection of $h_{\mu\nu}$, which in turn can be rewritten in terms of $g_{\mu\nu}$ and its Levi-Civita connection $\{ \Gamma_{\mu\nu}^\rho \}$ in the form

$$ \Gamma_{\mu\nu}^\rho = \left\{ \frac{\rho}{\mu\nu} \right\} + \frac{1}{2} \left( \delta_{\sigma}^\rho \partial_\nu + \delta_{\sigma}^\rho \partial_\mu - \delta_{\nu\mu} \delta^{\sigma\rho} \partial_\sigma \right) \ln F(\mathcal{S}).$$

(5)

Using now Eq. (5) one finds the relation between the two Ricci tensors, which is given by

$$ \mathcal{R}_{\mu\nu} = R_{\mu\nu} + \frac{3}{F^2} \partial_\mu F \partial_\nu F - \frac{1}{F^2} (\nabla_\mu \nabla_\nu + \frac{1}{2} g_{\mu\nu} \Box F),$$

(6)

where $\nabla_\mu$ denotes the covariant derivative associated to $\{ \Gamma_{\mu\nu}^\rho \}$.

Equation (5) in turn gives rise to the following relation between the two Ricci scalars:

$$ \mathcal{R} = R + \frac{3}{F^2} (\partial F)^2 - \frac{3}{F} \Box F,$$

(7)

where $(\partial F)^2 = g^{\alpha\beta} \partial_\alpha F \partial_\beta F$ and $\Box F = g^{\alpha\beta} \nabla_\alpha \nabla_\beta F$.

The Palatini curvature $\mathcal{S}$ can be obtained from the trace of the field Eq. (3), which yields

$$ F(\mathcal{S}) = -2 f(\mathcal{S}) = \kappa^2 T + R \equiv X.$$

(8)

This trace equation can be used to express $\mathcal{S}$ algebraically in terms of $X$ when the $f(\mathcal{S})$ is given as an analytic expression. Finally, we note that the variable $X$ measures the deviation from the general relativity trace equation $R = -\kappa^2 T$.

3 Homogeneous Gödel-type geometries

To make this work clear and to a certain extent self-contained, in this section we present the basic properties of homogenous Gödel-type geometries, which we use in the following sections. To this end, we first discuss the conditions for space-time homogeneity (ST-homogeneity) of these space-times, and present all non-isometric ST-homogeneous Gödel-type classes. These ST-homogeneity conditions along with the set of isometrically non-equivalent geometries are important in the determination of ST-homogeneous Gödel-type solutions, in Section 4, to the hybrid metric-Palatini $f(\mathcal{S})$ field equations. Second, we discuss the existence of closed time-like curves in the metrics of these classes. The existence of these non-causal curves are crucial to examine whether hybrid metric-Palatini $f(\mathcal{S})$ gravities allow violation of causality of Gödel-type.
3.1 Homogeneity and non-equivalent metrics

Gödel solution to the general relativity field equations is a particular member of the broad family of geometries whose general form in cylindrical coordinates, \((r, \phi, z)\), is given by \[81\]

\[\begin{align*}
\text{ds}^2 &= \left[dt + H(r)d\phi\right]^2 - D^2(r)d\phi^2 - dr^2 - dz^2.
\end{align*}\]  

(9)

The necessary and sufficient conditions for the Gödel-type metric \[9\] to be space-time homogeneous (ST-homogeneous) are given by \[81, 84\]:

\[H' \over D = 2\omega \quad \text{and} \quad D' \over D = m^2,\]  

(10)

where the prime denote derivative with respect \(r\), and the parameters \((\Omega, m)\) are constants such that \(\Omega^2 > 0\) and \(-\infty \leq m^2 \leq \infty\).

As a matter of fact, except for the case \(m^2 = 4\omega^2\) all locally ST-homogeneous Gödel-type space-times admit a group \(G_5\) of isometries acting transitively on the whole space-time \[84\]. The special case \(m^2 = 4\omega^2\) admits a \(G_7\) of isometries \[85, 84\].

The irreducible set of isometrically nonequivalent ST-homogeneous Gödel-type metrics can be obtained by integrating equations \[10\] and suitably eliminating nonessential integration constants. The final result is that ST-homogeneous Gödel-type geometries can be grouped in the following three classes \[81\]:

i. Hyperbolic, in which \(m^2 = \text{const} > 0\) and

\[H = \frac{4\omega}{m^2} \sinh^2\left(\frac{mr}{2}\right), \quad D = \frac{1}{m} \sinh(mr);\]  

(11)

ii. Linear, in which \(m = 0\) and

\[H = \omega r^2, \quad D = r,\]  

(12)

iii. Trigonometric, where \(m^2 = \text{const} = -\mu^2 < 0\) and

\[H = \frac{4\omega}{\mu^2} \sin^2\left(\frac{\mu r}{2}\right), \quad D = \frac{1}{\mu} \sin(\mu r).\]  

(13)

Thus, clearly all ST-homogeneous Gödel-type geometries are characterized by the two independent parameters \(m^2\) and \(\omega\) — identical pairs \((m^2, \omega^2)\) specify isometric space-times \[81, 85, 84\]. In this way, to determine whether hybrid metric-Palatini \(f(R)\) gravity allows Gödel-type solutions is to find out whether its field equations can be used to specify a pair of parameters \(m^2\) and \(\omega\) for a suitably chosen matter source.

\[\text{3.2 Closed time-like curves}\]

We begin by noting that the presence of a single closed time-like curve in a space-time is an unequivocal manifestation of violation of causality. However, a space-time may admit non-causal closed curves other than Gödel’s circles we discuss in this Section. To examine the existence of closed time-like curves in ST-homogeneous Gödel-type metrics we first rewrite the line element \[9\] as

\[\text{ds}^2 = dt^2 + 2H(r)dt d\phi - dr^2 - d\phi^2 - d\sigma^2,\]  

(14)

where \(G(r) = D^2 - H^2\). In this form it is easy to show that existence of closed time-like curves, which allows for violation of causality in homogeneous Gödel-type space-times, depends on the sign of the metric function \(G(r)\). Indeed, from Eq. \[14\] one has that the circles, hereafter called Gödel’s circles, defined by \(t, z, r = \text{const}\) become closed timelike curves whenever \(G(r) < 0\).

For the hyperbolic \((m^2 > 0)\) class of homogeneous Gödel-type metrics, from Eqs. \[11\] one has that

\[G(r) = \frac{4}{m^2} \sinh^2\left(\frac{mr}{2}\right) \left(1 - \frac{4\omega^2}{m^2}\right) \sinh^2\left(\frac{mr}{2}\right) + 1.\]  

(15)

Therefore for \(0 < m^2 < 4\omega^2\) there is a critical radius \(r_c\) defined by \(G(r) = 0\), which is given by

\[\sinh^2\frac{mr_c}{2} = \left[\frac{4\omega^2}{m^2} - 1\right]^{-1},\]  

(16)

such that for \(r < r_c\) one has \(G(r) > 0\), and for \(r > r_c\) one has \(G(r) < 0\). Thus, the circles \(t, z, r = \text{const}\) with \(r > r_c\) are closed timelike curves \[8\].

For linear class \((m = 0)\) of homogeneous Gödel-type space-times, from Eq. \[12\] one easily finds

\[G(r) = r^2 - r^4 \omega^2 = -r^2(\omega r - 1)(\omega r + 1).\]  

(17)

Thus, there is a critical radius, defined by \(G(r) = 0\), and given by \(r_c = 1/\omega\), such that for any radius \(r > r_c\) one has \(G(r) < 0\), and then the circles defined by \(t, z, r = \text{const}\) are closed timelike curves.

Finally for the trigonometric class \((m^2 = \text{const} = -\mu^2 < 0)\), from the metric functions given by Eq. \[13\] one finds

\[G(r) = \frac{4}{\mu^4} \sin^2\left(\frac{\mu r}{2}\right) \left[\mu^2 - (4\omega^2 + \mu^2) \sin^2\left(\frac{\mu r}{2}\right)\right],\]  

(18)

and therefore \(G(r)\) has an infinite sequence of zeros. Thus, in the section \(t, z, r = \text{const}\), there is an sequence of alternating causal \([G(r) > 0]\) and noncausal \([G(r) < 0]\) regions without

\[3\text{Gödel geometry is a solution of Einstein’s equations in general relativity, is indeed a particular case of the hyperbolic class of geometries in which }m^2 = 2\omega^2.\]
and with noncausal circles, depending on the value of \( r = \text{const} \) (For more details see the Appendix of Ref. [25]). In this way, if \( G(r) < 0 \) for a certain range of \( r (r_1 < r < r_2, \text{say}) \) noncausal Gödel’s circles exist, whereas for \( r \) in the next circular band \( r_2 < r < r_3 \) (say) for which \( G(r) > 0 \) no such closed timelike circles exist, and so on.

To close this section, we note that in this paper by noncausal and causal solutions we mean, respectively, solutions with and without violation of causality of Gödel-type, i.e., with and without Gödel’s circles.

### 4 Solutions in hybrid metric-Palatini gravity

The aim of this section is twofold. First, we examine the problem of finding out ST-homogeneous solutions in hybrid metric-Palatini \( f(\mathcal{R}) \) gravity whose trace \( T \) of the energy-momentum tensor of the matter source is constant. We show that in such cases the problem of finding out solutions in the hybrid metric-Palatini \( f(\mathcal{R}) \) gravity reduces to the problem of determining ST-homogeneous solutions of Einstein’s field equations with a cosmological constant constant by \( f(\mathcal{R}) \) and its first derivative \( F = f'(\mathcal{R}) \). Second, we examine whether hybrid metric-Palatini \( f(\mathcal{R}) \) field equations admit ST-homogeneous Gödel-type solutions for a combination of a scalar field with an electromagnetic field plus a perfect fluid.

#### 4.1 Field equations

We begin by noting that using equation (6) the field equations (3) of the hybrid metric-Palatini \( f(\mathcal{R}) \) gravity can be rewritten in the form

\[
G_{\mu\nu} = \kappa^2 T^\text{eff}_{\mu\nu} = \kappa^2 \left( T_{\mu\nu} + T^\text{\mathcal{R}}_{\mu\nu} \right),
\]

where

\[
\kappa^2 T^\text{\mathcal{R}}_{\mu\nu} = \frac{1}{2} \left[ f(\mathcal{R}) + \square F(\mathcal{R}) \right] g_{\mu\nu} - F(\mathcal{R}) R_{\mu\nu} + \nabla_\mu \nabla_\nu F(\mathcal{R}) - \frac{3}{2F(\mathcal{R})} \partial_\mu F(\mathcal{R}) \partial_\nu F(\mathcal{R}).
\]

In this context, an important constraint comes from the trace of the field equations (19), which can be written in the form

\[
R + \kappa^2 T = X = -\kappa^2 T^\text{\mathcal{R}},
\]

where from equation (20) one has

\[
\kappa^2 T^\text{\mathcal{R}} = 2f(\mathcal{R}) - RF(\mathcal{R}) + 3\square F(\mathcal{R}) - \frac{3}{2} \frac{\partial F(\mathcal{R})^2}{F(\mathcal{R})}.
\]

For ST-homogeneous spacetimes, which we are concerned with in this paper, one has that the Ricci scalar is necessarily constant. On the other hand, for matter sources whose trace of the energy-momentum \( T \) is also constant, which we focus in this paper, one has \( X = \text{const} = -\kappa^2 T^\text{\mathcal{R}} \).

In such cases, one can show that the field equations of the hybrid metric-Palatini gravity reduces to Einstein’s field equations with a cosmological constant.

To this end, we first examine the second term on the right hand side of equation (3) which gives the departures of the independent connection \( T^\rho_{\mu\nu} \) from Levi-Civita connection \( \Gamma^\rho_{\mu\nu} \). Clearly, each individual part of this second term in this equation is proportional to

\[
\partial_\mu \ln F(\mathcal{R}) = \frac{F'}{F} \partial_\mu F(\mathcal{R}) = \frac{1}{F} \partial_\mu F(\mathcal{R}).
\]

On the other hand, to calculate \( \partial_\mu F(\mathcal{R}) \) we note that from the trace equation (8) one has

\[
\partial_\mu F(\mathcal{R}) = \frac{\partial_\mu X}{[F(\mathcal{R}) - F(\mathcal{R})]}, \text{ which together with equation (23) furnishes}
\]

\[
\partial_\mu F(\mathcal{R}) = \frac{F'(\mathcal{R}) \partial_\mu X}{F(\mathcal{R}) - F(\mathcal{R})},
\]

provided that \( F'(\mathcal{R}) - F(\mathcal{R}) \neq 0 \). From equations (23) and (24) one has that for \( X = \text{const} \) the connection \( T^\rho_{\mu\nu} \) reduces to Levi-Civita connection \( \Gamma^\rho_{\mu\nu} \). Furthermore, from equations (6) and (7) one can easily show that

\[
\partial_\mu F(\mathcal{R}) = 0
\]

also ensures that \( F(\mathcal{R}) = \text{const} \). Hence, the field equations of the hybrid metric-Palatini gravity (3) reduce formally to field equations of \( f(R) \) theories in the metric formalism, which can clearly be rewritten in the form

\[
[1 + F(R)] G_{\mu\nu} - \frac{1}{2} \left[ f(R) - RF(R) \right] g_{\mu\nu} = \kappa^2 T_{\mu\nu},
\]

with associated trace equation

\[
RF(R) - 2f(R) = \kappa^2 T + R = \text{const}.
\]

However, for an explicitly given \( f(\mathcal{R}) \), solving the algebraic equation (26) one finds constant roots \( R \)'s. Thus, for each explicit root the field equations (25) can be rewritten in the form

\[
G_{\mu\nu} = \kappa^2 T_{\mu\nu} + \Lambda g_{\mu\nu},
\]

where

\[
\Lambda = \frac{f(R) - RF(R)}{2[1 + F(R)]} \quad \text{and} \quad \kappa^2 = \frac{\kappa^2}{1 + F(R)}.
\]

The trace equation becomes

\[
R + \kappa^2 T + 4\Lambda = 0.
\]

Clearly, the factor \([1 + F(R)]\) in equations (28) is a constant that simply rescales the units of \( \kappa^2 \) and the effective cosmological constant \( \Lambda \).

\( ^{4}\text{Clearly, different roots } R \text{ give rise to different rescales of } \kappa^2, \text{ and different effective cosmological constant } \Lambda.\)
4.2 Gödel-type solutions

In this section we discuss ST-homogeneous Gödel-type solutions in hybrid metric-Palatini gravity for well-motivated matter contents whose trace of the energy-momentum tensor is constant.

We begin by noting that the search for ST-homogeneous Gödel-type solutions to the hybrid metric-Palatini gravity field equations is greatly simplified if instead of using coordinates basis one uses a new basis given by the following set of linearly independent one-forms (tetrad frame) $\Theta^A$:

$$\theta^0 = dt + H(r)d\phi, \theta^1 = dr, \theta^2 = D(r)d\phi, \theta^3 = dz,$$  \hspace{1cm} (30)

relative to which the Gödel-type line element \( s^2 \) takes the local Lorentzian form

$$ds^2 = \eta_{AB} \theta^A \theta^B = (\theta^0)^2 - (\theta^1)^2 - (\theta^2)^2 - (\theta^3)^2.$$  \hspace{1cm} (31)

Here and in what follows capital letters are tetrad indices (or Lorentz frame indices) and run from 0 to 3. These Lorentz frame indices are raised and lowered with Lorentz matrices $\eta^{AB} = \delta_{AB}$ or $\eta_{AB} = \operatorname{diag}(1, -1, -1, -1)$, respectively.

In the tetrad frame (30) the nonvanishing components of the Ricci tensor, $R_{AB} = \eta^{CD} R_{CABD}$, are given by

$$R_{02} = \frac{1}{2} \left( \frac{H'}{D} \right)^2, R_{00} = \frac{1}{2} \left( \frac{H'}{D} \right)^2,$$  \hspace{1cm} (32)

$$R_{11} = R_{22} = \frac{1}{2} \left( \frac{H'}{D} \right)^2 - \frac{D''}{D},$$  \hspace{1cm} (33)

where the prime denotes derivative with respect to $r$. Since the Lorentz frame components of the Ricci tensor depend only on $H'/D$ and $D''/D$, from the ST-homogeneity conditions (10) one has that for all classes of ST-homogeneous Gödel-type metrics the frame components of the Ricci tensor are constant. Thus, the Ricci scalar is also constant and given by $R = \eta^{CD} R_{CD} = 2(m^2 - \omega^2)$.

In this Lorentzian basis the field equations (27) reduce to

$$G_{AB} = \kappa^2 T_{AB} + \Lambda \eta_{AB},$$  \hspace{1cm} (34)

where from equations (62) and (33) along with the conditions (10) one has that the only nonvanishing Lorentz frame components of the Einstein tensor $G_{AB}$ for ST-homogeneous Gödel-type metrics take the very simple form

$$G_{00} = 3\omega^2 - m^2, \quad G_{11} = G_{22} = \omega^2, \quad G_{33} = m^2 - \omega^2.$$  \hspace{1cm} (35)

4.2.1 Combined-fields general solution

In this section we take combination of scalar and electromagnetic fields with a perfect fluid as a matter source, and find a general ST-homogeneous Gödel-type solution, which contains a perfect fluid and a scalar field particular solutions, and whose essential parameter $m^2 > 0$ (hyperbolic family), $m = 0$ (linear class) or $m^2 < 0$ (trigonometric family) depending on the amplitude values of the matter components.

In the Lorentzian basis (30) the energy-momentum tensor of combined matter sources takes the form

$$T_{AB} = T_{AB}^{(M)} + T_{AB}^{(S)} + T_{AB}^{(EM)},$$  \hspace{1cm} (36)

where $T_{AB}^{(M)}$, $T_{AB}^{(S)}$ and $T_{AB}^{(EM)}$ are, respectively, the energy momentum tensors of a perfect fluid, a scalar field, and an electromagnetic field, which we discuss in what follows.

For a perfect fluid of density $\rho$ and pressure $p$, $T_{AB}^{(M)}$ one has

$$T_{AB}^{(M)} = \left(p + \rho\right) u_A u_B - p \eta_{AB}.$$  \hspace{1cm} (37)

The energy-momentum tensor of a single scalar field is given by

$$T_{AB}^{(S)} = \Phi_A \Phi_B - \frac{1}{2} \eta_{AB} \Phi_{,MN} \eta^{MN},$$  \hspace{1cm} (38)

where vertical bar denotes components of covariant derivatives relative to the local basis $\theta^A = \epsilon_A^\alpha dx^\alpha$ [see Eqs. (30) and (31)], i.e., $\Phi_A = \epsilon_A^\mu \nabla_\mu \Phi$. Following Ref. [81] it is straightforward to show that a scalar field of the form $\Phi(z) = \epsilon \varepsilon + \varepsilon$, with $\varepsilon, \varepsilon$ const, fulfills the scalar field equation $\Box \Phi = \eta^{MN} \nabla_M \nabla_N \Phi = 0$. Thus, the non-vanishing components of the energy-moment tensor for this scalar field are

$$T_{00}^{(S)} = -T_{11}^{(S)} = -T_{22}^{(S)} = T_{33}^{(S)} = \frac{\varepsilon^2}{2}.$$  \hspace{1cm} (39)

As for the electromagnetic part of energy momentum tensor (56), following Ref. [81], the electromagnetic field tensor $F_{AB}$ given by

$$F_{03} = -F_{30} = E_0 \sin[2\omega(z - z_0)],$$  \hspace{1cm} (40)

$$F_{12} = -F_{21} = E_0 \cos[2\omega(z - z_0)],$$  \hspace{1cm} (41)

satisfies the source-free Maxwell equations which, in the tetrad frame (30), take the form

$$F_{AB}^{\alpha} + \gamma_{\alpha}^{\beta} M_{MB} F_{\beta} + \gamma_{\alpha}^{\beta} F_{\beta}^{\gamma} M_{\gamma} = 0,$$  \hspace{1cm} (42)

$$F_{[AB]} + 2F_{[M} \gamma_{\alpha]}^{\beta} M_{\beta]} = 0,$$  \hspace{1cm} (43)

where the brackets denote total anti-symmetrization and the Ricci rotation coefficients are defined by $\gamma_{\alpha}^{\beta} = -\nabla_\beta \theta^\alpha_A \theta^A_B \theta^B_C$. The non-vanishing components of the
characterized by the two essential parameters \( m \) and \( \omega \), for the cosmological constant \( \Lambda \). The trace equation (29) gives rise to the following constraint:

\[
3\omega^2 - m^2 = k^2 \left( \rho + \frac{e^2}{2} + \frac{\tilde{E}_\alpha^2}{2} \right) + \Lambda, \tag{45}
\]

\[
\omega^2 = k^2 \left( p - \frac{e^2}{2} - \frac{\tilde{E}_\alpha^2}{2} \right) - \Lambda, \tag{46}
\]

\[
m^2 - \omega^2 = k^2 \left( p + \frac{e^2}{2} - \frac{\tilde{E}_\alpha^2}{2} \right) - \Lambda. \tag{47}
\]

To determine the essential parameters \( \omega^2 \) and \( m^2 \), we first substitute (47) into (45) to obtain

\[
2\omega^2 = k^2 (\rho + p + e^2). \tag{48}
\]

Second, we use (46), (47), and (48) to find

\[
m^2 = k^2 (p + p + 2e^2 - \tilde{E}_\alpha^2). \tag{49}
\]

The trace equation (29) gives rise to the following constrain for the cosmological constant

\[
2\Lambda = k^2 (p - p - 2e^2 + \tilde{E}_\alpha^2) \tag{50}
\]

Since ST-homogeneous Gödel-type geometries are characterized by the two essential parameters \( m^2 \) and \( \omega^2 \), the above equations (48) and (49) make explicit how the \( f(\mathcal{R}) \) gravity specifies a pair of parameters \( (m^2, \omega^2) \), and therefore determines a general ST-homogeneous Gödel-type solution, for the combined-fields matter source (36). The general solution given by equations (48) and (49) contains all general relativity Gödel-type known solutions (51) as particular cases. Indeed, the perfect fluid Gödel solution is recovered when \( \epsilon = E_\alpha = 0 \) with \( \rho, p \neq 0 \), whereas the scalar field causal solution (51) is retrieved for \( \rho = p = E_\alpha = 0 \) with \( \epsilon \neq 0 \).

Finally, from equation (49) one has that the combination of scalar plus electromagnetic field with a perfect fluid gives rise to ST-homogeneous Gödel-type solutions in hyperbolic class \( (m^2 > 0) \) when \( E_\alpha^2 < \rho + p + 2e^2 \), in the linear family \( (m^2 = 0) \) for \( E_\alpha^2 = \rho + p + 2e^2 \), and also in the trigonometric class \( (m^2 < 0) \) when \( E_\alpha^2 > \rho + p + 2e^2 \). Moreover, from equation (49) we also have that these three families of ST-homogeneous Gödel-type solutions can also be generated with a simple combination of scalar and electromagnetic fields (thus for \( \rho = p = 0 \)), depending on the relative values of the amplitudes \( e^2 \) and \( E_\alpha^2 \), which give the sign of the term \( 2e^2 - E_\alpha^2 \) in equation (59).

### 5 Concluding remarks

Despite the great success of the general relativity theory, a good deal of effort has recently gone into the study of the so-called modified gravity theories. In the cosmological modeling framework, this is motivated by the fact that these theories provide an alternative way to explain the current accelerating expansion of the Universe with no need to invoke the dark energy matter component. The hybrid metric-Palatini \( f(\mathcal{R}) \) gravity is a recently devised approach to such modified theories, in which it is added to the ordinary Ricci scalar \( R \), in the Einstein-Hilbert Lagrangian, a function, \( f(\mathcal{R}) \), of Palatini curvature scalar \( \mathcal{R} \), which is constructed from the independent connection \( \Gamma^\rho_{\mu\nu} \).

In general relativity, the bare existence of the Gödel solution to Einstein’s equations, for a physically well-motivated perfect-fluid source, makes it apparent that this theory permits solutions with violation of causality on non-local scale, regardless of its local Lorentzian character that ensures the local validation of the causality principle. In the context of the hybrid metric-Palatini \( f(\mathcal{R}) \) gravity theories the space-time manifolds are also assumed to be locally Lorentzian. Hence the chronology and causality structure of special relativity are inherited locally. The nonlocal question, however, is left open, and violation of causality can in principle arise.

Since homogeneous Gödel-type geometries necessarily lead to the existence of closed timelike circles (Section 3.2), which is an unequivocal manifestation of violation of causality, a natural way to tackle this question is by investigating whether the hybrid metric-Palatini \( f(\mathcal{R}) \) gravity theories permit Gödel-type solutions to their field equations. Furthermore, if gravity is to be governed by a \( f(\mathcal{R}) \) there are a number of issues ought to be reexamined in its context, including the question as to whether these theories admit Gödel-type solutions, or would remedy the violation of causality problem by ruling out this type of solutions, which are permitted in general relativity.

In this article, to proceed further with the investigations on the potentialities, difficulties and limitations of \( f(\mathcal{R}) \), we have examined whether \( f(\mathcal{R}) \) gravity theories admit homogeneous Gödel-type solutions for physically well-motivated matter sources. To this end, we have first examined the problem of finding out ST-homogeneous solutions in these hybrid gravity theories whose trace \( T \) (invariant) of the energy-momentum tensor is constant. We have shown that under
this assumption the problem of finding out solutions in the hybrid metric-Palatini $f(R)$ gravity reduces to the problem of determining ST-homogeneous solutions of Einstein’s field equations with a cosmological constant. Employing this far-reaching simplifying result, we first have found a general Gödel-type solution for a source that is a combination of scalar and electromagnetic fields with a perfect fluid. In this general Gödel-type solution solution the essential parameter $m^2$ can be $m^2 > 0$ (hyperbolic family), $m = 0$ (linear class) or $m^2 < 0$ (trigonometric family) depending on the values of the amplitudes $ε$ (scalar field) and $E_0$ (electromagnetic field), and the density $ρ$ and pressure $p$ of the perfect fluid. This general homogeneous Gödel-type solution also contains previously known solutions of the literature as special cases. There emerges from one of the particular solution of the hyperbolic family that every perfect-fluid Gödel-type solution of any $f(R)$ gravity with density $ρ$ and pressure $p$ and satisfying the weak energy conditions $ρ > 0$ and $ρ + p ≥ 0$ is necessarily isometric to the Gödel geometry. This extends to the context of $f(r)$ gravity a theorem established in the context of the general relativity, which states that Gödel solution is the sole perfect fluid solution of Einstein’s equations [83].

Whether or not the physical laws permit the existence of stable time machines in the form of closed timelike curves is a research field in general relativity and other gravity theories. Violation of causality on the other hand raises intriguing logical paradoxes, and is generally seen as undesirable feature in physics. The two most known remedies to these paradoxes are Novikov’s self-consistency principle [86,87,88], which was designed to reconcile the logical inconsistencies by demanding that the only admissible local solutions are those which are globally self-consistent and Hawking’s chronology protection conjecture [89], which suggests that even though closed timelike curves are classically possible to be produced, quantum effects are likely to prevent such time travel. In this way, the laws of quantum physics would prevent closed timelike curves from appearing. In this regard, Hawking and Penrose have also pointed out that severe causality assumptions could risk ‘ruining something that gravity is trying to tell us’ [92], thus, discouraging further investigations. The possible existence of closed timelike curves is also particularly interesting in the quantum realm, where, for example, the quantum systems traversing these curves have been studied [93] and experimental simulation of closed timelike curves have been undertaken [94].

To conclude, we emphasize that the bare existence of the ST-homogeneous Gödel-type solutions that we have found makes apparent that the hybrid metric-Palatini $f(R)$ gravity does not remedy at a classical level the causal pathology in the form of closed timelike curves that arises in the context of general relativity. We are not aware of a quantum gravity theory following the hybrid metric-Palatini structure, though.
