Recommending Oral Probiotics to Reduce Winter Antibiotic Prescriptions in People With Asthma: A Pragmatic Randomized Controlled Trial

**ABSTRACT**

**PURPOSE** Evidence from studies mainly in children has shown that orally administered probiotics may prevent respiratory tract infections and associated antibiotic use. We evaluated whether advice to take daily probiotics can reduce antibiotic prescribing for winter respiratory tract infections in people with asthma.

**METHODS** We conducted a randomized controlled, parallel-group pragmatic study for participants aged 5 years and older with asthma in a UK primary care setting. The intervention was a postal leaflet with advice to take daily probiotics from October 2013 to March 2014, compared with a standard winter advice leaflet. Primary outcome was the proportion of participants prescribed antibiotics for respiratory tract infections.

**RESULTS** There were 1,302 participants randomly assigned to a control group (n = 650) or intervention group (n = 652). There was no significant difference in the primary outcome measure, with 27.7% receiving antibiotics in the intervention group and 26.9% receiving antibiotics in the control group (odds ratio = 1.04; 95% CI, 0.82-1.34). Uptake of probiotics was low, but outcomes were similar in those who accessed probiotics (adjusted odds ratio = 1.08; 95% CI, 0.69-1.69, compared with controls). We also found no evidence of an effect on respiratory tract infections or asthma exacerbations.

**CONCLUSIONS** In this pragmatic community-based trial in people with asthma, we found no evidence that advising use of winter probiotics reduces antibiotic prescribing.

Ann Fam Med 2016;14:422-430. doi: 10.1370/afm.1970.

**INTRODUCTION**

Acute respiratory tract infection is the most common reason for attending primary care appointments and accounts for 80% of antibiotic prescriptions.1 A Cochrane review in 2011 found that, in randomized controlled trials (RCTs) of specific patient populations, probiotic prophylaxis significantly reduces both upper respiratory tract infections (URTIs) and antibiotic prescribing rates for these infections.2 We wanted to determine whether giving advice to take regular probiotics is an effective strategy for reducing antibiotic prescribing rates for respiratory tract infections in people with asthma, most of whom are older than the predominantly young child populations analyzed in the Cochrane review. People with asthma are especially vulnerable to viral URTIs, which are the most common trigger of acute asthma exacerbations3 and contribute substantially to the burden of unnecessary antibiotic prescriptions. Only 1 previous pilot study assessed effects of probiotics (combined with acupuncture) on respiratory tract infection rates in people with asthma. In this trial, reduced infection rates were found with the intervention, but the study was underpowered (n = 17), and the findings were not statistically significant (P = .18).4 Probiotics alone for preventing antibiotic use in asthmatics have not, to our knowledge, been evaluated in a prospective controlled trial.4-7
We undertook a pragmatic trial to assess whether advice to take probiotic treatment, implemented as part of routine winter infection advice, could reduce antibiotic prescription rates and respiratory tract infections in older children and adults with asthma in a primary care setting.

METHODS

Study Design
This study was a parallel-group prospective RCT of a pragmatic community-based intervention—advice leaflets including recommendations to take a probiotic supplement daily through the winter months—for reducing antibiotic prescription in participants with asthma.

PARTICIPANTS
All participants were registered patients at Ashfields Primary Care Centre, a semiurban practice in the United Kingdom caring for 23,000 patients with a nationally representative socioeconomic and racial mix. Inclusion criteria were age 5 years or older (because a diagnosis of asthma in preschool children is unreliable), a current diagnosis of asthma, and a random selection of 1 person per household only. All patients in the practice population registered with a current diagnosis of asthma and fulfilling the inclusion criteria were enrolled in the study.

Ethics and Consent
The study was approved by London-Bloomsbury Research Ethics Committee (reference 13/LO/0783). Informed consent was not obtained from study participants, although they were given the option to request that their data were not included in study analyses.

Randomization, Treatment Allocation, and Blinding
Where there was more than 1 eligible participant per household, the participant was selected randomly. For included participants, the randomization sequence was computer generated with a 1-to-1 intervention-to-control ratio in random block sizes of 4, 6, and 8, stratified by age (ages 5 to 18, 19 to 34, 35 to 59, and ≥60 years). Clinical staff and the outcome assessor were blinded to treatment allocation until all study data had been entered, cleaned, and locked in the study database to be sent to the study statistician.

Study Intervention
In the United Kingdom, all patients with asthma are invited to receive annual influenza vaccination. In this study, participants were sent information leaflets (Supplemental Appendix 1, http://www.annfammed.org/content/14/5/422/suppl/DC1) during a 2-week period in late September 2013, together with their routine invitation for annual influenza vaccination. Participants randomized to the control group received a leaflet with standard advice about measures that have been reported to help reduce infections or asthma exacerbations. Participants randomized to the intervention group received an information leaflet with an additional section recommending taking 1 Lab4 (Cultech Ltd) probiotic capsule daily from October to the end of March. In addition, the intervention group received 3 tokens with which they could request 2 months of supplies at a time from the manufacturer via telephone or Internet, which are the methods by which Lab4 is currently sold. Lab4 is a patented blend of 4 probiotic bacteria comprising 2 strains of Lactobacillus acidophilus CUL60 (NCIMB 30157) and CUL21 (NCIMB 30156), Bifidobacterium bifidum CUL20 (NCIMB 30153) and B. animalis (var lactis) CUL34 (NCIMB 30172) at a total $2.5 \times 10^{10}$ colony-forming units per capsule.

Outcome Measures
All outcome measures were prespecified in the statistical analysis plan, which was finalized before database lock. The primary outcome measure was the proportion of participants who, within the 6-month period for which probiotics were recommended, were prescribed at least 1 new course of 1 of the following antibiotics locally used for respiratory tract infections: amoxicillin, azithromycin, cefaclor, cephalaxin, ciprofloxacin, clarithromycin, co-amoxiclav, doxycycline, erythromycin, or phenoxybenzamethicillin. Secondary outcomes were based on consultations for LRTIs, lower respiratory tract infections (LRTIs), asthma exacerbation or any respiratory tract infection, and the number and cost of antibiotic courses prescribed during the 6-month intervention period. Full outcome measures, along with methods used to define different forms of respiratory tract infection, asthma exacerbations, and new episodes of illness, are described in Supplemental Appendix 2, http://www.annfammed.org/content/14/5/422/suppl/DC1.

Outcome data were extracted from participants' medical records for the 6-month period when probiotic consumption was recommended, October 1, 2013, to March 31, 2014, by a single investigator blinded to treatment allocation.

Statistical Analysis
In the study primary care practice, 28.4% of all patients with a current asthma diagnosis had received 1 or more of the specified antibiotics during the winter before this study (October 2012 to March 2013). The Cochrane systematic review found probiotics are associated with reduced antibiotic prescribing for acute...
ORAL PROBIOTICS

URTI compared with placebo (relative risk [RR] = 0.67; 95% CI, 0.45-0.98). For an 80% power to detect a smaller effect size (RR = 0.77) in this pragmatic study, with anticipated 20% loss of outcome data and a 5% contamination rate in the control group, we planned to randomize 1,258 participants.

Intention-to-treat analysis included all participants with data available for the relevant outcome in the groups to which they were originally assigned, regardless of whether they took the intervention. Per protocol analyses were used to compare 2 subgroups—participants who ordered probiotics 1 or more or 2 or more times—with the control group. Adjusted analyses used logistic regression for binary outcomes, linear regression for continuous outcome variables, and t tests for cost data with boot-strapping to provide robust confidence intervals on these estimates. Variables adjusted for were age-group, sex, asthma severity (see Supplemental Appendix 3, http://www.annfammed.org/content/14/5/422/suppl/DC1), and numbers of courses of any antibiotics prescribed in the 12 months before entry into the trial. Sensitivity analyses further adjusted for receiving influenza vaccine during the trial. Multiple comparisons were assessed using the Hochberg procedure to control for false discovery.16

RESULTS

Recruitment and flow of participants are displayed in Figure 1. Losses to follow-up were low—14 (2.1%) participants in the intervention group, 18 (2.8%) in the control group. Primary analyses included the remaining 1,270 participants (638 intervention; 632 control), with the 2 fatalities also included in adverse events analysis. The recommended probiotic was accessed by 121 (19.0%) participants in the intervention group at least once (2 or more months’ supply), and 86 (13.5%) at least twice (4 or more months’ supply). Blinding and contamination are discussed in Supplemental Appendix 4, http://www.annfammed.org/content/14/5/422/suppl/DC1.

Outcome of Randomization

Table 1 shows the baseline characteristics of both randomization groups with few significant differences between randomized groups. The participants who accessed probiotics in the intervention group—used for per protocol analyses—show some differences from the control group. They were generally older and had asthma diagnosed later in life, and they were more likely to have had an asthma review and influenza vaccine in the last 12 months. There was no significant difference between groups in the proportion of prescribed antibiotics in the last 12 months or in other chronic disease rates, when adjusted for age and sex.

Effect of the Study Intervention on Antibiotic Use

Table 2 shows the study outcomes relating to antibiotic use for the intention-to-treat and per protocol analyses. We found no difference between treatment groups in our primary outcome measure—prescription of a specified probiotic during the study period—in intention-to-treat (odds ratio [OR] = 1.04; 95% CI, 0.82-1.34) or per protocol analyses for 1 or more probiotic token used (adjusted odds ratio [AOR] 1.08; 95% CI, 0.69-1.69) or 2 or more probiotic tokens used (AOR 1.04; 95% CI, 0.62-1.75; Figure 2). We also
found no difference in secondary outcomes—use of any antibiotic, any antibiotic given for URTI or any respiratory tract illness, number of antibiotic courses, or total cost of antibiotics—in unadjusted or adjusted analyses. We found weak evidence for a higher mean number of respiratory tract episodes for which antibiotics were given in the intervention (intention-to-treat) group compared with the control group (ie, a detrimental effect), but when adjusted for multiple testing this was not found to be significant. For the 10 separate antibiotic outcomes evaluated, the threshold is \( P = .005 \), using the false discovery method of Hochberg.

### Table 1. Baseline Characteristics of Study Participants

| Characteristic                  | Randomized Control Group (n = 650) | Randomized Intervention Group (n = 652) | Obtaining any Probiotic Package (n = 123) | Obtaining 2-3 Probiotic Packages (n = 88) |
|--------------------------------|-----------------------------------|----------------------------------------|----------------------------------------|----------------------------------------|
| Age-group, y                    |                                   |                                        |                                        |                                        |
| 5-18, No. (%)                   | 80 (12)                           | 80 (12)                                | 10 (8)                                 | 7 (8)                                  |

COPD = chronic obstructive pulmonary disease; TIA = transient ischemic attack.

Note: Comparisons are made between randomized groups and for those within the intervention group who obtained probiotic packages at least once, and 2 to 3 times.

\( a \) Range of 25th to 75th percentile.

\( b \) \( P < .001 \).

\( c \) \( P < .05 \)

\( d \) \( P < .01 \) comparing intervention group or per protocol groups obtaining probiotics with the control group (unadjusted analysis). No other such comparisons were significant.
Effect of the Study Intervention on Respiratory Tract Health

Table 3 shows outcomes related to respiratory tract health for the intention-to-treat and per protocol analyses. We found no difference between treatment groups in respiratory tract outcomes: any URTI, any asthma exacerbation, any respiratory tract infection, or total episodes of each of these categories in intention-to-treat or per protocol analyses, using unadjusted or adjusted analyses. We found weak evidence for detrimental effects in the intervention group in the number of people with an LRTI and mean number of LRTIs per person, but these were not significant when adjusted for multiple testing (threshold for respiratory tract outcomes $P = .0125$).

Adverse Effects of the Intervention

There was no significant difference in serious adverse events between
treatment groups (Table 4) when corrected for multiple testing. This finding is further discussed in Supplemental Appendix 5, http://www.annfammed.org/content/14/5/422/suppl/DC1.

**DISCUSSION**

In this pragmatic RCT of a recommendation for adults and older children with asthma to take daily probiotics during a single winter, we found no evidence that the intervention of advice leaflets recommending probiotic supplementation, with free access to such supplements, can reduce antibiotic prescriptions or promote improved respiratory tract health. Although only approximately 20% of these participants followed the intervention leaflet advice and took probiotics (per protocol groups), we found no evidence that probiotics influenced study outcomes in the per protocol groups. It is possible that those who accessed the probiotic would have had more respiratory tract infections and resulting antibiotics without the probiotic, but adjustment for likely confounding factors failed to show any evidence to support this likelihood (see also Supplemental Appendix 6, http://www.annfammed.org/content/14/5/422/suppl/DC1). These results differ from previous findings in controlled trials mainly involving younger children that probiotics reduce respiratory tract infections and resulting antibiotic prescription rates, and they cast doubt on the reproducibility of those findings in older children and adults with asthma using information leaflets. Our data suggest that real-world use of probiotics to prevent winter infections and reduce antibiotic use cannot yet be recommended despite positive findings in a Cochrane review—at least not in older children and adults with asthma. Winter infections are not necessarily all captured, as we only analyze those reported to the physician. There is little reason to believe, however, that there would be differential reporting of infections between treatment arms. Antibiotic prescriptions are generally captured data, because they would appear in general practice records, so this more important outcome is collected robustly.

The 2011 Cochrane systematic review found participants treated with probiotics had a reduced risk of antibiotic use for acute URTIs (RR = 0.67; 95% CI, 0.45-0.98) and for 1 or more URTIs (OR = 0.55; 95% CI, 0.35-0.86). Our data challenge this finding—our 95% confidence intervals do not overlap with the point estimate of the odds ratios or relative risks of the Cochrane review. Differences between our study and those in the Cochrane review include the age-group studied, our focus on people with asthma, the probiotic strain(s) used, and our pragmatic trial design—the use of information leaflets and the offer of free probiotics.

The developing immune system at younger ages may be more sensitive to immunological changes in the gastrointestinal tract triggered by taking probiotics, and 95% of subjects included in the Cochrane review were aged under 8 years compared with only 3% in our study. Three recent RCTs published subsequent to the Cochrane review found positive effects of probiotics in pediatric populations when used to prevent respiratory tract infections. The studies in the Cochrane review also included very few people with asthma, and it is possible that the immunopathology of asthma leads to a differential response to probiotics. One small pilot study suggested probiotics may have positive effects in asthma, although the inconclusive findings were due to low statistical power.

All 3 studies included in the meta-analysis on antibiotic prescribing in the Cochrane review, and all 4 studies in another meta-analysis showing similar
