Abstract

Our first result concerns a characterisation by means of a functional equation of Poisson point processes conditioned by the value of their first moment. It leads to a generalised version of Mecke’s formula. En passant, it also allows to gain quantitative results about stochastic domination for Poisson point processes under linear constraints.

Since bridges of a pure jump Lévy process in Rd with a height a can be interpreted as a Poisson point process on space-time conditioned by pinning its first moment to a, our approach allows us to characterize bridges of Lévy processes by means of a functional equation. The latter result has two direct applications: first we obtain a constructive and simple way to sample Lévy bridge dynamics; second it allows to estimate the number of jumps for such bridges. We finally show that our method remains valid for linearly perturbed Lévy processes like periodic Ornstein-Uhlenbeck processes driven by Lévy noise.

Keywords. Conditioned point processes, Mecke’s formula, Lévy bridges, periodic Ornstein-Uhlenbeck.

1 Introduction and notations

In this paper we first consider Poisson point processes conditioned to satisfy linear constraints. As we will see later, they arise quite naturally in various situations, when studying bridges of Lévy processes or periodic Ornstein-Uhlenbeck processes. What makes their study mathematically interesting (and intricate) is the fact that, in contrast with the Gaussian case where linear conditionings preserve Gaussianity, linear conditionings of Poisson point processes are no longer Poissonian. We propose a characterization of these conditional laws in Theorem

∗giovanni.conforti@polytechnique.edu
†kosenkova@math.uni-potsdam.de
‡roelly@math.uni-potsdam.de
2.6 through the functional equation (*) which can be seen as a generalized version of the celebrated iterated Mecke identity. Recall that Mecke’s formula quantifies how much adding or removing a point from a random point configuration affects its probability. In our formula, indeed, we balance the cancellation and addition of points in such a way that the constraint is preserved. Let us precise our approach. Consider a Poisson point process \( P(d\mu) \) on \( \mathbb{R} \) under the linear constraint that the first moment \( \mathcal{M}_1(\mu) := \int_{\mathbb{R}} x \mu(dx) \) of any point configuration \( \mu \) is fixed to be equal to \( a \). To analyse the conditioned probability \( P(d\mu | \mathcal{M}_1 = a) \) we introduce an integro-difference operator on point measures \( \mu \), which cancels a randomly chosen point \( x \) of the support of \( \mu \) and create two new points at places \( x' \) and \( x'' \) whose sum \( x' + x'' \) equals that of the removed one, \( x \). Therefore the first moment of the transformed point measure remains unchanged, equal to \( \mathcal{M}_1(\mu) \).

Identity (*) will also be used to dominate stochastically with a Poisson random variable the law of the total mass of a Poisson point process conditioned by its first moment. This result is of particular interest since these conditioned laws cannot be computed in explicit form. Our result furnishes upper- or lower-bounds.

The main purpose of our study is presented in Section 3. Considering a pure jump process as a point measure on a space-time set, we transpose our previous results in order to obtain a characterization of bridges of pure jump Lévy processes as the unique solutions of a functional equation. Indeed the former constraint on the first moment \( \mathcal{M}_1 \) corresponds in this context to fix the global size of the jumps of a path, or equivalently the height of the bridge.

Notice that in Equation (3.5) which characterizes the set of pure jump processes having the same bridges than a given pure jump Lévy processes \( \mathbb{P}_\nu \), a parameter \( \chi_\nu \) appears, called reciprocal characteristic. This bivariate function is computed from the diffuse jump measure \( \nu \) of \( \mathbb{P}_\nu \) and encodes all the necessary information to construct the bridges. In this respect, our result extends to the case of diffuse jumps or random walks on graphs, see [1, 3, 2]. Furthermore, following a first quantization strategy outlined in [7, 6], our characterization can be used to construct a dynamics whose invariant law is a Lévy bridge, see Subsection 3.2.

The paper is organized as follows. In Section 2 we exhibit in Theorem 2.6 a characterization formula for Poisson point processes conditioned by their first moment. In particular, we deduce from that explicit stochastic comparisons results. In Section 3 we apply our former characterization to bridges of pure jump Lévy processes, whereas in Section 4 we apply them to the study of periodic Ornstein-Uhlenbeck processes driven by a Lévy process.

Let us now introduce some useful notations which will appear in the paper.

- On a measured state space \( \Gamma \) we consider \( \mathcal{M}(\Gamma) \) (resp. \( \mathcal{M}_f(\Gamma) \)), the set of point measures (resp. finite point measures) over \( \Gamma \).
  If a point \( \gamma \in \Gamma \) belongs to the set of atoms of \( \mu \in \mathcal{M}(\Gamma) \) we simply write \( \gamma \in \mu \).
  Therefore, if \( \mu \) is not reduced to the zero measure, denoted by \( 0 \), \( \mu = \sum_{\gamma \in \mu} \delta_\gamma \).
- \( \mathcal{P}(X) \) is the set of probability measures on a space \( X \). In particular

\[ \text{poi}_\lambda \in \mathcal{P}(\mathbb{N}) \]
is the law of a Poisson random variable with mean \( \lambda > 0 \) and

\[
P_{\lambda} \in \mathcal{P}(\mathcal{M}(\Gamma))
\]
denotes the Poisson point process on \( \Gamma \) of intensity \( \rho(d\gamma) \), where \( \rho \) is a positive finite measure on \( \Gamma \).

- For any point measure \( \mu \in \mathcal{M}(\Gamma) \), its \( n \)-th factorial product, \( n \in \mathbb{N}^* \), is defined as the point measure on the product space \( \Gamma^{\otimes n} \) given by

\[
\mu_{(n)}(d\gamma_1, \cdots, d\gamma_n) := \mu(d\gamma_1)(\mu - \delta_{\gamma_1})(d\gamma_2) \cdots (\mu - \cdots - \delta_{\gamma_{n-1}})(d\gamma_n) \tag{1.1}
\]

In other words (see e.g. [4, p. 70])

\[
(\gamma_1, \cdots, \gamma_n) \in \mu_{(n)} \iff \forall i, \gamma_i \in \mu \text{ and } \not\exists i, j \text{ such that } \gamma_i = \gamma_j.
\]

In particular, since the point measure \( \mu_{(2)} \) on \( \Gamma^{\otimes 2} \) satisfies

\[
\mu_{(2)} := \sum_{\gamma, \gamma' \in \mu} \delta_{(\gamma, \gamma')} - \sum_{\gamma \in \mu} \delta_{(\gamma, \gamma)}, \tag{1.2}
\]

its support is the product of the support of \( \mu \) with itself minus the diagonal.

### 2 Splitting and conditioning a Poisson point process

#### 2.1 Mecke bivariate formula as tool to characterize a Poisson point process

Let us shortly recall in this subsection how useful (reduced) Campbell measures are to characterize a Poisson point process.

First define on the product space \( \Gamma \times \mathcal{M}(\Gamma) \) the map \( \varsigma_+ \) which adds an atom to a point measure:

\[
\forall (\gamma, \mu) \in \Gamma \times \mathcal{M}(\Gamma), \quad \varsigma_+(\gamma, \mu) := (\gamma, \mu + \delta_{\gamma}) \tag{2.1}
\]

Its inverse map \( \varsigma_- \) is only defined on the set \( \{ (\gamma, \mu) : \gamma \in \mu \} \subset \Gamma \times \mathcal{M}(\Gamma) \). It cancels one atom of a point measure:

\[
\varsigma_-(\gamma, \mu) := (\gamma, \mu - \delta_{\gamma}). \tag{2.2}
\]

Let us also introduce the bivariate version of \( \varsigma_+ \) corresponding to the addition of two atoms to a point measure:

\[
\forall (\gamma, \gamma', \mu) \in \Gamma^2 \times \mathcal{M}(\Gamma), \quad \varsigma_+^{(2)}(\gamma, \gamma', \mu) := (\gamma, \gamma', \mu + \delta_{\gamma} + \delta_{\gamma'}). \tag{2.3}
\]

On the other side, the cancellation of two atoms of a point measure \( \mu \) is defined and denoted as follows:

\[
\text{for } \gamma, \gamma' \in \mu, \gamma \neq \gamma', \quad \varsigma_-^{(2)}(\gamma, \gamma', \mu) := (\gamma, \gamma', \mu - \delta_{\gamma} - \delta_{\gamma'}). \tag{2.4}
\]

**Definition 2.1** (First order Campbell measures). For any point process \( Q \) on \( \Gamma \), its one-to-one associated Campbell measure \( C_Q \) (resp. reduced Campbell measure \( C_Q^0 \)) is defined as the following measure on \( \Gamma \times \mathcal{M}(\Gamma) \):

\[
C_Q(d\gamma, d\mu) := \mu(d\gamma)Q(d\mu) \quad \text{resp.} \quad C_Q^0(d\gamma, d\mu) := C_Q \circ (\varsigma_-)^{-1}(d\gamma, d\mu).
\]
The celebrated Slivnjak-Mecke characterization offers an elegant identification of Poisson point processes via their Campbell measure. For any $\rho$, positive finite measure on $\Gamma$,  

$$Q = P_\rho \iff C_Q^1 = \rho \otimes Q \iff C_Q = \left(\rho \otimes Q\right) \circ (\varsigma_+)^{-1}. \quad (2.5)$$

**Remark 2.2.** For any $\gamma \in \Gamma$, denote by $\Delta_\gamma = \delta_\gamma$ the degenerated (deterministic) point process concentrated on $\delta_\gamma \in \mathcal{M}(\Gamma)$. The latter identities (2.5) can be rewritten as  

$$C_Q = \left(\rho(d\gamma)\Delta_\gamma(d\mu)\right) \star Q$$

where $\star$ denotes the following generalized convolution between a measure $C$ on $\Gamma \times \mathcal{M}(\Gamma)$ and a point process $Q$ on $\Gamma$: for any measurable positive test functions $F(\gamma, \mu)$ on $\Gamma \times \mathcal{M}(\Gamma)$,  

$$\int \! F(\gamma, \mu) C \star Q(d\gamma, d\mu) := \int \int \! F(\gamma, \mu + \nu) C(d\gamma, d\nu)Q(d\mu).$$

A generalisation of this equation in $Q$, where the measure $\rho(d\gamma)\Delta_\gamma(d\mu)$ is replaced by a more complicated one, is the subject of a recent study, see e.g. [1 2].

Iterating the above procedure, one can define Campbell measures with second (and higher) order, see e.g. [4, Eq. (15.6.14)].

**Definition 2.3 (Second-order Campbell measures).** For any point process $Q$ on $\Gamma$, one defines the second-order factorial Campbell measure $C_Q^{(2)}$ on $\Gamma^2 \times \mathcal{M}(\Gamma)$ (resp. second-order reduced factorial Campbell measure $C_Q^{(2),!}$) as the following measure:

$$C_Q^{(2)}(d\gamma, d\gamma', d\mu) := \mu^{[2]}(d\gamma, d\gamma')Q(d\mu)$$

resp.  

$$C_Q^{(2),!}(d\gamma, d\gamma', d\mu) := C_Q^{(2)} \circ (\varsigma_+^{-1})(d\gamma, d\gamma', d\mu).$$

Identities (2.5) then lead to the following Mecke’s bivariate formula satisfied by the Poisson point process $P_\rho$ (see e.g. [4, p. 524]) or [9, Section 4.2]:  

$$C_{P_\rho}^{(2)}(d\gamma, d\gamma', d\mu) = \rho \otimes \rho \otimes P_\rho (d\gamma, d\gamma', d\mu)$$

$$C_{P_\rho}^{(2),!}(d\gamma, d\gamma', d\mu) = \left(\rho \otimes \rho \otimes P_\rho\right) \circ (\varsigma_+^{-1})(d\gamma, d\gamma', d\mu). \quad (2.6)$$

**2.2 A formula satisfied by the split Poisson point process**

From now on we need a group structure on the state space in order to define an addition and its inverse operation. For simplicity, we take for the rest of the paper $\Gamma = \mathbb{R}^d$. We also suppose that the measure $\rho$ on $\gamma$ admits a density function with respect to Lebesgue measure denoted by $\rho$ too.

We then consider a splitting transformation on point measures on $\Gamma$ consisting in splitting one of their atoms into two new ones, in a specific way. More precisely, define on the set $\{(\gamma, \gamma', \mu) : \gamma \in \mu \} \subset \Gamma^2 \times \mathcal{M}(\Gamma) \setminus \{0\}$ the splitting map $\mathcal{S}$:

$$(\gamma, \gamma', \mu) \mapsto \mathcal{S}(\gamma, \gamma', \mu) := (\gamma - \gamma', \gamma', \mu - \delta_\gamma + \delta_{\gamma'} + \delta_{\gamma - \gamma'}). \quad (2.7)$$

The first order Campbell measure of a Poisson point process and its second order Campbell measure are linked through the transformation $\mathcal{S}$ in the following way. 
Proposition 2.4. Under the Poisson point process of intensity $\rho$, $\mathbf{P}_\rho$, the following identity holds:

$$\chi^{(2)}_\rho \mathbf{P}_\rho = (C_{\mathbf{P}_\rho} \otimes d\gamma') \circ \mathcal{S}^{-1} \quad (2.8)$$

where the bivariate function $\chi_\rho$ satisfies

$$\chi_\rho(\gamma, \gamma') := \frac{\rho(\gamma + \gamma')}{\rho(\gamma \rho(\gamma'))}. \quad (2.9)$$

Proof. Integrate a positive test function $F$ under the left hand side of (2.8):

$$\int F(\gamma''', \gamma'', \mu) \chi^{(2)}_\rho (\gamma''', \gamma'', \gamma', \gamma') \mathbf{C}^{(2)}_{\mathbf{P}_\rho} (d\gamma'', d\gamma', d\mu)$$

$$= \int F(\gamma - \gamma', \gamma', \mu + \delta_{\gamma'''} + \delta_{\gamma''} + \delta_{\gamma} - \delta_{\gamma'} - \delta_{\gamma} + \delta_{\gamma}) \rho(d\gamma') \rho(d\gamma) \rho(d\mu) d\gamma'$$

$$= \int (F \circ \mathcal{S}) (\gamma, \gamma', \mu) \mathbf{C}_{\mathbf{P}_\rho}(d\gamma, d\mu) d\gamma',$$

which corresponds to the integral of $F$ under the right hand side of (2.8). \qed

Corollary 2.5. Identity (2.8) gains interesting interpretations by choosing the integrands in an appropriate way. Since the intensity $\rho$ is finite, $\mathbf{P}_\rho$ a.s. carries finite random point measures, that is $\mu(\Gamma) < +\infty$ a.s.. Now, take as test function $F$ a function of the following type: $F(\gamma, \gamma', \mu) := \frac{1_{\mu(\Gamma) > 1}}{\mu(\Gamma) - 1} \tilde{F}(\mu) \varphi(\gamma')$, where $\varphi$ is a probability density function. Equality (2.8) rewrites:

$$E_{\mathbf{P}_\rho} (\tilde{F}(\mu) D_{\rho}(\mu)) = E_{\mathbf{P}_\rho} \left( \int_{\mathbb{R}^2} \tilde{F}(\mu - \delta_{\gamma} + \delta_{\gamma'} + \delta_{\gamma''} - \delta_{\gamma'} - \delta_{\gamma} + \delta_{\gamma}) \frac{\mu(d\gamma)}{\mu(\Gamma)} \varphi(\gamma') d\gamma' \right)$$

where

$$D_{\rho}(\mu) := \frac{\int_{\mathbb{R}^2} \chi_\rho(\gamma, \gamma') \varphi(\gamma') \mu(\Gamma)^{[2]}(d\gamma', d\gamma')}{\mu(\Gamma) - 1} 1_{\mu(\Gamma) > 1}. \quad (2.10)$$

This means that if you transform any realisation $\mu$ of the Poisson point process $\mathbf{P}_\rho$ as follows:

1. if $\mu \neq 0$, select randomly one atom $\gamma$ of $\mu$
2. sample $\gamma'$ randomly according to the probability law with density $\varphi$
3. and replace the selected atom $\gamma$ by both atoms $\gamma'$ and $\gamma - \gamma'$;

then the obtained image measure is absolutely continuous with respect to $\mathbf{P}_\rho$ and the explicit density is expressed by (2.10) in terms of the function $\chi_\rho$. 

5
2.3 How to characterize the split Poisson point process pinned by its first moment

Recall the definition of the first moment of a finite point process $\mu \neq \emptyset$ on $\Gamma$:

$$\mathfrak{M}_1(\mu) := \int_{\Gamma} \gamma \, \mu(d\gamma) = \sum_{\gamma \in \mu} \gamma.$$ 

Clearly one has $\mathfrak{M}_1(\emptyset) = 0$.

Remark that the first moment of a point measure, which is a random variable with values in $\Gamma$, remains invariant under the splitting transform $\mathcal{S}$ introduced above:

$$\mathfrak{M}_1(\mu - \delta_\gamma + \delta_{\gamma'} + \delta_{\gamma''}) = \mathfrak{M}_1(\mu), \quad \forall (\mu, \gamma, \gamma') \in \mathcal{M}_f(\Gamma) \times \Gamma^2. \quad (2.11)$$

The goal of this section is first, revisiting (2.8), to show that this identity remains true if one conditions the probability $P_\rho$ by the event $\mathfrak{M}_1^{-1}(a) = \{ \mu : \mathfrak{M}_1(\mu) = a \}$, $a \in \Gamma$; much more, we will prove that (2.8) indeed characterizes the conditioned probability $P_\rho^a(\mu) := P_\rho(\mu | \mathfrak{M}_1 = a)$, $a \neq 0$, within the set of probability measures on $\mathcal{M}_f(\Gamma)$ with support included in $\mathfrak{M}_1^{-1}(a)$.

Notice that, since $\rho$ is diffuse, the law of $\mathfrak{M}_1$ under $P_\rho(\cdot | \{\emptyset\})$ is diffuse and therefore, for any $a \neq 0$, the event $\{ \mathfrak{M}_1 = a \}$ is $P_\rho$-negligible. Nevertheless the conditioned probability $P_\rho^a(\mu | \mathfrak{M}_1 = a)$ can be constructed as limit measure for $\varepsilon \to 0$ of the conditioned measures $P_\rho^{a,c}(\cdot) := P_\rho(\cdot | \mathfrak{M}_1 \in B(a, \varepsilon))$ where $B(a, \varepsilon)$ denotes the ball centered in $a$ with radius $\varepsilon$.

**Theorem 2.6.** Suppose $Q$ is a finite point process on $\Gamma$ and $a \in \Gamma \setminus \{0\}$. Then

$$\left\{ \begin{array}{l}
\chi_\rho \ C_Q^{(2)}(\cdot) \subseteq (C_Q \otimes d\gamma') \circ \mathcal{S}^{-1} \\
Q(\mathcal{M}_f(\Gamma) \cap \mathfrak{M}_1^{-1}(a)) = 1
\end{array} \right. \quad \iff \quad Q = P_\rho^a.
$$

In other words, $P_\rho^a$ is the only finite point process on $\Gamma$ concentrated on the set $\{ \mathfrak{M}_1 = a \}$ which fulfills the identity (*).

**Proof.** To prove that $P_\rho^a$ fulfills Identity (*) is straightforward. Disintegrate the measure $P_\rho$ along all possible values of $\mathfrak{M}_1$: $P_\rho = \int P_\rho^a \, \lambda_\rho(da)$ where $\lambda_\rho$ is the image measure of $P_\rho$ under $\mathfrak{M}_1$, and write the identity (2.8) tested on functions defined on $\Gamma^2 \times \mathcal{M}_f(\Gamma)$ of the form $f(\mathfrak{M}_1(\mu)) F(\gamma, \gamma', \mu)$. One obtains, using the invariance property (2.11):

$$\int f(\mathfrak{M}_1(\mu)) \, F(\gamma, \gamma', \mu) \, \chi_\rho(\gamma, \gamma') \, \mu^{[2]}(d\gamma, d\gamma') P_\rho^a(d\mu) \lambda_\rho(da)$$

$$= \int f(\mathfrak{M}_1 \circ \mathcal{S}(\mu)) \, F \circ \mathcal{S}(\gamma, \gamma', \mu) \, \mu(d\gamma') P_\rho^a(d\mu) d\gamma' \lambda_\rho(da)$$

$$\iff \int f(a) \left( \int F(\gamma, \gamma', \mu) \, \chi_\rho(\gamma, \gamma') \, \mu^{[2]}(d\gamma, d\gamma') P_\rho^a(d\mu) \right) \lambda_\rho(da)$$

$$= \int f(a) \left( \int F \circ \mathcal{S}(\gamma, \gamma', \mu) \, \mu(d\gamma') P_\rho^a(d\mu) d\gamma' \right) \lambda_\rho(da).$$

This is enough to deduce that (*) holds for $Q = P_\rho^a$.

Before proving the implication from the left to the right in Theorem 2.6, we develop some necessary tools. First we introduce for any finite point process $Q$ its associated diminished point process $Q^-$, which is constructed by removing one atom at random from any realization of $Q$:
Definition 2.7 (Diminished point process). The diminished point process $Q^-$ of a point process $Q \in \mathcal{P}(\mathcal{M}_f(\Gamma))$ which does not carry the zero measure is defined as follows: for any positive test function $F$ on $\mathcal{M}_f(\Gamma)$,

$$E_{Q^-}(F) = E_Q \left( \int_{\Gamma} F(\mu - \delta_{\gamma}) \frac{\mu(d\gamma)}{\mu(\Gamma)} \right).$$ \hspace{1cm} (2.12)

The end of the (tricky) proof of Theorem 2.6 is now a direct consequence of the next three propositions.

For $a \neq 0$ the conditioned point process $P^a$, which does not carry the zero measure and is concentrated on a $P$-negligible set, is singular with respect to $P^a$. Nevertheless, it is remarkable that its diminished version $(P^a^-)$ is absolutely continuous with respect to $P$, as stated in the next proposition.

Proposition 2.8. For any $a \neq 0$ the diminished conditioned Poisson point process $(P^a^-)$ is absolutely continuous with respect to $P$ and its density is proportional to $\frac{\rho(a - \mathfrak{M}(1))}{\mu(\Gamma) + 1}$.

Proposition 2.9. Suppose the finite point process $Q$ fulfills (*) and, for some $a \neq 0$, $Q(\mathfrak{M} = a) = 1$. Then $Q^-$ is absolutely continuous with respect to $P$ and its density is proportional to $\frac{\rho(a - \mathfrak{M}(1))}{\mu(\Gamma) + 1}$.

Proposition 2.10. Suppose the finite point process $Q$ is concentrated on $\{\mathfrak{M} = a\}$. If its diminished version satisfies $Q^- = (P^a^-)$ then $Q = P^a$.

Proof of Proposition 2.8.

Let us first prove that $(P^a^-)$ is absolutely continuous w.r.t. $P$. Take $\varepsilon < |a|$. Thus, for any $\mu$ in the support of $P^a$, $\mathfrak{M}(\mu)$ does not vanish which implies that $P^a$ does not carry the zero measure. Then for all functions $F$ bounded and measurable:

$$E_{(P^a^-)}(F) = \int_{\Gamma} \int_{\Gamma} F(\mu - \delta_{\gamma}) \frac{\mu(d\gamma)}{\mu(\Gamma)} \cdot (P^a)(d\mu)$$

$$= \frac{1}{Z^a} \int_{\Gamma} \int_{\Gamma} 1_{B(a,\varepsilon)} \circ \mathfrak{M}(\mu) F(\mu - \delta_{\gamma}) \frac{1}{\mu(\Gamma)} \cdot CP^a(d\gamma, d\mu)$$

$$= \frac{1}{Z^a} \int_{\Gamma} 1_{B(a,-\gamma,\varepsilon)} \circ \mathfrak{M}(\mu) \mu F(\mu) \frac{d\mu}{\mu(\Gamma) + 1} \cdot CP^a(d\gamma, d\mu)$$

$$= \frac{1}{Z^a} \int_{\Gamma} F(\mu) \left( \frac{1}{\mu(\Gamma) + 1} \cdot \int_{B(a,(-\gamma,\varepsilon)} \circ \mathfrak{M}(\mu) \rho(d\gamma) \right)$$

Therefore$$\frac{d(P^a^-)}{dP}(\mu) = \frac{1}{Z^a} \frac{1}{\mu(\Gamma) + 1} \cdot \int_{B(a,(-\gamma,\varepsilon))} \rho(d\gamma)$$

where $Z^a$ is the renormalising constant $Z^a := P^a(\mathfrak{M} \in B(a,\varepsilon))$.

Now we pass to the limit as $\varepsilon \to 0$ and check that $\frac{d(P^a^-)}{dP}$ converges. Clearly,
\( \int_{B(a-2M_1(\mu), \varepsilon)} \rho(\gamma) d\gamma = O(\varepsilon^d) \) where \( \rho \) is the density of the intensity measure of \( P_\mu \). On the other side, since the law of \( M_1 \) under \( P_\mu \) is absolutely continuous, \( Z_{P_\mu}^{a, \varepsilon} \) is also of order \( \varepsilon^d \) as \( \varepsilon \downarrow 0 \). This completes the proof of Proposition 2.5.

Proof. of Proposition 2.5.

Assume that \( Q \) satisfies (*) We have to show that

\[
\tilde{Q} := \frac{\mu(\Gamma) + 1}{\rho(c - 2M_1(\mu))} Q^-.
\]

is indeed proportional to the Poisson process \( P_\rho \), or equivalently that \( \tilde{Q} \) satisfies Mecke’s formula (2.13). Therefore we compute the integral of any test function \( F \in B(\Gamma \times M(\Gamma)) \) under the measure \( (\rho \otimes \tilde{Q}) \circ (\varsigma_+)^{-1} \):

\[
\begin{align*}
\int_{\Gamma \times M(\Gamma)} F(\gamma', \mu + \delta_\gamma) \rho(\gamma') \tilde{Q}(d\mu) \\
= \int_{\Gamma \times M(\Gamma)} F(\gamma', \mu + \delta_\gamma) \frac{\mu(\Gamma) + 1}{\rho(c - 2M_1(\mu))} Q^-(d\mu) \rho(\gamma') \\
\overset{\text{(2.12)}}{=} \int_{\Gamma^2 \times M(\Gamma)} F(\gamma', \mu + \delta_\gamma - \delta_\gamma) \frac{\mu(\Gamma) + 1}{\rho(c - 2M_1(\mu))} Q(d\mu) \rho(\gamma') \\
= \int_{\Gamma^2 \times M(\Gamma)} F(\gamma', \mu + \delta_\gamma - \delta_\gamma) \frac{\rho(\gamma)}{\rho(\gamma')} C_Q(d\gamma, d\mu) d\gamma',
\end{align*}
\]

since \( Q \) is concentrated on point measures with fixed first moment equal to \( a \). Now define the function \( \tilde{F} \in B(\Gamma^2 \times M(\Gamma)) \) by

\[
\tilde{F}(\gamma'', \gamma', \mu) := \frac{\rho(\gamma')}{\rho(\gamma'' + \gamma')} F(\gamma', \mu - \delta_\gamma'').
\]

The above identity rewrites

\[
\begin{align*}
\int_{\Gamma^2 \times M(\Gamma)} F(\gamma', \mu + \delta_\gamma) \rho(\gamma') \tilde{Q}(d\mu) \\
= \int_{\Gamma^2 \times M(\Gamma)} \tilde{F} \circ \mathcal{S}(\gamma', \gamma', \mu) C_Q(d\gamma, d\mu) d\gamma' \\
= \int_{\Gamma^2 \times M(\Gamma)} \tilde{F} \circ \mathcal{S}(\gamma', \gamma', \mu) \chi_\rho(\gamma, \gamma') C_Q^{(2)}(d\gamma, d\gamma', d\mu) \\
= \int_{\Gamma^2 \times M(\Gamma)} F(\gamma', \mu - \delta_\gamma) \frac{1}{\rho(\gamma)} C_Q^{(2)}(d\gamma, d\gamma', d\mu) \\
= \int_{\Gamma^2 \times M(\Gamma)} F(\gamma', \mu - \delta_\gamma) \frac{1}{\rho(\gamma)} |\mu|^{(2)}(d\gamma', d\gamma') Q(d\mu) \\
= \int_{\Gamma^2 \times M(\Gamma)} F(\gamma', \mu - \delta_\gamma) \frac{\mu(\Gamma)}{\rho(c - 2M_1(\mu))} (\mu - \delta_\gamma)(d\gamma') \frac{\mu(d\gamma)}{\mu(\Gamma)} Q(d\mu) \\
= \int_{\Gamma \times M(\Gamma)} F(\gamma', \mu) \frac{\mu(\Gamma) + 1}{\rho(c - 2M_1(\mu))} d\gamma' Q^-(d\mu) \\
= \int_{\Gamma \times M(\Gamma)} F(\gamma', \mu) C_Q(d\gamma', d\mu).
\end{align*}
\]
Proof. of Proposition 2.10
Due to the fact that \( Q(\mathcal{M}_1 = a) = 1 \), we can reconstruct \( Q \) from \( Q^- \), or equivalently, \( C'_Q \) from \( C_{Q^-} \):

\[
\int F(\gamma, \mu) C'_Q(d\gamma, d\mu) = \int F(\gamma, \mu - \delta_\gamma) \mu(d\gamma)Q(d\mu) = \int F(\gamma, \mu - \delta_\gamma)((\mu - \delta_\gamma)(\Gamma) + 1) \frac{\mu(d\gamma)}{\mu(\Gamma)}Q(d\mu).
\]

Now, \( \gamma = \mathcal{M}_1(\delta_\gamma) = \mathcal{M}_1(\mu) - \mathcal{M}_1(\mu - \delta_\gamma) = a - \mathcal{M}_1(\mu - \delta_\gamma), Q\text{-a.s..} \) Therefore

\[
\int F(\gamma, \mu) C'_Q(d\gamma, d\mu) = \int F(a - \mathcal{M}_1(\mu), \mu - \delta_\gamma)((\mu - \delta_\gamma)(\Gamma) + 1) \frac{\mu(d\gamma)}{\mu(\Gamma)}Q(d\mu)
= \int F(a - \mathcal{M}_1(\mu), \mu)(\mu(\Gamma) + 1)Q^-(d\mu)
= \int \bar{F}(\mu) C_{Q^-}(d\gamma, d\mu),
\]

where \( \bar{F}(\mu) := \frac{\mu(\Gamma) + 1}{\mu(\Gamma)} F(a - \mathcal{M}_1(\mu), \mu). \)

Remark 2.11. Note that identity (*) is trivially satisfied by the degenerate point process \( \delta_0 \) carrying only the empty configuration. In that case left and right hand sides of (*) vanish. Moreover, since that identity is linear as function of \( Q \), any mixture of solutions of (*) remains a solution of (*). This is the reason why the atomic part on 0 of a solution of (*) can not be quantified by (*) and why we have to consider separately the case \( a = 0 \).

Therefore, if the support of \( Q \) is included in \( \{\mathcal{M}_1 = 0\} \), developing the same arguments as above on its restriction to \( \{0\}^c \) leads to its characterization:

\[
\chi_{\rho} C^{(2)}_Q = (C_Q \otimes d\gamma') \circ \mathcal{G}^{-1} \iff Q(\cdot | \{0\}) = P^0_{\rho}(\cdot | \{0\}).
\]

2.4 Application: Stochastic comparison between the pinned Poisson point process and the unpinned one

Our aim in this subsection is to apply Theorem 2.6 to compare stochastically the density of the points of a pinned Poisson point process \( P^a_{\rho} \) with that of an unpinned Poisson point process \( P_{\rho} \), under specific assumptions on the intensity measure \( \rho \). We first recall the concept of dominance for probability laws on \( \mathbb{N} \).

Definition 2.12. Let \( p \in \mathcal{P}(\mathbb{N}) \) and \( q \in \mathcal{P}(\mathbb{N}) \) be two probability measures on \( \mathbb{N} \). We say that \( p \) dominates \( q \) (or equivalently \( q \) is dominated by \( p \)) if and only if the tails of \( p \) are larger than the tails of \( q \) in the sense that, for any \( j \geq 1 \), we have

\[
p(\{n \in \mathbb{N} : n \geq j\}) \geq q(\{n \in \mathbb{N} : n \geq j\}).
\]

In that case we denote \( p \geq q \) (or \( q \preceq p \)).

Proposition 2.13. 1. Assume that the density function \( \rho \) satisfies on \( \Gamma \):

\[
\exists K > 0 \quad \forall \gamma \in \Gamma, \quad \rho * \rho(\gamma) \leq K \rho(\gamma). \tag{2.13}
\]
Then, for any $a \neq 0$, the law of the number of points of the process $\mathcal{P}_\rho^a$ is dominated by $\text{poi}_{2K}^+$, where $\text{poi}_{2K}^+ \in \mathcal{P}(\mathbb{N}^*)$ denotes the Poisson law conditioned to be positive:

$$\mathcal{P}_\rho^a(\mu(\Gamma) = \cdot) \leq \text{poi}_{2K}^+(\cdot) := \frac{\text{poi}_{2K}(\cdot)}{\text{poi}_{2K}(\mathbb{N}^*)}.$$  \hspace{1cm} (2.14)

Moreover

$$\mathcal{P}_\rho^0(\mu(\Gamma) = \cdot) \leq \text{poi}_{2K}^+(\cdot) := \frac{\text{poi}_{2K}(\cdot)}{\text{poi}_{2K}(\mathbb{N}^*)}. \hspace{1cm} (2.15)$$

2. If $\rho$ satisfies the converse condition

$$\exists \ k > 0 \ \forall \gamma \in \Gamma, \ \rho * \rho(\gamma) \geq k \rho(\gamma), \hspace{1cm} (2.16)$$

then for any $a \neq 0$,

$$\mathcal{P}_\rho^a(\mu(\Gamma) = \cdot) \geq \text{poi}_{2K}^+(\cdot).$$

Proof. We only prove the statement \[2.14\], the proof of \[2.16\] being very similar. Recall that, due to Theorem 2.6, for any positive test function $F$,

$$E_{\mathcal{P}_\rho^a} \left( \int_{\Gamma^2} F(\gamma-\gamma', \gamma', \mu-\delta_\gamma + \delta_{\gamma'} + \delta_{\gamma-\gamma'}) \mu(d\gamma') d\gamma \right) = E_{\mathcal{P}_\rho^a} \left( \int_{\Gamma^2} F(\gamma, \gamma', \mu) \chi_{\rho(\gamma, \gamma') \mu(\gamma)}(d\gamma', d\gamma) \right)$$

By plugging in $G(\gamma, \gamma', \mu) := F(\gamma, \gamma', \mu) \chi_{\rho(\gamma, \gamma')^{-1}}$ we obtain

$$\int_{\Gamma^2} \int_{\Gamma^2} G(\gamma, \gamma', \mu) \mu(\gamma') d\gamma' \mathcal{P}_\rho^a d\mu = \int_{\Gamma^2} \int_{\Gamma^2} G(\gamma, \gamma', \mu) \mu(\gamma) \mu(\gamma') \mathcal{P}_\rho^a d\mu$$

If we consider functionals of the form $G(\gamma, \gamma', \mu) = g(\mu(\Gamma))$ for some measurable map $g : \mathbb{N} \to \mathbb{R}^+$, the right hand side of the equation above becomes

$$\frac{1}{2} \int g(\mu(\Gamma)) \mu(\Gamma)(\mu(\Gamma) - 1) \mathcal{P}_\rho^a d\mu.$$ 

We write the left hand side as

$$\int g(\mu(\Gamma) + 1) \int_{\Gamma} \frac{1}{\rho(\gamma)} \left( \int \rho(\gamma - \gamma') \rho(\gamma') d\gamma' \right) \mu(d\gamma) = \int g(\mu(\Gamma) + 1) \int_{\Gamma} \frac{1}{\rho(\gamma)} \rho(\gamma') \mu(d\gamma').$$

Under assumption \[2.13\] the last term in the formula above is bounded by

$$K \int g(\mu(\Gamma) + 1) \mu(\Gamma) \mathcal{P}_\rho^a d\mu.$$ 

Therefore, we have proven that for any $g \geq 0$,

$$\int g(\mu(\Gamma)) \mu(\Gamma)(\mu(\Gamma) - 1) \mathcal{P}_\rho^a d\mu \leq 2K \int g(\mu(\Gamma) + 1) \mu(\Gamma) \mathcal{P}_\rho^a d\mu,$$

which is equivalent to say that for any $\bar{g}$ such that $\bar{g}(1) = 0$,

$$\int \bar{g}(\mu(\Gamma)) \mu(\Gamma) \mathcal{P}_\rho^a d\mu \leq 2K \int \bar{g}(\mu(\Gamma) + 1) \mathcal{P}_\rho^a d\mu.$$
By choosing $\bar{g} = 1_{\{i\}}$, we obtain

$$P_\rho^a(\mu(\Gamma) = i) \leq 2K P_\rho^a(\mu(\Gamma) = i - 1), \quad \forall i \geq 2.$$ 

Taking $j := i - 1$ and observing that

$$\frac{2K}{j + 1} = \frac{\text{poi}_{2K}(j + 1)}{\text{poi}_{2K}(j)} = \frac{\text{poi}_{2K}^+(j + 1)}{\text{poi}_{2K}^+(j)}, \quad j \geq 1,$$

the statement above can be rewritten as

$$\forall j \geq 1, \quad P_\rho^a(\mu(\Gamma) = j + 1) \text{poi}_{2K}^+(j) \leq P_\rho^a(\mu(\Gamma) = j) \text{poi}_{2K}^+(j + 1).$$

Since $a \neq 0$, $P_\rho^a$ does not carry the zero measure and then $P_\rho^a(\emptyset) = 0$. Thus, we can regard $P_\rho^a(\mu(\Gamma) = \cdot)$ as a measure on $\mathbb{N}^*$. The desired conclusion now follows applying Lemma 2.14 to $p = \text{poi}_{2K}^+$ and $q := P_\rho^a(\mu(\Gamma) = \cdot)$.

**Lemma 2.14.** Let $p, q$ be two probability laws on $\mathbb{N}^*$. Moreover, assume that $p$ is always positive. If

$$\forall j \geq 1, \quad q(j + 1) p(j) \leq q(j) p(j + 1)$$

then $p \succeq q$.

**Proof.** Suppose first that both laws are positive, the general case following with a simple approximation argument. In that case we can rewrite the assumption as

$$\forall j \geq 1, \quad \frac{q(j + 1)}{q(j)} \leq \frac{p(j + 1)}{p(j)} \quad \implies \quad \forall k \geq j \geq 1, \quad \frac{q(k)}{q(j)} \leq \frac{p(k)}{p(j)}.$$ (2.17)

We have to show that for all $j \geq 1$, $\sum_{k \geq j} p(k) \geq \sum_{k \geq j} q(k)$. To do this it is sufficient to show that the function $g$ defined by

$$g : \mathbb{N}^* \to \mathbb{R}^+, \quad g(j) := \frac{\sum_{k \geq j} q(k)}{\sum_{k \geq j} p(k)}$$

is decreasing, and to remark that $g(1) = 1$. To show that $g$ is decreasing we observe that

$$g(j + 1) - g(j) \leq 0 \iff \sum_{k \geq j + 1} q(k) \sum_{l \geq j} p(l) - \sum_{k \geq j + 1} p(k) \sum_{l \geq j} q(l) \leq 0$$

$$\iff p(j) \sum_{k \geq j + 1} q(k) - q(j) \sum_{k \geq j + 1} p(k) \leq 0$$

$$\iff \sum_{k \geq j + 1} \frac{q(k)}{q(j)} \leq \sum_{k \geq j + 1} \frac{p(k)}{p(j)}.$$

This last condition is directly implied by (2.17). □

The following statement provides us the information about the expected number of points of the pinned process.

\[ \text{(continued)} \]
Corollary 2.15. 1. Assuming that condition (2.13) holds true and \( a \neq 0 \). Then
\[
\mathbb{E}_{P_{a\rho}}(\mu(\Gamma) = \cdot) \leq \frac{2K}{1 - e^{-2K}}
\]
Moreover
\[
\mathbb{E}_{P_0\rho}(\mu(\Gamma) = \cdot | \{0\}^c) \leq \frac{2K}{1 - e^{-2K}}
\]
2. Assuming that condition (2.16) holds true and \( a \neq 0 \). Then
\[
\mathbb{E}_{P_{a\rho}}(\mu(\Gamma) = \cdot) \geq \frac{2k}{1 - e^{-2k}}
\]
Moreover
\[
\mathbb{E}_{P_0\rho}(\mu(\Gamma) = \cdot | \{0\}^c) \geq \frac{2k}{1 - e^{-2k}}
\]

Proof. The statement follows immediately from the fact that for a non-negative discrete-valued random variable \( X \) the expectation rewrites as
\[
\mathbb{E}(X) = \sum_{j \geq 1} \mathbb{P}(X \geq j)
\]
and that \( \text{poi}_{2K}(n) = \frac{(2K)^n}{n!} e^{-2K} (1 - e^{-2K}) \).

We will discuss in Section 3.3 several examples of measures \( \rho \) satisfying condition (2.13) and/or condition (2.16).

One can generalize Proposition 2.13 by comparing the random number of points inside of any cone of \( \Gamma \) under the Poisson point process and its pinned version, as follows.

Fix a cone \( \mathcal{K} \) with positive Lebesgue measure. We define a convolution operation \( \ast \) of a function \( \rho \) with itself on the cone \( \mathcal{K} \) as follows:
\[
\rho^{(\mathcal{K})} \ast \rho(\gamma) = \int_{\mathcal{K} \cap (\gamma - \mathcal{K})} \rho(\gamma')\rho(\gamma - \gamma') \, d\gamma' , \quad \gamma \in \mathcal{K}.
\] (2.18)

Let us remark that if \( \gamma \in \mathcal{K} \), then the set \( \mathcal{K} \cap (\gamma - \mathcal{K}) \) has positive Lebesgue measure as well, so that \( \rho^{(\mathcal{K})} \ast \rho(\gamma) > 0 \). We can now express the following result.

Proposition 2.16. Suppose the density function \( \rho \) satisfies:
\[
\exists K > 0 \quad \forall \gamma \in \mathcal{K}, \quad \rho^{(\mathcal{K})} \ast \rho(\gamma) \leq K \rho(\gamma),
\] (2.19)
and let \( \mu(\mathcal{K}) \) be the random number of points of \( \mu \) in \( \mathcal{K} \). Then, for any \( a \neq 0 \), the law of \( \mu(\mathcal{K}) \) under \( P_{a\rho} \) is dominated by \( \text{poi}_{2K}^+ \).

Conversely, if
\[
\exists k > 0 \quad \forall \gamma \in \mathcal{K}, \quad \rho^{(\mathcal{K})} \ast \rho(\gamma) \geq k \rho(\gamma),
\] (2.20)
then, for any \( a \neq 0 \), the law of \( \mu(\mathcal{K}) \) under \( P_{a\rho} \) dominates \( \text{poi}_{2K}^+ \).

Proof. The proof is very similar to the one of Proposition 2.13, therefore it is omitted.
3 Lévy bridge associated with a diffuse jump measure

Our main interest is now to consider pure jump Lévy processes and their bridges, see e.g. [15, 5, 11, 8] for their construction and their application in various frameworks. The canonical space is $\Omega := \mathcal{D}(I; \Gamma)$, the càdlàg paths defined on $I := [0, 1]$ with values in $\Gamma$. So, to rely with the above formalismus we associate canonically to any path $Z \in \Omega$ the (jump) point measure on $\tilde{\Gamma} := I \times \Gamma$ given by

$$\mu_{Z} := \sum_{t: \Delta Z_{t} \neq 0} \delta_{(t, \Delta Z_{t})} \in \mathcal{M}(\tilde{\Gamma}).$$

For the sake of simplicity we only state our results for one-dimensional processes ($d = 1$). Nevertheless they hold also for multidimensional processes because we require the Lévy measure to have a density with respect to the Lebesgue measure.

We suppose in the whole section that the jump measure is finite, which means that we are dealing with compound Poisson processes. The generalization to an infinite jump measure is postponed to the Remark 3.6.

3.1 Characterization of Lévy bridges

We first define how to split a canonical path $Z \in \Omega$ in replacing one of its jumps, say $\Delta Z_{t}$, by two other jumps at other times.

**Definition 3.1 (Path jump splitting).** Let $Z \in \Omega$ be a path and let $\gamma = (t, \Delta Z_{t}) \in \tilde{\Gamma}$ be a jump time and a jump size of $Z$ or with other words, an atom of $\mu_{Z}$. For $\gamma_{1} = (s_{1}, x_{1}) \in \tilde{\Gamma}$ and $\gamma_{2} = (s_{2}, x_{2}) \in \tilde{\Gamma}$ we define the splitting map $\Theta_{\gamma, \gamma_{1}, \gamma_{2}}$ on paths as follows:

$$\Theta_{\gamma, \gamma_{1}, \gamma_{2}}Z = Z - \Delta Z_{t}1_{[t, 1]} + x_{1}1_{[s_{1}, 1]} + x_{2}1_{[s_{2}, 1]}.$$

(3.1)

This transformation corresponds at the level of point measures on $\tilde{\Gamma}$ to the splitting of an atom $\gamma \in \mu_{Z}$ into the two atoms $\gamma_{1}, \gamma_{2}$.

More precisely, we are interested in transformations such that the resulting global jump size of $Z$ stays unchanged. So the new jump sizes, $x_{1}$ and $x_{2}$, have to satisfy $x_{1} + x_{2} = \Delta Z_{t}$. Moreover, choosing times and sizes of the new jumps uniformly at random, we define the following operator.

**Definition 3.2 (Uniform jump split ).** The operator $A$, acting on non negative functionals $F$ on $\tilde{\Gamma} \times \Omega$, is defined by:

$$AF(Z) = \sum_{t: \Delta Z_{t} \neq 0} \int_{\tilde{\Gamma}^{2}} F((t, \Delta Z_{t}), \gamma_{1}, \gamma_{2}, \Theta_{(t, \Delta Z_{t}), \gamma_{1}, \gamma_{2}}Z) \, dx_{1} \delta_{\Delta Z_{t} - x_{1}}(dx_{2}) \, ds_{1} \, ds_{2}$$

where $\gamma_{1} := (s_{1}, x_{1})$ and $\gamma_{2} := (s_{2}, x_{2})$.

This transformation cancels, one after the other, each jump of the path $Z$ and replace it by two jumps whose sizes add up to the size of the removed jump.

**Proposition 3.3.** Let $\mathbb{P}_{\nu}$ be the pure jump Lévy process with Lévy measure $\nu(dx)$ supposed to be finite and diffuse with positive density function $\nu(x)$. Let $\mathbb{E}_{\nu}$ denote the expectation under
Further we divide and multiply by \( \nu \) the right hand-side of \((3.2)\), which ends the proof.

By the definition of the second order Campbell measure, this rewrites to the expression on the bivariate Mecke formula \((2.6)\). We apply the latter and obtain

\[
\nu(x_1 + x_2)\int_{\Gamma_3} F((t, x_1 + x_2), (s_1, x_1), (s_2, x_2), Z) dt \chi_\nu(x_1, x_2) \nu(x_1)\nu(x_2).
\]

Now we change the order of integration so that we first integrate in \( y \) setting \( x = x_1 + x_2 \). Then we have for any non negative test functional \( F \) on \( \Gamma^2 \times \Omega \),

\[
\mathbb{E}_\nu[\mathcal{A}F] = \mathbb{E}_\nu \left[ \sum_{s_1 \neq s_2, \Delta Z_{s_1} \neq 0} \int_{\Gamma} F((t, \Delta Z_{s_1} + \Delta Z_{s_2}), (s_1, \Delta Z_{s_1}), (s_2, \Delta Z_{s_2}), Z) dt \chi_\nu(\Delta Z_{s_1}, \Delta Z_{s_2}) \right]
\]

where the function \( \chi_\nu \) is defined as in \((2.9)\) by \( \chi_\nu(x_1, x_2) := \frac{\nu(x_1 + x_2)}{\nu(x_1)\nu(x_2)} \).

**Proof.** We recognize the expectation of the random sum in the right hand-side as the integral with respect to the second-order factorial Campbell measure \( C^{(2)}_{\nu} \) and follow the same way as in the proof of Proposition \((2.4)\). Starting with the left hand-side, after integrating under \( \delta_{\Delta Z_t - x_1}(dx_2) \), one gets

\[
\mathbb{E}_\nu[\mathcal{A}F] = \int_{\Gamma^3} F((t, \Delta Z_t), (s_1, x_1), (s_2, \Delta Z_t - x_1), Z - \Delta Z_t I_{[t,1]}, x_1 I_{[s_1,1]} + (\Delta Z_t - x_1) I_{[s_2,1]})
\]

\[
dx_1 ds_1 ds_2 \mu_Z(d\gamma)\mathbb{P}_\nu(d\mu_Z).
\]

By Mecke’s formula we can rewrite the integral under the intensity measure of \( \mu_Z(d\gamma) \), that is under \( \nu(y)dydt \)

\[
\int_{\Gamma^3} \int_{\Gamma} \int_{\Gamma} F((t, y), (s_1, x_1), (s_2, y - x_1), Z + x_1 I_{[s_1,1]} + (y - x_1) I_{[s_2,1]})
\]

\[
dx_1 ds_1 ds_2 \nu(y) dy dt \mathbb{P}_\nu(d\mu_Z).
\]

Now we change the order of integration so that we first integrate in \( y \) and then we change the variable setting \( y = x_1 + x_2 \). This results to the following expression

\[
\int_{\Gamma^3} \int_{\Gamma} \int_{\Gamma} F((t, x_1 + x_2), (s_1, x_1), (s_2, x_2), Z + x_1 I_{[s_1,1]} + x_2 I_{[s_2,1]})
\]

\[
\nu(x_1 + x_2)dx_2 dt dx_1 ds_1 ds_2 \mathbb{P}_\nu(d\mu_Z).
\]

Further we divide and multiply by \( \nu(x_1)\nu(x_2) \) and recognise the terms which correspond to the function \( \chi_\nu \), and also the intensity measures \( \nu(x_i)dx_i ds_i, i = 1, 2 \), which are involved in the bivariate Mecke formula \((2.6)\). We apply the latter and obtain

\[
\int_{\Gamma^3} \int_{\Gamma} \int_{\Gamma} F((t, x_1 + x_2), (s_1, x_1), (s_2, x_2), Z) dt \chi_\nu(x_1, x_2) \epsilon^{(2)}_{\nu}(d\gamma_1, d\gamma_2, d\mu).
\]

By the definition of the second order Campbell measure, this rewrites to the expression on the right hand-side of \((3.2)\), which ends the proof.

As in Corollary \((2.5)\) we can reformulate this result as the absolute continuity with respect to \( \mathbb{P}_\nu \) of the image measure of \( \mathbb{P}_\nu \) under the splitting operator \( \mathcal{A} \). Choosing test functions in \((3.3)\) of the form

\[
F(\gamma, \gamma_1, \gamma_2, Z) := \varphi(x_1) \frac{1_{\# \{ t : \Delta Z_t \neq 0 \} > 1}}{\# \{ t : \Delta Z_t = 0 \} - 1} \tilde{F}(Z)
\]

14
where $\varphi$ is a probability density on $\Gamma$, and applying $\mathfrak{A}$ we indeed split one randomly chosen jump of any path (having at least two jumps) into two new jumps, the random size of the first one following a law with density $\varphi$. Thus, one obtains the following result.

**Corollary 3.4.** For any test function $\tilde{F}$ for which $\mathfrak{A}\tilde{F}$ is $P_\nu$-integrable,

$$E_\nu \left[ \mathfrak{A}\tilde{F}(Z) \right] = E_\nu \left[ \tilde{F}(Z) D_\nu(Z) \right]$$

(3.3)

where

$$D_\nu(Z) := \frac{1}{\#\{ t : \Delta Z_t \neq 0 \} - 1} \sum_{s_1 \neq s_2 : \Delta Z_{s_1} \neq 0} \varphi(\Delta Z_{s_1}) \chi(\Delta Z_{s_1}, \Delta Z_{s_2}).$$

(3.4)

Following the agenda of the previous section we revisit the identity [15] and prove that indeed it characterizes bridges of the pure jump Lévy process $P_\nu$.

Consider the family $(P_\nu^{x,y}, x, y \in \Gamma)$ of bridges of the Lévy process $P_\nu$ between time 0 and time 1. They can be constructed as a regular version of the family of conditional laws $P_\nu(\cdot | Z_0 = x, Z_1 = y)$, $x, y \in \Gamma$, see [15, Proposition 3.1]. We then obtain the following result.

**Theorem 3.5.** The identity (3.2) remains valid under any bridge $P_\nu^{x,y}$ of the pure jump Lévy process $P_\nu$. Reciprocally, consider a pure jump process $Q$ pinned at time 0 and 1 to two values $x \neq y$, that is $Q(Z_0 = x) = Q(Z_1 = y) = 1$. If the following identity holds

$$E_Q \left[ \mathfrak{A}\Phi \right] =$$

$$E_Q \left[ \sum_{s_1 \neq s_2 : \Delta Z_{s_1} \neq 0} \int I_{\Delta Z_{s_1} \neq 0} \Phi((t, \Delta Z_{s_1} + \Delta Z_{s_2}), (s_1, \Delta Z_{s_1}), (s_2, \Delta Z_{s_2}), Z) dt \chi(\Delta Z_{s_1}, \Delta Z_{s_2}) \right]$$

(3.5)

then $Q$ coincides with the bridge $P_\nu^{x,y}$.

If the pure jump process $Q$ is pinned at time 0 and 1 to the same value $x$ (that is it carries only loops which start and end in $x$) and satisfies Identity (3.5) then

$$Q(\cdot | \#\{ t : \Delta Z_t \neq 0 \} \geq 1) = P_\nu^{x,x}(\cdot | \#\{ t : \Delta Z_t \neq 0 \} \geq 1).$$

With other words, $Q$ and the bridge $P_\nu^{x,x}$ coincide on the set of non constant paths.

**Proof.** To show that bridges of the process $P_\nu$ satisfy formula (3.2) is straightforward by disintegration of $P_\nu$ as mixture of its bridges.

To show that reciprocally, any pinned pure jump process $Q$ which satisfies (3.3) coincides with a bridge of $P_\nu$, we exploit the following duality between bridges of pure jump processes and point processes pinned by their first moment: the point measure $\mu_Z$ has a fixed first moment $\mathfrak{M}_1(\mu_Z) = a$ if and only if the corresponding pure jump process has fixed initial and final values $x$ and $y$ satisfying $x - y = a$. This together with Theorem 2.6 leads to the conclusion.

Since Identity (3.5) is linear as a function of $Q$, and since the integrated bivariate function $\chi_x$ does not depend on the boundary conditions $x$ and $y$, (3.3) eventually characterises the set of all mixtures of bridges $(P_\nu^{x,y}, x, y \in \Gamma)$, called in the literature the **reciprocal class** associated
Approximating Lévy processes whose Lévy measure has an infinite mass by a sequence of compound Poisson processes, one obtains the following generalization of the previous theorem.

**Remark 3.6** Still if its diffuse jump measure is infinite, a pure jump process \( Q \) is in the reciprocal class of \( P_\nu \) if and only if the identity (3.5) holds for all continuous bounded test functions \( \Phi \) on \( \Gamma^3 \times \Omega \) as soon as \( \chi_\nu \) is \( C^{(2)} \)-integrable. Indeed consider, for any \( n \in \mathbb{N} \), the compound Poisson approximation \( Z^n \) obtained from the initial Lévy process \( Z \) by canceling its jumps whose size is smaller than \( \frac{1}{n} : Z^n_t := Z_t \cdot 1_{|\Delta Z_t| > \frac{1}{n}} \). Its Lévy measure is now finite, given by \( \nu^n(dx) = \nu^n(x) dx := \nu(x)1_{|x| > \frac{1}{n}} dx \). and Identity (3.2) holds under \( P_{\nu^n} \). Applying it to the cut-off functions \( F^n(\gamma, \gamma_1, \gamma_2, Z) := \Phi(\gamma, \gamma_1, \gamma_2, Z)1_{|\Delta Z| > \frac{1}{n}} \) where \( \Phi \) is any continuous bounded test function, leads to an identity which converges towards (3.5) when \( n \) grows.

### 3.2 Sampling a Lévy bridge

In this subsection we describe heuristically how to construct a sampler for a Lévy bridge. Indeed, the basic idea is to construct a dynamic on the pure jump path space whose stationary measure would be the law of a Lévy bridge. This generalizes to jump processes some of the results presented in [7, 6] for diffusion processes.

Consider a functional \( \Phi \) of the form

\[
\Phi((t, \Delta Z_t), \gamma_1, \gamma_2, Z) = \left[ F(Z) - F(Z + \Delta Z_t 1_{[t,1]} - x_1 1_{[s_1,1]} - x_2 1_{[s_2,1]}) \right] \varphi(x_1),
\]

where the test functional \( F \) is bounded measurable, the density function \( \varphi \) is rapidly decaying at infinity and as before, \( \gamma_1 := (s_1, x_1) \) and \( \gamma_2 := (s_2, x_2) \). Equation (3.5), satisfied by any bridge of \( P_\nu \), rewrites for such \( \Phi \) as

\[
\mathbb{E}_{P^\nu} \left[ \sum_{t: \Delta Z_t \neq 0} \int_{I^2 \times \Gamma} \left[ F(Z - \Delta Z_t 1_{[t,1]} + x_1 1_{[s_1,1]} + x_2 1_{[s_2,1]}) - F(Z) \right] \varphi(x_1) dx_1 ds_1 ds_2 
+ \sum_{s_1 \neq s_2: \Delta Z_{s_1}, \Delta Z_{s_2} \neq 0} \varphi(\Delta Z_{s_1}) \chi_\nu(\Delta Z_{s_1}, \Delta Z_{s_2})
\left[ \int_t \left[ F(Z + (x_1 + x_2) 1_{[t,1]} - x_1 1_{[s_1,1]} - x_2 1_{[s_2,1]} - F(Z) \right] dt \right] = 0.
\]

This identity suggests that the bridges \( P^\nu \) can be interpreted as the invariant law of a Markov process on the path space regulated by two mechanism: either jumps split/fragmentate (first term) or jumps coalesce (second term). More precisely, if \( Z \) is the current state of the process, then

- Each jump \((t, Z_t)\) of the path \( Z \) splits at rate 1; when this happens, the jump at \( t \) is removed, and is replaced by two new jumps \((s_1, x_1)\) and \((s_2, x_2)\) which are sampled according to the following rules.
  - The jump times \( s_1, s_2 \) are chosen uniformly at random in \([0, 1]^2\).
The first jump size \( x_1 \) is sampled from the probability law with density \( \varphi \) and the second jump size is set to be \( x_2 := \Delta Z_t - x_1 \).

Each ordered pair \((s_1, \Delta Z_{s_1}), (s_2, \Delta Z_{s_2})\) of jumps of \( Z \) coalesce at rate \( \varphi(t) \chi_{\nu}(Z_{s_1}, Z_{s_2}) \); when this happens, the two jumps are removed from \( Z \) and replaced by a single jump \((t, \Delta Z_t)\) sampled according to the following rules.

- The jump time \( t \) is sampled uniformly at random in \([0, 1]\).
- The jump size is the sum of the sizes of the removed jumps: \( \Delta Z_t := \Delta Z_{s_1} + \Delta Z_{s_2} \).

### 3.3 Stochastic comparison between Lévy bridges

In this section we apply the above results to investigate domination properties for bridges of pure jump Lévy processes.

We consider Lévy measures having the form \( \nu(dx) = \lambda f(x)dx \) where the constant \( \lambda > 0 \) encodes the intensity of the jumps per unit interval, and the function \( f \) on \( \mathbb{R} \) is a probability density encoding the distribution of the jumps. It then corresponds to the assumption made in the beginning of Section 2.2. Thus, supposing the density \( f \) to be positive, domination conditions (2.13), respectively (2.16), rewrite:

\[
\exists K < \infty, \sup_{x \in \mathbb{R}} \frac{f \ast f(x)}{f(x)} \leq K, \quad \text{resp.} \quad \exists k > 0, \inf_{x \in \mathbb{R}} \frac{f \ast f(x)}{f(x)} \geq k. \tag{3.6}
\]

Our aim is to compare the law of the number of jumps of a Lévy bridge with a Poisson distribution. We consider two specific families of Lévy bridges: their Lévy measures are of Cauchy-type with densities \( f_{\alpha} \) or of symmetric exponential-type with densities \( g_{\beta} \), where:

\[
f_{\alpha}(y) := \frac{r_{\alpha}}{1 + |y|^\alpha}, \quad \alpha > 1, \quad \text{and} \quad g_{\beta}(y) := r_{\beta} e^{-|y|^\beta}, \quad \beta > 0.
\]

Here \( r_{\alpha} > 0, r_{\beta} > 0 \) denote the normalising constants.

#### Stochastic comparison for the Cauchy-type family

We now prove that both inequalities in (3.6) are satisfied by this family of jump laws or equivalently, we prove that the function \( H_{\alpha}(x) := \frac{f_{\alpha} \ast f_{\alpha}(x)}{f_{\alpha}} \) is uniformly bounded from above and from below (by a positive constant). First notice the integral representation:

\[
H_{\alpha}(x) = \int_{\mathbb{R}} h_{\alpha}(x, y) dy, \quad \text{with} \quad h_{\alpha}(x, y) := \frac{1 + |x|^\alpha}{(1 + |y + \frac{x}{2}|^\alpha)(1 + |y - \frac{x}{2}|^\alpha)}.
\]

Since the function \( h_{\alpha} \) is symmetric in \( x \) and \( y \), it is enough to consider \( h_{\alpha}(x, y) \) for \( x > 0, y > 0 \).

**Upper bound.** Since \( H_{\alpha} \) is continuous it is bounded from above on the interval \([0, 1]\). So let us consider \( x \in [1, +\infty[. \) We decompose \( H_{\alpha}(x) \) into two integrals:

\[
\frac{1}{2} H_{\alpha}(x) = \int_0^{x/2} h_{\alpha}(x, y) dy + \int_{x/2}^{+\infty} h_{\alpha}(x, y) dy.
\]
Now
\[
\int_0^{x/2} h_\alpha(x, y) \, dy \leq \frac{1 + x^\alpha}{1 + (x/2)^\alpha} \int_0^{x/2} \frac{dz}{1 + z^\alpha} < \frac{2^\alpha (1 + x^\alpha)}{2^\alpha + x^\alpha} \int_0^{+\infty} \frac{dz}{1 + z^\alpha}
\]
which is uniformly bounded for \( x \in [1, +\infty] \) since \( \alpha \) is supposed to be larger than 1. Similarly
\[
\int_{x/2}^{+\infty} h_\alpha(x, y) \, dy \leq \frac{1 + x^\alpha}{1 + (x/2)^\alpha} \int_{x/2}^{+\infty} \frac{1}{1 + (y - x/2)^\alpha} \, dy = \frac{2^\alpha (1 + x^\alpha)}{2^\alpha + x^\alpha} \int_0^{+\infty} \frac{dz}{1 + z^\alpha}
\]
which is uniformly bounded for \( x \in [1, +\infty] \).

**Lower bound.** As before, it is enough to consider \( x \in [1, +\infty] \).
\[
\frac{1}{2} H_\alpha(x) \geq \int_0^{x/2} h_\alpha(x, y) \, dy \geq \frac{1 + x^\alpha}{1 + x^\alpha} \int_0^{x/2} \frac{dz}{1 + z^\alpha} \geq \int_0^{1/2} \frac{dz}{1 + z^\alpha} > 0
\]
Hereby we have shown that \( \nu_\alpha = \lambda f_\alpha(x) \, dx \) satisfies both inequalities \((2.13)\) and \((2.16)\) for some constants \( K_\alpha \) and \( k_\alpha \). Due to Proposition 2.13, we conclude that the distribution of the number of jumps for any bridge of a Lévy process with Cauchy-type jump distribution, conditioned to have at least one jump, is stochastically equivalent with a Poisson law conditioned to stay positive.

For \( \alpha = 2 \) the law of the jumps is a Cauchy distribution with density \( f_2(y) = \frac{1}{\pi(1 + y^2)} \).

Thus \( f_2 * f_2(y) = \frac{2}{\pi(1 + y^2)} \) and we obtain the explicit bounds: \( \frac{1}{2} \leq H_\alpha(x) \leq 2 \). Therefore, as application of Proposition 2.13 and Corollary 2.15, the following holds.

**Proposition 3.7.** The distribution of the number of jumps for any bridge of a Lévy process with Cauchy jump distribution, supposing it is larger than 0, is stochastically dominated by (resp. dominates) a Poisson law with parameter \( 4\lambda \) (resp. \( \lambda \)) conditioned to stay positive. Therefore its expected number belongs to \([\frac{\lambda}{1-e^{-x}}, \frac{4\lambda}{1-e^{-4x}}]\). For \( \lambda = 1 \), this interval is equal to \([1.58; 4.07]\).

Notice once more that these comparisons do not depend on the height of the bridge, as soon as it differs from 0.

**Stochastic comparison for the symmetric exponential-type family.** We now prove that (only) the second inequality in \((3.6)\) is satisfied by the family of jump densities \( g_\beta \) or equivalently, we prove that the function \( G_\beta(x) := \frac{g_\beta * g_\beta}{g_\beta}(x) \) is uniformly bounded from below by a positive constant. First notice the integral representation:
\[
G_\beta(x) = e^{[x/\beta]} \int_{\mathbb{R}} g_\beta(x, y) \, dy,
\]
where \( g_\beta(x, y) := e^{-|y+x/2|^2/\beta} e^{-|y-x/2|^2/\beta} \). Remark that the function \( g_\beta(x, y) \) is even in \( y \) and symmetric in \( x \).

**First case:** \( 0 < \beta < 1 \). The graph of \( y \mapsto g_\beta(x, y) \) is bimodal for \( x \neq 0 \) and becomes unimodal for \( x = 0 \). The value of \( G_\beta \) at \( x = 0 \) is \( G_\beta(0) = \frac{2}{\beta^{2/\beta}} \Gamma(1/\beta) \). On the compact interval \([-1/2, 1/2]\), the continuous map \( G_\beta \) is bounded from below by a positive constant.
For $|x| > 1/2$ one can inscribe under the graph of $y \mapsto \tilde{g}_\beta(x, y)$ equal triangles with vertices at $A_+ := (x/2, e^{-|x|^\beta})$ and $A_- := (-x/2, e^{-|x|^\beta})$, having as sides the tangents at each of the vertices $A_+, A_-$ and with height $h = e^{-|x|^\beta}$. Then

$$\inf_{|x| > 1/2} G_\beta(x) \geq \inf_{|x| > 1/2} e^{|x|^\beta}(\frac{|x|^{1-\beta}}{\beta} + \frac{|x|}{2}) \geq \frac{2^\beta}{\beta} + \frac{1}{2}.$$ 

This shows that the function $G_\beta$ is uniformly bounded from below by a positive constant.

**Second case:** $\beta \geq 1$. The graph of $y \mapsto \tilde{g}_\beta(x, y)$ becomes unimodal, and since the function is symmetric we consider only the case $x > 0$. The unique maximum of this function is at the point $x/2$. Analysing the integrals over $[0, x/2]$ and $[x/2, +\infty)$ for $0 \leq x \leq 1$ and $x > 1$ and using the respective asymptotical behaviour of the incomplete Gamma function, we get that $G_\beta(x)$ is again uniformly bounded from below by a positive constant $k_\beta$. Due to Proposition 2.13 we conclude that the distribution of the number of jumps for any bridge of a Lévy process with symmetric exponential-type jump distribution, conditioned to one jump, stochastically dominates a Poisson law with parameter $2\lambda k_\beta$ conditioned to stay positive.

For $\beta = 1$ the law of the jumps is a Laplace distribution with density $g_1(y) = e^{-|y|}/2$. We compute explicitly $G_1(x) = \frac{1}{2}(1 + |x|)$ and obtain as lower bound $k_1 = 1/2$.

For $\beta = 2$ the law of the jumps is the standard normal distribution with density $g_2(y) = e^{-y^2}/\sqrt{\pi}$. We compute explicitly $G_2(x) = \frac{1}{\sqrt{2\pi}}e^{-x^2}$ and obtain as lower bound $k_2 = 1/\sqrt{2}$.

Thus, as application of Proposition 2.13 and Corollary 2.15, the following holds.

**Proposition 3.8.** The distribution of the number of jumps for any bridge of a Lévy process with Laplace (resp. standard Gaussian) jump distribution, conditioned to have at least one jump, stochastically dominates a Poisson law with parameter $\lambda$ (resp. $\sqrt{2}\lambda$) conditioned to stay positive. Therefore its expected number is not less than $\lambda/(1 - e^{-\lambda})$ (resp. $\sqrt{2}\lambda(1 - e^{-\sqrt{2}\lambda})$). For $\lambda = 1$ these bounds are equal to 1.58 (resp. 1.07).

Once more, it is remarkable that these bounds do not depend of the height of the bridge.

## 4 Periodic Ornstein-Uhlenbeck processes

We now generalize some result of the previous section to the case of linear diffusion driven by a Lévy process. Introducing a damping force in the random dynamics, we consider the real-valued Langevin equation with damping parameter $c \in \mathbb{R}^+$

$$dX_t = -cX_t \, dt + dZ_t, \quad t \in [0, 1]$$

(4.1)

where $Z$ is the Lévy process with law $\mathbb{P}_\nu$. The measure $\nu$ is as before a diffuse finite Lévy measure on $\mathbb{R}^*$. Suppose moreover that the solution of this SDE is periodized, that is satisfies the boundary conditions $X_0 = X_1$. This process, studied in [13] [14], is called periodic Ornstein-Uhlenbeck with parameter $c$ and background driving Lévy process $Z$, short PerOU-Lévy process. We denote its law by $P_{\nu,c}^\text{PerOU}$.

Notice that, if one replaces in (1.1) the pure jump process $Z$ by a Brownian motion, one recovers the known periodic Ornstein-Uhlenbeck process, whose properties as a mixture of Ornstein-Uhlenbeck bridges are discussed in [15] Theorem 5.1. A review of its semimartingale properties can be found in [17].
Indeed the periodic solution of (4.1) is the image measure of $\mathbb{P}_\nu$ under the map $X^c : \mathbb{D}([0, 1]; \mathbb{R}) \to \mathbb{D}([0, 1]; \mathbb{R})$ given by:

\[
X^c_0(Z) = X^c_1(Z) = \frac{1}{e^c - 1} \int_0^1 e^{cs} dZ_s,
\]

\[
X^c_t(Z) = e^{-ct} X^c_0(Z) + e^{-ct} \int_0^t e^{cs} dZ_s.
\]

We would like to exhibit an identity generalizing (3.5) satisfied by the PerOU-Lévy process. To this aim we generalize the former operators given in Definitions 3.1 and 3.2 and introduce new time-weighted operators $\Theta^c_{\gamma_1, \gamma_2}$ and $\mathfrak{A}^c$ which take into account the $c$-damping of the paths. They are defined by composing $\Theta^c_{\gamma_1, \gamma_2}$ and $\mathfrak{A}$ with the map $X^c$. More precisely, for any $\gamma = (t, \Delta Z_t) \in [0, 1] \times \mathbb{R}^*$ jump time and jump size of $Z$, any $\gamma_1 = (s_1, x_1) \in [0, 1] \times \mathbb{R}^*$ and $\gamma_2 = (s_2, x_2) \in [0, 1] \times \mathbb{R}^*$, we introduce the time-weighted path jump splitting by

\[
\Theta^c_{\gamma_1, \gamma_2}(Z) = Z + X^c(-\Delta Z_t 1_{[t, 1]} + x_1 1_{[s_1, 1]} + x_2 1_{[s_2, 1]}).
\]

Randomizing time and size of the new jumps, one define the following operator on positive test functions $F$ defined on $([0, 1] \times \mathbb{R}^*)^3 \times \Omega$:

\[
\mathfrak{A}^c F(Z) := \int_{([0, 1] \times \mathbb{R}^*)^3} F(\gamma, \gamma_1, \gamma_2, \Theta^c_{\gamma_1, \gamma_2} Z) dx_1 \delta_{\Delta Z_{s_1} - x_1} dx_2 ds_1 ds_2 \mu_Z(d\gamma).
\]

**Proposition 4.1.** Let $P^\text{OU}_{\nu, c}$ be the periodic Ornstein-Uhlenbeck process with parameter $c$ driven by the Lévy process $Z$ with Lévy measure $\nu$. It satisfies the following identity for any positive test functions $F$:

\[
E_{P^\text{OU}_{\nu, c}} [\mathfrak{A}^c F] =
\]

\[
E_{P^\text{OU}_{\nu, c}} \left[ \sum_{s_1 \neq s_2; \Delta Z_{s_1} \neq 0; \Delta Z_{s_2} \neq 0} \chi_\nu(\Delta Z_{s_1}, \Delta Z_{s_2}) \int_0^1 F((t, \Delta Z_{s_1} + \Delta Z_{s_2}), (s_1, \Delta Z_{s_1}), (s_2, \Delta Z_{s_2}), Z) dt \right]
\]

where $\chi_\nu$ is the reciprocal characteristic associated with the measure $\nu$, given as before by (3.2).

**Proof.** By using the linearity of the map $X^c$

\[
E_{P^\text{OU}_{\nu, c}} [\mathfrak{A}^c F] = E_{\nu} [\mathfrak{A}(F \circ X^c)].
\]

Applying identity (3.2) under $\mathbb{P}_\nu$,

\[
E_{\nu} [\mathfrak{A}(F \circ X^c)] =
\]

\[
E_{\nu} \left[ \sum_{s_1 \neq s_2; \Delta Z_{s_1} \neq 0; \Delta Z_{s_2} \neq 0} \int I F((t, \Delta Z_{s_1} + \Delta Z_{s_2}), (s_1, \Delta Z_{s_1}), (s_2, \Delta Z_{s_2}), X^c(Z)) dt \chi_\nu(\Delta Z_{s_1}, \Delta Z_{s_2}) \right]
\]

Since $\mu_{X^c} = \mu_Z$ we can rewrite the right hand side of the previous equation as the right hand side of (4.2).
