Abstract

The complete set of static screening masses is determined for the SU(2) Higgs model from one-loop coupled gap equations. Results from the version, containing scalar fields both in the fundamental and adjoint representations are compared with the model arising when the integration over the adjoint scalar field is performed. A non-perturbative and non-linear mapping between the couplings of the two models is proposed, which exhibits perfect decoupling of the heavy adjoint scalar field. Also the alternative of a gauge invariant mass resummation is investigated in the high temperature phase.

1 Introduction

The finite temperature SU(2) Higgs model was extensively studied in recent years in connection with the electroweak phase transition (EWPT) and baryon asymmetry generation in the standard model (see Ref. [1] for a review). Considerable progress was achieved in understanding the thermodynamics of the phase transition with the help of the method of dimensional reduction. In this approach the superheavy modes (i.e. the non-zero Matsubara modes with typical mass $\sim 2\pi T$) and the heavy $A_0$ field (with a mass $\sim gT$) are integrated out and the thermodynamics is described by an effective theory, the 3d SU(2) Higgs model [2, 3, 4]. The properties of the phase transition and the screening masses were studied in great detail using lattice Monte-Carlo simulations of the reduced model [5, 6, 7, 8, 9] and also by Dyson-Schwinger (DS) technique in the full 4d theory [10, 11] as well as in the effective 3d theory [12]. Lattice Monte-Carlo simulations predict that the line of first order transitions ends for some Higgs mass $m_H = m_H^c$ [6, 8, 9]. The same conclusion was obtained using the DS approach in Ref. [12] and the value of the critical mass $m_H^c$ was found to be close to the prediction of Monte-Carlo simulations. Though, the validity of one-loop gap equations was critically questioned [13, 14], a recent two-loop calculation [15] has
demonstrated that it is not an accident that the results of the one-loop level analysis are fairly close to the conclusions of the numerical simulations.

The possibility of dimensional reduction is based on the fact that in the full model there are different well separated mass scales \( g^2 T \ll g T \ll 2 \pi T \) for small couplings \( g \). Recent 4d Monte-Carlo simulations of the finite temperature \( SU(2) \) Higgs model \([10, 17]\) provide good non-perturbative tests for the validity of dimensional reduction. A detailed discussion of relating 4d and 3d results was published very recently in Ref. \([18]\).

The purpose of the present paper is twofold. First, we would like to provide some non-perturbative evidence for the decoupling of the \( A_0 \) field from the gauge + higgs dynamics in the vicinity of the phase transition. We are going to solve a coupled set of gap equations for the 3d fundamental + adjoint Higgs model. This model emerges when the non-static modes are integrated out in the full finite temperature Higgs system. Its predictions for the screening masses will be compared with those obtained by Buchmüller and Philipsen (BP) \([12]\) in the 3d Higgs model (with only one scalar field in the fundamental representation) using the same technique. The main result of our investigation is a proposition for a non-perturbative and non-linear mapping between the two models ensuring quantitative agreement between the screening masses in a wide temperature range on both sides of the transition. This high quality evidence for the decoupling of the \( A_0 \) field at the actual finite mass ratios presumes, however, the knowledge of the "exact" value of the Debye screening mass, since for the proposed mapping its non-perturbatively determined value turns out to be essential.

Second, we wish to investigate the symmetric phase in more detail. There the Higgs and the Debye screening masses are both of the same order of magnitude \( \sim g T \) and thus in that regime there is no a priori reason for the \( A_0 \) field to decouple. This circumstance makes the quantitative relation of the screening masses calculated in the 3d fundamental + adjoint Higgs model particularly interesting in the high-T phase. Here we are going to apply two different resummation techniques and check to what extent persists a non-perturbative mass hierarchy in this part of the spectra.

All calculations of this paper are performed at 1-loop accuracy, but the above mentioned signal \([15]\) for the good numerical convergence of the masses determined in the DS-scheme gives us confidence that the effects we find will appear also in improved treatments.

The presentation of our investigation proceeds as follows: in Section 2 we derive the coupled set of gap equations for the 3d fundamental + adjoint Higgs model and discuss some problems related to the formal decoupling of the adjoint Higgs-field, when its screening mass goes to infinity. In Section 3 we solve the coupled set of these equations numerically and estimate the variation in the screening masses and some critical parameters due to the presence of the adjoint Higgs field. In Section 4 we study the screening masses using an alternative gauge invariant resummation scheme, restricted in applicability to the symmetric phase. Finally, Section 5 presents our conclusions.

2 The extended gap equations

The Lagrangian of the three dimensional \( SU(2) \) fundamental + adjoint Higgs model is \([12, 3]\)

\[
L^{3D} = Tr \left[ \frac{1}{2} F_{ij} F_{ij} + (D_i \Phi)^+ (D_i \Phi) + \mu^2 \Phi^+ \Phi + 2 \lambda (\Phi^+ \Phi)^2 \right] + \frac{1}{2} (D_i \vec{A}_0)^2 + \frac{1}{2} \mu^2 \vec{A}_0^2 + \frac{\lambda A_0^2}{4} (\vec{A}_0^2)^2 + 2 c \vec{A}_0^2 Tr \Phi^+ \Phi, \tag{1}
\]
where

\[ \Phi = \frac{1}{2} (\sigma_1 + i \vec{\pi} \vec{\tau}), \quad D_i \Phi = (\partial_i - ig W_i) \Phi, \quad W_i = \frac{1}{2} \vec{\tau} \vec{W}_i. \]  

(2)

The relations between the parameters of the 3d theory and those of the 4d theory are derived at 1-loop level perturbatively [3]:

\[ g^2 = g^2_{4d} T, \quad \lambda = \left( \lambda_{4d} + \frac{3}{128 \pi^4} g^4_{4d} \right) T, \quad \lambda_\Lambda = \frac{17}{48 \pi^4} g^4_{4d} T, \]  

(3)

\[ c = \frac{1}{8} g^2_{4d} T, \quad \mu_D^2 = \frac{5}{6} g^2_{4d} T^2, \quad \mu^2 = \left( \frac{3}{16} g^2_{4d} + \frac{1}{3} \lambda_{4d} \right) T^2 - \frac{1}{7} \mu^2_{4d}. \]

If the integration over the \( A_0 \) adjoint Higgs field is performed we obtain the model investigated in [12] with parameters \( \bar{g}, \bar{\lambda}, \bar{\mu} \). These couplings of the reduced theory are related to the parameters of the 3d fundamental + adjoint Higgs theory through the following relations:

\[ \bar{g}^2 = g^2 \left( 1 - \frac{g^2}{24 \pi \mu_D} \right), \quad \bar{\lambda} = \lambda - \frac{3c^2}{2\pi \mu_D}, \quad \bar{\mu} = \mu^2 - \frac{3c\mu_D}{2\pi}. \]

(4)

In particular, we note that the \( \bar{\mu} \) scale serves as the temperature scale of the fully reduced system, while \( \mu \) is the scale for the system containing both the fundamental and the adjoint scalars. The two are related perturbatively by a constant shift.

In order to perform the actual calculations in the broken phase it is necessary to shift the Higgs field, \( \sigma \to v + \sigma' \). After this shift and the gauge-fixing (the gauge fixing parameter is denoted by \( \xi \)) the Lagrangian including the ghost terms assumes the form

\[ L = \frac{1}{4} \bar{F}_{\mu\nu} \bar{F}^{\mu\nu} + \frac{1}{2\xi} (\partial_\mu \bar{W}_\mu)^2 + \frac{1}{2} m_0^2 \bar{W}_\mu^2 \]

\[ + \frac{1}{2} (\partial_\mu \sigma')^2 + \frac{1}{2} M_0^2 \sigma'^2 + \frac{1}{2} (\partial_\mu \vec{\pi})^2 + \xi \frac{1}{2} m_0^2 \vec{\pi}^2 \]

\[ + \frac{g^2}{4} v \sigma' \bar{W}_\mu^2 + \frac{g}{2} \bar{W}_\mu \cdot (\vec{\pi} \partial_\mu \sigma' - \sigma' \partial_\mu \vec{\pi}) + \frac{g}{2} (\bar{W}_\mu \times \vec{\pi}) \cdot \partial_\mu \vec{\pi} \]

\[ + \frac{g^2}{8} \bar{W}_\mu^2 (\sigma'^2 + \vec{\pi}^2) + \lambda v \sigma' (\sigma'^2 + \vec{\pi}^2) + \lambda (\sigma'^2 + \vec{\pi}^2)^2 \]

\[ + \frac{1}{2} (D_i \vec{A}_0)^2 + \frac{1}{2} m_{D0}^2 \vec{A}_0^2 + \frac{\lambda A}{4} (\vec{A}_0^2)^2 + 2cv \sigma' \vec{A}_0^2 + c A \vec{A}_0^2 (\sigma'^2 + \vec{\pi}^2) \]

\[ + \partial_\mu \vec{c} \cdot \partial_\mu \vec{c} + \xi m_0^2 \vec{c} \vec{c} \]

\[ + g \partial_\mu \vec{c} \cdot (\vec{W}_\mu \times \vec{c}) + \xi \frac{g^2}{4} v \sigma' \vec{c} \cdot \vec{c} + \xi \frac{g^2}{4} v \vec{c} \cdot (\vec{\pi} \times \vec{c}) + \frac{1}{2} \mu^2 v^2 + \frac{1}{4} \lambda v^4 \]

\[ + \frac{1}{2} (\mu^2 + \lambda v^2)(\sigma'^2 + \vec{\pi}^2) + v(\mu^2 + \lambda v^2) \sigma', \]

(5)

where the following notations were introduced for the tree-level masses: \( m_0^2 = \frac{1}{4} g^2 v^2 \) (the vector boson mass), \( M_0^2 = \mu^2 + 3\lambda v^2 \) (the Higgs mass) and \( m_{D0}^2 = \mu_D^2 + 2cv^2 \) (the Debye mass). The last two terms of (5) arise from the Higgs potential after the shift in the Higgs field \( \sigma \). For \( \mu^2 < 0 \), they vanish if one expands around the classical minimum \( v^2 = -\mu^2/\lambda \). In general, however, these terms have to be kept [12].

In order to obtain the coupled gap equations one replaces the tree-level masses by the exact masses

\[ m_0^2 \to m^2 + \delta m^2, \quad M_0^2 \to M^2 + \delta M^2, \quad m_{D0}^2 \to m_D^2 + \delta m_D^2. \]

(6)
and treats the differences $\delta m^2 = m_0^2 - m^2$, $\delta M^2 = M_0^2 - M^2$, $\delta m_D^2 = m_D^2 - m_0^2$ as counterterms. The exact Goldstone and ghost masses are both equal to $\sqrt{\xi} m$, where $m$ is the exact gauge boson mass. The gauge invariance of the self-energies of the Higgs and gauge bosons is ensured by introducing appropriate vertex resummations. Their explicit formulae can be found in \[12\]. In the present extended model, a resummation of the Higgs-$A_0$ vertex would be also necessary if the gauge invariance of the $A_0$ self-energy is to be ensured. Then the only source of the gauge dependence which would remain is the equation for the vacuum expectation value $v$.

All these resummations are equivalent to work with the following gauge invariant Lagrangian:

$$L_3 = \frac{1}{4} F_{ij} F_{ij} + \text{Tr} \left( (D_i \Phi)^+ D_i \Phi - \frac{1}{2} M^2 \Phi^+ \Phi \right) + \frac{1}{8} (M_0^2 - \frac{8cm^2}{g^2}) A_0^2 + \frac{g^2 M^2}{4m^2} \text{Tr} (\Phi^+ \Phi)^2 + 2c A_0^2 \text{Tr} \Phi^+ \Phi.$$  \tag{7}

In this Lagrangian one shifts the Higgs field around its classical minimum $\sigma \rightarrow \sigma' + \frac{2m}{g}$ and adds the corresponding gauge fixing and ghost terms \[12\]. Shortly, we shall argue that the $A_0$-Higgs vertex resummation arising from the replacement of $v$ by $2m/g$ when the scalar field is shifted in the last term of the above Lagrangian destroys the mass-hierarchy between the heavy $A_0$ and the light gauge and Higgs fields. Therefore in this paper we have to give up the full gauge independence of the resummation scheme. The numerical solution to be presented below shows that the gauge dependence of the $A_0 - \Phi$ vertex in our resummation scheme introduces only a minor additional gauge dependence beyond that of the equation for the vacuum expectation value \[12\] appearing below in Eq. (14).

The coupled set of gap equations is constructed from that of Ref. \[12\] by adding the contributions due to the presence of the adjoint Higgs field. The self-energy contributions for the 3d fundamental Higgs and for the 3d adjoint Higgs model were already calculated in \[12\] and \[19\], respectively. Below we list only the additional contributions to the self-energies, which all contain at least one $A_0 - \Phi$ vertex (the corresponding diagrams are listed in the Appendix A). We emphasize once again that no resummation of the $A_0 - \Phi$ vertex was applied.

The additional contribution to the self-energy of the $A_0$ field coming from Higgs, Goldstone, gauge and ghost fields (diagrams a-i) is

$$\delta \Pi_{A_0}^{H.G.gh} (p, m, M, m_D) = - \frac{4c v^2 (\mu^2 + \lambda v^2)}{M^2} + \frac{3c g v}{\pi} \left( \frac{M}{4m} + \frac{m^2}{M^2} \right) - \frac{cM}{2\pi} + \frac{3\sqrt{\xi}}{4\pi} (gv - 2m)$$
$$+ \frac{4c^2 v^2}{\pi} \left[ \frac{3 m_D}{2 M^2} - \frac{1}{p} \arctan \frac{p}{m_D + M} \right].$$  \tag{8}

There is also an additional contribution to the gauge boson self-energy coming from the adjoint Higgs field (diagram m):

$$\delta \Pi_{A_0}^{H} (p, m, M, m_D) = \frac{3cg v m}{2\pi M^2 m_D}.$$  \tag{9}

The contribution of $\tilde{A}_0$ to the Higgs self-energy (diagrams j-l) is the following

$$\delta \Pi_{H}^{\tilde{A}_0} (p, m, m_D) = - \frac{3m_D c v}{2\pi} - \frac{6c^2 v^2}{\pi} \frac{1}{p} \arctan \frac{p}{2m_D} + \frac{9g cv}{4\pi m} m_D.$$  \tag{10}

Making use also of the pieces of the self-energies calculated in \[12, 19\] we write down a set of coupled on-shell gap equations for the screening masses of the magnetic gauge bosons, fundamental
Higgs and adjoint $A_0$ fields in the form

\begin{align}
    m^2 &= \Pi_T(p = im, m, M) + \delta \Pi_T^{A_0}(p = im, m_D) + \delta \Pi_H^{A_0}(p = im, m, m_D), \quad (11) \\
    M^2 &= \Sigma(p = iM, m, M) + \delta \Pi_T^{A_0}(p = im, m, m_D), \quad (12) \\
    m_D^2 &= \Pi_{00}(p = iM, m, m_D) + \delta \Pi_{A_0}^{H,G,gh}(p = im_D, m, M, m_D), \quad (13)
\end{align}

where $\Pi_T$ and $\Sigma$ are defined by eqs. (17), (18) of Ref. [12]. $\delta \Pi_T^{A_0}$ and $\Pi_{00}$ were presented in eqs. (7), (8) of [13].

If on the right hand side of the third equation one inserts the tree level masses, the next-to-leading order result of Ref. [20] is recovered for the Debye mass in the $SU(2)$ Higgs model.

The equation for the vacuum expectation value makes the set of the above three equations complete:

\[ v(\mu^2 + \lambda v^2) = \frac{3}{16\pi} g \left( 4m^2 + \sqrt{\xi M^2 + \frac{M^3}{m}} \right) + \frac{3c}{2\pi} vm_D. \]  

(14)

It is important to notice that this equation can be rewritten as

\[ v(\mu_{eff}^2 + \lambda v^2) = \frac{3}{16\pi} g \left( 4m^2 + \sqrt{\xi M^2 + \frac{M^3}{m}} \right), \]  

(15)

with

\[ \mu_{eff}^2 = \mu^2 - \frac{3c}{2\pi} m_D. \]  

(16)

This equation is formally identical to the equation of BP for the vacuum expectation value [12].

On the basis of this observation, we expect that the main effect of the $A_0$ integration is the above shift in the $\mu^2$-scale. Since $m_D$ is itself a non-trivial function of $\mu$ this non-perturbative mapping is also nonlinear.

A very similar set of equations could be derived for the case of the gauge invariant resummation of the $A_0-\Phi$ vertex. They are listed in Appendix B. For instance, one would write in the last term on the right hand side of (14) $2m/g$ on the place of $v$, which would suggest a different redefinition of the temperature ($\mu^2$) scale:

\[ \tilde{\mu}_{eff}^2 = \mu^2 - \frac{3c}{\pi g} \frac{m m_D}{v}. \]  

(17)

If the tree level masses are inserted into this redefinition it gives the usual relation between the mass parameters of the full static and the $A_0$-reduced models (see Eq. (1)).

### 3 Numerical results

The main goal of the present investigation is to propose a scheme of solution for the full static Higgs model [1] which reproduces the BP solution of the reduced static model (with $A_0$ integrated out). The existence of such a solution is made plausible by the Appelquist-Carazzone theorem [21], but by no means it is trivial to construct it for two obvious reasons. The decoupling theorem is valid only for infinitely different mass scales, while the $m_D/m$, $m_D/M$ ratios are finite in the realistic case. There are corrections to the theorem even if we would be able to compare the exact values of the corresponding masses calculated in the two models for the perturbatively related values of the couplings. The second source of deviations comes from the resummation applied in the process of the perturbative solutions. It is not clear which resummed solution of the full static
model would correspond to the BP-resummed approximate solution of the reduced 3d effective model at one-loop level.

Though the construction of a good quality correspondence is a very difficult task, it is a necessary effort if one wishes to go beyond the "existence proof" of the decoupling in case of the resummed solutions.

We have to admit that it would be much easier to assess the status of $A_0$-decoupling and the quality of the BP-solution if the exact (Monte-Carlo) solution of the model (1) would be available. However, Monte-Carlo simulations of the gauge + fundamental + adjoint Higgs system are extremely difficult to realize (see discussion in Ref. [5]). Therefore our present construction can be considered a first detailed attempt to establish quantitative arguments for the $A_0$-decoupling.

Our first attempt at solving the full static model followed the gauge invariant vertex resummation procedure employed also by the BP solution of the $A_0$-reduced model. In Fig.1 the results of the two solutions for the Higgs mass $M$ are displayed taking into account the perturbative mapping (17) between the parameters of the two models. The deviations are large, especially in the critical region. We arrived at a negative conclusion: The gauge invariantly resummed one-loop solutions of the gap equations of the two models do not correspond to each other if the perturbative $A_0$-integration is correct.

We have also tried to compare the predictions of the full static and the reduced models in the case when the mass parameter of the reduced model is chosen according Eq. (17). Such non-perturbative mapping between the parameters of the two models improves somewhat the situation deep in the broken phase, however, near the crossover region the values of the masses calculated in the two models differs considerably. We conclude that if gauge invariant resummation of the $A_0 - \Phi$ vertex is used we are not able to find a physically motivated relation between the parameters of the full static and the reduced models with the help of which the two models give acceptably close mass predictions. Therefore we will not discuss further the fully gauge invariant resummation scheme but turn to the discussion of the results obtained in the case when the $A_0 - \Phi$ vertex left
Fig. 2: The Higgs boson masses at $\lambda/g^2 = 1/8$ (crossover region) in units of $g^2$ as function of $\mu^2/g^4$ in the 3d fundamental + adjoint Higgs model and in the 3d SU(2) Higgs ($A_0$-reduced) theory. Shown are the Higgs mass in the full static theory in the $\xi = 0$ (Landau) gauge (a) and in the $\xi = 1$ (Feynman) gauge (b), and the Higgs boson mass in the $A_0$-reduced theory in the $\xi = 0$ gauge (c) and in the $\xi = 1$ gauge (d).

If the $A_0 - \Phi$ vertex left unresummed, a very simple expectation emerges concerning the effect of the $A_0$ integration on the mass spectra, as it was discussed on the basis of (16) in the previous section. Therefore, we will first compare the predictions for the Higgs and gauge boson masses from the coupled gap equations (11)-(14) of the 3d fundamental + adjoint Higgs model with those obtained in the $A_0$-reduced theory, the 3d Higgs model [12]. The corresponding Higgs masses are shown in Fig. 2 using two different gauges. The results obtained in the $A_0$-reduced theory are displayed after the shift required by eq.(4) is performed. As one can see the difference between the full and the reduced theory is still visible in the vicinity of the crossover. In this region the relative difference between the predictions of the full and the reduced theory is about 20%.

Our proposal to resolve this relatively large deviation is to introduce a more complicated relationship between the couplings. Having gained intuition from eq.(16), we have plotted the mass-predictions for the Higgs-field derived from our full set of equations against the results of BP calculated for couplings taken from (4) with a replacement $\mu_D \to m_D$:

$$g_{\text{eff}}^2 = g^2(1 - \frac{g^2}{24\pi m_D}), \quad \lambda_{\text{eff}} = \lambda - \frac{3c^2}{2\pi m_D}, \quad \mu_{\text{eff}}^2 = \mu^2 - \frac{3c}{2\pi} m_D. \quad (18)$$

The non-trivial nature of this replacement becomes clear from Fig.3 where the $\mu^2$-dependence of $m_D$ is displayed. Clearly, its non-trivial $\mu^2$-dependence is most expressed in the neighbourhood of the phase transformation (crossover) point $\mu^2/g^4 \in (0.1-0.2)$. The application of this mapping to the data obtained from the model containing both the fundamental and the adjoint representation leads to a perfect agreement of the two data sets for large values of $\lambda/g^2$. For smaller values of $\lambda/g^2$ (1/32, 1/64) the mapping (18) works very well in the symmetric phase, but in the broken phase (4) seems to be the better choice.

We suspect, that the tree level piece in $m_D$ arising from the Higgs-effect, should not be included into the correction of (4), since it is itself a tree-level effect. Therefore we propose the following
replacement in (18):
\[ m_D \rightarrow \sqrt{m_D^2 - 2cv^2}. \]  \hspace{1cm} (19)

In Fig.4 it is obvious that a very good agreement could be obtained with this mapping between the Higgs mass predictions of the one-loop gap equations of the full static and the \( A_0 \)-reduced theory for \( \lambda/g^2 = 1/32 \). The quality of the agreement on both sides of the phase transition is good, signalling that the influence of the “mini-Higgs” effect in the symmetric phase is negligible. Therefore it is not surprising that for \( \lambda/g^2 = 1/8 \) the same quality of agreement is obtained like before.

It is important to notice that there is a strong gauge parameter dependence in the symmetric phase and in the vicinity of the crossover. The variations due to the change in the gauge are equal in the full and in the reduced theory, which indicates that the additional gauge dependence, introduced by the gauge non-invariant resummation of the \( A_0 \) field is negligible. The mapping (19) performs equally well in Landau- and Feynman-gauges.

Other quantities which are worth of considering for the comparison of the full 3d and the reduced theories are \( \lambda_c/g^2 \), the endpoint of the first order transition line and \( \mu^2_+/g^4 \), the mass parameter above which the broken phase is no longer metastable. The values of \( \mu^2_+/g^4 \) for different scalar couplings and different gauges in the full and in the reduced theory are summarized in Table 1. Here the mapping (18) could be implemented only by extrapolating from smaller \( \mu^2_+/g^4 \), since the end-points of metastability do not correspond to each other, and in some cases \( m_D \) could not be determined from the gap equations. Also here for larger values of \( \lambda/g^2 \) the application of (18) led to an improved agreement between the end-point \( \mu^2_+/g^4 \) values, while for \( \lambda/g^2 = 1/48, 1/64 \) the mapping (19) works better. In the table we have displayed \( \mu^2_+/g^4 \) values of the \( A_0 \)-reduced theory shifted perturbatively and with help of the best performing non-perturbative mapping (19). For both gauges the latter agrees with the \( \mu^2_+/g^4 \)-values of the full static theory very well.

| \( \lambda/g^2 \) | \( A \) | \( B \) | \( C \) |
|-----------------|--------|--------|--------|
|                 | \( \xi = 0 \) | \( \xi = 1 \) | \( \xi = 0 \) | \( \xi = 1 \) |
| 1/32            | 0.1516 | 0.1423 | 0.1426 | 0.1341 | 0.1499 | 0.1405 |
| 1/48            | 0.1647 | 0.1558 | 0.1627 | 0.1541 | 0.1637 | 0.1546 |
| 1/64            | 0.1841 | 0.1750 | 0.1881 | 0.1808 | 0.1875 | 0.1792 |

Table. 1: Values of \( \mu^2_+/g^4 \) in the full static theory (A), in the perturbatively reduced theory (B) and in the reduced theory obtained using non-perturbative matching described in the text (C). Calculations were done in the Landau (\( \xi = 0 \)) and in the Feynman (\( \xi = 1 \)) gauges.

The endpoint of the 1st order line in the Landau gauge in the 3d Higgs theory was found at \( \lambda_c/g^2 = 0.058 \). The corresponding critical scalar coupling in the full 3d theory is within the 1% range. In Feynman gauge we find \( \lambda_c/g^2 = 0.078 \) for the \( A_0 \)-reduced theory and the corresponding value for the full 3d theory lies again very close to it. Thus the \( A_0 \) field has almost no effect on the position of the endpoint. The strong gauge dependence of \( \lambda_c \) indicates, however, that higher order corrections to this quantity are important.

The gauge dependence of the screening masses is even more pronounced deep in the symmetric phase (\( \mu^2_+/g^4 > 0.3 \)). For example the value of the gauge boson mass is roughly 0.28\( g^2 \) in the symmetric phase for the Landau gauge. The corresponding value in the Feynman gauge is about 0.22\( g^2 \). The gauge dependence of the gauge boson mass is somewhat weaker at the 2-loop level [15]. It should be also noticed that the gauge boson mass depends weakly on the parameters of the scalar sector \( (\mu, \mu_D, \lambda, \lambda_A) \). This fact was also noticed in previous investigations [12, 14].
Fig. 3: The $\mu^2$ dependence of the Debye mass for $\frac{\lambda}{g^2} = 1/8$.

Fig. 4: The Higgs boson mass in units of $g^2$ as function of $\mu^2/g^4$ calculated at $\lambda/g^2 = 1/32$ in the Landau gauge in the full static theory and in the $A_0$-reduced theory. Shown are the Higgs mass in the reduced theory obtained by perturbative reduction (a), in the reduced theory obtained by non-perturbative matching (cf. eqs. (18), (19)) (b) and in full static theory (c).
4 Screening masses in the symmetric phase with a gauge invariant resummation scheme

The main motivation for the present investigation was to gain insight into the decoupling of the dynamics of the fundamental and the adjoint Higgs fields. The degree of the decoupling is expected to depend on the mass ratio of the fundamental and adjoint Higgs fields. In the symmetric phase both masses are of the same order in magnitude (e.g. \( gT \)). Therefore the hierarchy of the \( A_0 \) and Higgs masses can only be present due to numerical prefactors. The persistence of the perturbatively calculated ratio should be checked in any non-perturbative approach.

As we have seen in the previous section the gauge dependence in the symmetric phase is too strong in the applied schemes to give a stable estimate for the mass ratio of the fundamental and the adjoint Higgs fields. A reliable non-perturbative estimate for the Higgs mass deep in the symmetric phase (defined through the pole of the propagator) is even more interesting because it was not measured so far on lattice. Therefore, in this section we will investigate a coupled set of gap equations in the symmetric phase which is based on the gauge invariant resummation scheme of Alexanian and Nair (AN) \(^22\). In this approach one can avoid any vacuum expectation value for the Higgs field in the symmetric phase and because of this fact this approach is gauge invariant.

In order to derive the 1-loop gap equations for the Higgs model in the AN scheme one has to add the following terms to the original Lagrangian:

\[
\delta L = \frac{1}{2} m^2 A_i (\delta_{ij} + \frac{\partial_i \partial_j}{\partial^2}) A_j + f^{abc} V_{ijk} A_i^a A_j^b A_k^c - \frac{1}{2 \xi} \partial_i A_i (1 - m^2 \frac{1}{\partial^2}) \partial_j A_j. \tag{20}
\]

The first term in this expression is the mass term, the second corresponds to a specific vertex resummation, where the explicit expression for \( V_{ijk} \) could be find in Ref. \(^{22}\). Finally, the last term is the gauge fixing term. For the coupled gap equations one has to reevaluate those self-energy diagrams of the gauge, Higgs and \( A_0 \) fields which involve the modified gauge propagators from (20). Straightforward calculations lead to the following equations:
Fig. 6: The non-perturbative correction to the Higgs mass as the function of $\mu$ calculated from the full static (a) and from the $A_0$-reduced theory (b).
It is also important to notice that the $A_0$ field is not sensitive to the dynamics of the Higgs field. In particular it turns out that $m_D$ depends weakly on $\mu$ and $\lambda$ in the symmetric phase and its value is close to the corresponding value calculated in 3d adjoint Higgs model. Let us notice that the magnetic mass in this resummation scheme also seems to be insensitive to the dynamics of scalars, therefore the magnetic and electric screening masses are close to their values determined in the pure $SU(2)$ gauge model [19].

5 Conclusions

The Appelquist-Carazzone (AC) theorem provides an important asymptotic basis for the derivation of reduced effective models, when fields with largely different masses appear in a field theoretical model. It states that in the infinite mass limit the n-point functions of the light degrees of freedom can be calculated from an effective theory, in which the effect of the heavy fields is present only in the couplings. In the electroweak theory these effective models were determined perturbatively. In resummed perturbation theory for finite orders the fulfillment of the theorem cannot be checked on a diagram by diagram basis.

The comparative investigation of the screening masses of the full static and the $A_0$-reduced theories of the finite temperature $SU(2)$ Higgs model gives us a very valuable opportunity to study how well the AC theorem works under realistic mass ratios. In particular in the symmetric phase of the theory we have seen that a non-perturbative coupling relation (18) is necessary to map almost perfectly the masses determined in the $A_0$-reduced model onto those found from the gap equations of the complete static effective model. The $\lambda/g^2$ -range $(1/64-1/8)$ has covered the regime of strong first order transitions to values where only smooth crossover takes place. The correspondence between specific solution schemes, which is compatible with the AC theorem represents constructive evidence for the validity of the theorem.

The quality of the mapping did not depend on the gauge-choice, which however, strongly influences the actual values of the screening masses. Therefore, we have applied also a gauge-invariant resummation scheme in the symmetric phase. The results show larger $m_D/M$ ratio than perturbatively predicted, which makes the basis for the $A_0$ reduction more solid.

In the broken symmetry phase the non-perturbative mapping as given by (18) does not work. The attempt to separate the non-perturbative change of the Debye-mass from the result of the symmetry breaking led us to propose the mapping (19). It gave very satisfactory results for both the Higgs mass and the upper metastability edge $\mu+/g^2$ in the Higgs-mass range $\lambda/g^2 \in (1/32,1/8)$, when resummed one-loop solutions of different relevant models in specific schemes are calculated. We believe that our phenomenological observation opens the path towards a more refined physical understanding of the relationship of the couplings in the two models. This is necessary for the consolidation of the status of a non-perturbative $A_0$-decoupling from the static sector of the finite temperature Higgs theory.

Appendix A

Below we list graphically the additional diagrams contributing to the $A_0$ (a-i), Higgs boson (j-l) and the vector boson (m) self-energies and the vacuum expectation value (n).

Appendix B

The gap equations for the masses in the gauge invariant resummation scheme read:

$$m^2 = m_0^2 + mg^2 f_B(m/M) + \frac{g^2}{2\pi} \left( -\frac{m_D}{2} + \frac{4m_D^2 - m^2}{4m} \arctanh \frac{m}{2m_D} \right), \quad (24)$$

$$M^2 = M_0^2 + g^2 MF_B(m/M) - \frac{3}{2\pi} \left( \frac{4mc}{g} \right)^2 \frac{1}{M} \arctanh \frac{M}{2m_D} - \frac{3}{2\pi} cm_D, \quad (25)$$

$$m_D^2 = m_D^2 + \frac{g^2}{\pi} \left[ -\frac{m_D}{2} - \frac{m}{2} + \left( m_D - \frac{m^2}{4m_D} \right) \ln \frac{2m_D + m}{m} \right] - 8v(\mu^2 + \lambda v^2) \frac{mc}{gM^2} +$$

$$\frac{1}{\pi} cM(1 + 6\frac{m^3}{M^3}) + \frac{1}{\pi} \left( \frac{4mc}{g} \right)^2 \left[ \frac{3m_D}{2M^2} - \frac{1}{2m_D} \ln \frac{2m_D + M}{M} \right], \quad (26)$$

$$v(\mu^2 + \lambda v^2) = -M^2 \delta f_B(m/M) + \frac{3c}{\pi g} mm_D. \quad (27)$$

where the $\delta f_B(z) = f_B(z) - \bar{f}_B(z)$ and $\bar{f}_B(z), f_B(z), F_B(z)$ are defined by the eq. (24), (30) and (31). of [12]:

$$\bar{f}_B(z) = \frac{1}{\pi} \left[ \frac{63}{64} \ln 3 - \frac{1}{8} + \frac{1}{32z^3} - \frac{1}{32z^2} + \frac{1}{8z} \right]$$
\[ f_B(z) = \frac{1}{\pi} \left[ \frac{63}{64} \ln 3 - \frac{1}{8} + \frac{1}{32z^3} - \frac{1}{32z^2} - \frac{1}{16z} + \frac{3\sqrt{\xi}}{16} \ln(1 + 2z) \right], \tag{28} \]

\[ F_B(z) = \frac{1}{\pi} \left[ -\left( \frac{3}{32} + \frac{9}{64} \ln 3 \right) \frac{1}{z^2} + \frac{3}{16} \left( 1 - \frac{3}{2} \sqrt{\xi} \right) \frac{1}{z} - \frac{3}{8} \left( \frac{3}{8z^2} - \frac{3}{16} + \frac{3}{64z^2} \right) \ln \frac{2z + 1}{2z - 1} \right]. \tag{29} \]
