RADIATIVE CORRECTIONS
TO QUARK-QUARK-REGGEON VERTEX IN QCD*

Abstract

One loop corrections to the coupling of the reggeized gluon to quarks are calculated in QCD. Combining this result with the known corrections to the gluon-gluon-reggeon vertex, we check the self-consistency of the representation of the amplitudes with gluon quantum numbers and negative signature in the $t$-channel in terms of Regge pole contribution.

1. Introduction

Since a long time it has been found [1] that, in the leading logarithmic approximation (LLA) for the Regge region, the total cross section $\sigma_{tot}^{LLA}$ in the non-Abelian SU(N) gauge theories grows at large c.m.s. energies $\sqrt{s}$:

$$\sigma_{tot}^{LLA} \sim \frac{s^{\omega_0}}{\sqrt{\ln s}}, \quad (1)$$

where

$$\omega_0 = \frac{g^2}{\pi^2} N \ln 2. \quad (2)$$

Therefore the Froissart bound $\sigma_{tot} < c \ln^2 s$ is violated in the LLA. The reason for this is the violation of the $s$-channel unitarity constraints for scattering amplitudes in the LLA.

The behaviour (1) of the total cross section is determined by the position of the most right singularity in the complex momentum plane in the solution of the integral equation for $t$-channel partial waves with vacuum quantum numbers [1]. In order to find out the region in which the LLA can be applied, radiative corrections to the equation’s kernel must be calculated. The calculation of these corrections was started by L.N. Lipatov and one of the authors (V.F.) in ref. [2], where the calculation program was presented. The program makes a strong use of the gluon reggeization proven in LLA [1]. As a necessary step in this program one needs to calculate one loop corrections to the particle-particle-reggeon (PPR) vertices. Here, the reggeon is the reggeized gluon and its trajectory in the LLA is given by

$$j(t) = 1 + \omega(t),$$

$$\omega(t) = \frac{g^2 t}{16\pi^3} N \int \frac{d^2k}{k^2(q - k)^2}, \quad t = -\bar{q}^2. \quad (3)$$

The infrared divergence in the gluon trajectory (3) is cancelled by the divergences in real gluon emission, so that the integral equation for the $t$-channel partial waves with vacuum quantum numbers [1] is free of singularities. In order to remove the infrared divergences at intermediate steps we use the dimensional regularization of Feynman integrals:

$$\frac{d^2k}{(2\pi)^2} \to \frac{d^{2+\varepsilon}k}{(2\pi)^{2+\varepsilon}}, \quad \varepsilon = D - 4, \quad (4)$$
where \( D \) is the space-time dimension (\( D = 4 \) for the physical case).

Then we get

\[
\omega(t) = g^2 N \frac{2}{(4\pi)^{\frac{D}{2}}} (-t)^{\frac{D}{2} - 2} \frac{\Gamma\left(2 - \frac{D}{2}\right) \Gamma^2 \left(\frac{D}{2} - 1\right)}{\Gamma(D - 3)}.
\]  

(5)

In the case of pure gluodynamics one loop corrections to the gluon-gluon-reggeon (GGR), as well as to the reggeon-reggeon-gluon (RRG) vertices were calculated by L.N. Lipatov and one of the authors (V.F.) [3, 4].

In the case of real QCD there is a quark contribution to the vertices; the quark loop contribution to the GGR vertex was calculated in ref. [5]. Besides that, in the real QCD an extra (compared to the pure gluodynamics case) vertex appears: the quark-quark-reggeon (QQR) vertex. The existence of this vertex allows us to check the validity of the assumption that the high energy behaviour of amplitudes with gluon quantum numbers in the \( t \)-channel and negative signature is governed by the Regge pole contribution not only in the LLA, but beyond it as well. According to this assumption the amplitude \( A_{AB}' \) of a process \( A + B \to A' + B' \) takes the following factorized form:

\[
P^- \mathcal{A} = \Gamma_{A'A} S_t \left[ \left(\frac{s}{t}\right)^{\omega(t)} + \left(\frac{-s}{t}\right)^{\omega(t)} \right] \Gamma_{B'B}.
\]  

(6)

Here \( P^- \) is the projection operator into the octet colour state with negative signature, \( i \) is the colour index of the reggeized gluon with the trajectory \( j(t) = 1 + \omega(t) \), given by eq.(3) in the lowest order of the perturbation theory. For the PPR vertex \( \Gamma_{A'A} \) in the helicity basis we get in the lowest order

\[
\Gamma_{A'A} = g \langle A'|T^i|A \rangle \delta_{\lambda_A,\lambda_A'}.
\]  

(7)

where \( \langle A'|T^i|A \rangle \) represents the matrix element of the group generator in the corresponding representation (i.e. fundamental for quarks, \( T_i = t_i = \frac{1}{2} \) and adjoint for gluons, \( (T_i)_{ab} = -i f_{iab} \)) and \( \lambda_A \) is the helicity of particle \( A \). We assume that the polarization states of the scattered particles are obtained from those of the initial particles by rotation around the axis orthogonal to the scattering plane. From eq.(4) we may observe that the behaviour of the three types of amplitudes (gluon-gluon, quark-quark and quark-gluon elastic scattering amplitudes) is determined by two
vertices, GGR and QQR; therefore, one of the amplitudes can be expressed in terms of the others, thus giving a non trivial test of the validity of representation (6).

Contrary to eq.(7), in higher orders the PPR vertex $\Gamma$ can contain another spin structure. Due to parity conservation it can be written in the following form:

$$\Gamma^c_{A'A} = g \langle A'|\mathcal{T}|A \rangle \left[ \delta_{\lambda_A,\lambda_A'}(1 + \Gamma^{(+)\AA}) + \delta_{\lambda_A,-\lambda_A'}\Gamma^{(-)\AA} \right],$$ (8)

if relative phases of states with opposite helicity are chosen appropriately (see ref.s [4, 5] for gluons and eq.(36) below for quarks). Here $\Gamma^{(+)}$ and $\Gamma^{(-)}$ respectively stand for helicity conserving and non conserving loop contributions to the vertex.

One loop corrections to GGR vertex were calculated in ref.s [3-5]. The contribution of the gluon loop can be written in the form (8) with

$$\Gamma^{(+)}_{GG}(\text{gluon loop}) = N g^2 \left(\frac{D}{2} - 2\right) \left(\frac{1}{2} - \frac{D}{2}\right) \left(\frac{D}{2} - 1\right) \frac{\Gamma(2 - \frac{D}{2}) \Gamma^2 \left(\frac{D}{2} - 1\right)}{\Gamma(D - 2)}$$

and

$$\Gamma^{(-)}_{GG}(\text{gluon loop}) = N g^2 \left(\frac{D}{2} - 2\right) \left(\frac{1}{2} - \frac{D}{2}\right) \left(\frac{D}{2} - 1\right) \frac{\Gamma(2 - \frac{D}{2}) \Gamma^2 \left(\frac{D}{2} - 1\right)}{(D - 1) \Gamma(D - 2)},$$ (10)

where $\psi$ is the logarithmic derivative of the gamma function:

$$\psi(z) = \frac{\Gamma'(z)}{\Gamma(z)}.$$ (11)

For the quark loop contribution we have in turn [5]

$$\Gamma^{(+)}_{GG}(\text{quark loop}) = \frac{2 g^2}{(4\pi)^{\frac{D}{2}}} \sum_f V_+^{(f)},$$ (12)

where

$$V_+^{(f)} = -\Gamma \left(2 - \frac{D}{2}\right) \left[ \int_0^1 \frac{dx}{\left(m_f^2 - tx(1-x)\right)^{2-\frac{D}{2}}} + \int_0^1 \int_0^1 \frac{dx_1 dx_2 \theta(1-x_1-x_2)}{(m_f^2 - tx_1 x_2)^{2-\frac{D}{2}}} \left(\frac{3-D}{2}\right) (2 - x_1 - x_2) \right]$$

for $f = \text{quark}$. 

\[(2 - \frac{D}{2}) \frac{x_1 x_2 (1 - x_1 - x_2) t}{m_f^2 - t x_1 x_2} \right) \right], \quad (13)\]

and

\[V_{(f)} = \Gamma \left(3 - \frac{D}{2}\right) t \int_0^1 \int_0^1 dx_1 dx_2 \theta(1 - x_1 - x_2) x_1 x_2 (1 - x_1 - x_2) \left(\frac{m_f^2 - t x_1 x_2}{\sqrt{3 - \frac{D}{2}}} \right)^{3 - \frac{D}{2}} . \quad (14)\]

For massless quarks the two vertices become respectively

\[\Gamma_{GG}^{(+)}(\text{quark loop}) = \frac{2 g^2 n_f}{(4\pi)^\frac{D}{2}} (-t)^{\frac{D}{2} - 2} \frac{\Gamma \left(2 - \frac{D}{2}\right) \Gamma^2 \left(\frac{D}{2}\right)}{\Gamma(D)}, \quad (15)\]

\[\Gamma_{GG}^{(-)}(\text{quark loop}) = -\frac{2 g^2 n_f}{(4\pi)^\frac{D}{2}} (-t)^{\frac{D}{2} - 2} \frac{\Gamma \left(3 - \frac{D}{2}\right) \Gamma^2 \left(\frac{D}{2} - 1\right)}{\Gamma(D)}. \quad (16)\]

In this paper we calculate the QQR vertex in the one loop approximation and check the validity of describing amplitudes in terms of the Regge pole contribution, i.e. representation (6). In section 2 we find the QQR vertex by calculating the quark-quark scattering amplitude. Combining the result obtained with the one for the GGR vertex, eq.s (3)-(14), and Regge trajectory (5), we get with the help of eq.(6) a prediction for the quark-gluon scattering amplitude. In section 3 we perform an independent calculation of this amplitude and check the consistency of the approach comparing the result we arrive at with the predicted one. Some conclusions are illustrated in section 4.

2. Quark-Quark-Reggeon vertex

We will extract radiative corrections to the QQR vertex from the amplitude of quark-quark elastic scattering. The calculation can be carried out through usual methods starting from the Feynman diagrams for the quark-quark scattering. However, for our purposes it is more convenient to use the method based on the \(t\)-channel unitarity relation. This method was used in ref.s [3-5] to calculate analogous corrections to the GGR vertex. Here its application allows us to demonstrate the factorization property of scattering amplitudes in the most economic way.

From the \(t\)-channel unitarity point of view, it is natural to decompose an amplitude according to intermediate states in the \(t\)-channel. In one loop approximation we need to consider two particle intermediate state in the \(t\)-channel. We will
schematically represent in Fig. 1 the amplitude of the elastic scattering process
\( A(p_A) + B(p_B) \rightarrow A'(p_{A'}) + B'(p_{B'}) \) with two particle intermediate state in the
t-channel and will use the following notations:

\[
\begin{align*}
    s &= (p_A + p_B)^2, \quad u = (p_A - p_{B'})^2, \quad q = p_A - p_{A'} = p_{B'} - p_B = p_{C'} - p_C, \quad t = q^2, \\
    s_A &= (p_A + p_C)^2, \quad u_A = (p_A - p_{C'})^2, \quad s_B &= (p_B + p_{C'})^2, \quad u_B = (p_B - p_C)^2,
\end{align*}
\]

(17)

\( p_C \) and \( p_{C'} \) being the momenta of the two intermediate particles.

Instead of calculating the \( t \)-channel discontinuities using \( 2\pi \delta(p^2 - m^2) \) for inter-
mEDIATE particle line, we will calculate the contribution of diagram in Fig. 1 using
full Feynman propagators for intermediate particles [3, 5]:

\[
A_{AB}^{A'B'} = \sum_{CC'} \eta_{CC'} \int \frac{d^D p_C d^D p_{C'}}{(2\pi)^D i (p_C^2 - m_C^2 + i\varepsilon) (p_{C'}^2 - m_{C'}^2 + i\varepsilon)^2}.
\]

(18)

Here, the sum runs over kinds of intermediate particles, their polarization, colour
and flavour states. As already mentioned in the introduction, the space-time dimen-
sion \( D \) is not equal to 4, so that we can use the dimensional regularization for
removing both infrared and ultraviolet divergences [4]. The numerical coefficient
\( \eta_{CC'} \) depends on the kind of intermediate state in the \( t \)-channel, which can be a
gluon-gluon or quark-antiquark state: in the first case \( \eta_{GG} = \frac{1}{2} \) because of identity
of gluons, while in the second one \( \eta_{Q\bar{Q}} = -1 \) because of Fermi statistics. An arbi-
trary polynomial in \( t \) could be added to the result of integration in eq.(18), because
it does not change the \( t \)-channel discontinuity, but such terms would have a wrong
asymptotic behaviour incompatible with the renormalizability of the theory (cf.
[1, 4]). Nevertheless, for massive quarks, some uncertainty still remains. We can
add to the r.h.s. of eq.(18) terms with the pole structure in \( t \). In the case of pure
gluodynamics such terms were absent in our regularization scheme because of lack
of appropriate values with mass dimensions. Evidently, these terms are connected
with renormalization and will be considered at the end of this section.

2.1 Contribution of the quark-antiquark intermediate state

Let us first consider the simpler case of the quark-antiquark pair in the \( t \)- chan-
nel. In this case the amplitudes \( A_{AC}^{A'C'} \) and \( A_{BC}^{B'C'} \) in eq.(18) are the quark-quark
scattering amplitudes taken in Born approximation. For such amplitudes we get

\[
A_{AB}^{A'B'} = \langle A'|t^c|A\rangle \langle B'|t^c|B\rangle (\frac{g^2}{t}) \bar{u}(p_{A'}) \gamma^\mu u(p_A) \bar{u}(p_{B'}) \gamma_\mu u(p_B)
\]

5
where the second term contributes only for scattering of identical particles.

We are interested in the radiative correction to the QQR-vertex when the reggeon is a reggeized gluon, therefore one needs to project the amplitude \(19\) into the octet colour state. Firstly we use the completeness relation for the generators of the fundamental representation of \(SU(N)\):

\[
t_{\alpha\beta}t_{\gamma\delta} + \frac{1}{2N} \delta_{\alpha\delta} \delta_{\gamma\beta} = \frac{1}{2N} \delta_{\alpha\delta} \delta_{\beta\gamma},
\]

and obtain

\[
t_{\alpha\beta}t_{\gamma\delta} = -\frac{1}{N} t_{\alpha\beta}^c t_{\gamma\delta}^c + \frac{N^2-1}{2N^2} \delta_{\alpha\delta} \delta_{\beta\gamma}.
\]

Successively, introducing the definition

\[
P_{s} A_{AB}^{'A'B'} = \langle A'|T^c|A\rangle \langle B'|T^c|B\rangle \langle A_{s}\rangle_{AB}^{'A'B'}
\]

which will be used in the following, and using the result \(21\) we have

\[
(A_{s})_{AB}^{'A'B'} = \bar{u}(p_{A'})\gamma^\mu u(p_{A})\left(g^2\right)\bar{u}(p_{B'})\gamma^\mu u(p_{B})
\]

\[
+ \frac{\delta_{AB}}{N} \bar{u}(p_{B'})\gamma^\mu u(p_{A})\left(g^2\right)\bar{u}(p_{A'})\gamma^\mu u(p_{B}).
\]

In order to apply the dispersion approach, it is convenient \([1,5]\) to decompose the amplitudes \(A_{AC}^{'A'C'}\) and \(A_{BC}^{'B'C'}\) entering eq.\(18\) into the sum of two terms which are schematically shown in Fig. 2:

\[
A_{AC}^{'A'C'} = A_{AC}^{'A'C'}(as) + A_{AC}^{'A'C'}(na),
\]

and analogous expression for \(A_{BC}^{'B'C'}\). The first term in the r.h.s. of eq.\(24\) contains the asymptotic contribution for the Regge kinematics, \(s_A \sim -u_A \gg t\), while the nonasymptotic part contains the remaining amplitude terms. When performing the decomposition \(24\) in the r.h.s. of \(18\), we are left with four contributions to \(A_{AB}^{'A'B'}\), corresponding to the diagrams in Fig. 3. Only the first three of them are important, instead the contribution of diagram in Fig. 3(d) can be disregarded. In fact, the essential values of variables \(s_A\) and \(s_B\) are small \((s_A \sim s_B \sim t)\) for the contribution of this diagram. Consequently, only transverse (with respect to the
(\(p_A, p_B\)) plane) components of momenta \(p_C\) and \(p_C'\) can be taken in the propagators of intermediate particles, which means that integrals over \(s_A\) and \(s_B\) are factorized and can be evaluated by residues; as a result, the contribution of diagram in Fig. 3(d) is purely imaginary in the Regge region and corresponds to positive signature partial waves [4]. Here we are interested in the radiative corrections to the QQR for the reggeized gluons, i.e. for the case of negative signature, therefore only diagrams in Figs. 3(a, b, c) can contribute.

The asymptotic contributions take the following form:

\[
\left( A_8^{(as)} \right)^{A' C'}_{AC} = \frac{(2g^2)}{t} \bar{u}(p_{A'}) \frac{\gamma}{s} u(p_A) \bar{u}(p_{C'}) \gamma_A u(p_C) \tag{25}
\]

and

\[
\left( A_8^{(as)} \right)^{C' B}_{C'B'} = \frac{(2g^2)}{t} \bar{u}(p_{C'}) \gamma_B u(p_{C'}) \bar{u}(p_{B'}) \frac{\gamma}{s} u(p_B) . \tag{26}
\]

We always take a very large value for \(s\) (in contrast to \(s_A\) and \(s_B\), which are integration variables and can be small as well as large), therefore we have, in the helicity basis,

\[
\bar{u}(p_{A'}) \gamma_s u(p_A) = \delta_{\lambda_A, \lambda_{A'}} ,
\]

\[
\bar{u}(p_{B'}) \frac{\gamma}{s} u(p_B) = \delta_{\lambda_B, \lambda_{B'}} , \tag{27}
\]

where \(\lambda_A\) is the helicity of particle \(A\). It is assumed that the polarization states of the scattered particles are obtained from the ones of the initial particles by rotation around the axis orthogonal to the scattering plane. That implies

\[
\varphi' = \exp \left( i\vec{\nu} \cdot \vec{\sigma} \theta \right) \varphi , \quad \vec{\nu} = \frac{\vec{p}' \times \vec{p}}{|\vec{p}' \times \vec{p}|} , \tag{28}
\]

where \(\varphi\) and \(\varphi'\) are respectively the polarization wave functions for initial and scattered particles and \(\theta\) is the scattering angle.

Let us note that if we write the asymptotic contribution \(\left( A_8^{(as)} \right)^{A' C'}_{AC}\) (see eq.(25)) in the helicity basis for particles \(A\) and \(A'\) using the first of eq.s (27), we arrive at the same expression as for the process in which \(A\) and \(A'\) are gluons [3].

Taking into account asymptotic parts (25) and (26) and decomposition (24), from eq.(23) we obtain the following projections for the nonasymptotic parts into
the octet colour state:

\[(A_{8}^{(na)})_{AC}^{A'C'} = g^{2} \left[ \bar{u}(p_{A'}) \gamma^{\mu} u(p_{A}) \frac{g^{\mu\nu}}{t} \bar{u}(p_{C'}) \gamma_{\nu} u(p_{C}) \right.
\]
\[+ \frac{\delta_{AC}}{N} \bar{u}(p_{C'}) \gamma^{\mu} u(p_{A}) \frac{1}{u_{A}} \bar{u}(p_{A'}) \gamma_{\mu} u(p_{C}) \right], \tag{29}
\]

\[(A_{8}^{(na)})_{CB}^{C'B'} = g^{2} \left[ \bar{u}(p_{C}) \gamma^{\mu} u(p_{C'}) \frac{g^{\mu\nu}}{t} \bar{u}(p_{B'}) \gamma_{\nu} u(p_{B}) \right.
\[+ \frac{\delta_{CB}}{N} \bar{u}(p_{B'}) \gamma^{\mu} u(p_{C'}) \frac{1}{u_{B}} \bar{u}(p_{C}) \gamma_{\mu} u(p_{B}) \right], \tag{30}
\]

where the decomposition
\[g^{\mu\nu} \simeq g^{\mu\nu}_{\perp} + 2 \left( \frac{p_{A}^{\mu} p_{B}^{\nu} + p_{B}^{\mu} p_{A}^{\nu}}{s} \right) \tag{31}\]

has been used and \(\perp\) means transverse to the \((p_{A}, p_{B})\) plane. We neglect terms containing \(\bar{u}(p_{A'}) \gamma_{\mu} u(p_{A})\) or \(\bar{u}(p_{B'}) \gamma_{\mu} u(p_{B})\) because they are proportional to the corresponding masses and therefore cannot give a contribution of order \(s/t\) to amplitude \((18)\).

Inserting eq.s (25) and (26) into eq.(18) we get for the contribution of diagram in Fig. 3(a) (cf. eq.s (20)-(22) of [5])

\[(A_{8}^{(a)})_{AB}^{A'B'} = \delta_{\lambda_{A}, \lambda_{A'}} \delta_{\lambda_{B}, \lambda_{B'}} \left( \frac{2g^{2}}{t} \right)^{2} p_{A}^{\mu} p_{B}^{\nu} \sum_{f} p_{f}^{(f)}(q), \tag{32}\]

where summation is performed over quark flavours and

\[\mathcal{P}_{\mu\nu}^{(f)}(q) = \frac{i}{2} \int \frac{d^{D}p}{(2\pi)^{D}} \text{tr} \left[ \gamma^{\mu} (\mathbf{p} + t \mathbf{m}_{f}) \gamma^{\nu} (\mathbf{p} - t \mathbf{m}_{f}) \right] = \frac{4\Gamma \left( 2 - \frac{D}{2} \right)}{(4\pi)^{\frac{D}{2}}} \left( -g_{\mu\nu} q^{2} + q_{\mu} q_{\nu} \right) \int_{0}^{1} \frac{dx x (1 - x)}{\left( m_{f}^{2} - q^{2} x (1 - x) \right)^{2 - \frac{D}{2}}} \tag{33}\]

Here, the calculations practically coincide with those of ref. [5] because, as we previously noted, the asymptotic contribution \((A_{8}^{(as)})_{AC}^{A'C'}\) (and \((A_{8}^{(as)})_{BC}^{B'C'}\) as well) in the helicity basis for particles \(A\) and \(A'\) (correspondingly \(B\) and \(B'\)) coincides with that of the case considered in ref. [5], where particles \(A\) and \(A'\) (\(B\) and \(B'\)) are gluons.

8
The contribution of diagram in Fig. 3(b) is expressed by the product \( (A^{(as)})^{A'C'}_{AC} \times (A^{(na)})^{CB'}_{C'B} \). Using eqs. (25) and (30) and keeping only terms of order \( s \) we find
\[
\left( A_s^{(b)} \right)^{A'B'}_{AB} = \delta_{\lambda_A,\lambda_A'} \frac{\alpha^s p^\mu_A}{Nt} \bar{u}(p_B') \mathcal{V}_\mu(p_B',q)u(p_B),
\]
where
\[
\mathcal{V}_\mu(p_B',q) = i \int \frac{d^D p}{(2\pi)^D} \frac{\gamma^\nu(\not{p} + \not{q} + m_B)\gamma_\mu(\not{p} + m_B)\gamma_\nu}{(p^2 - m_B^2 + i\varepsilon)((p + q)^2 - m_B^2 + i\varepsilon)((p_B - p)^2 + i\varepsilon)}. \quad (35)
\]
The integrals appearing in eq. (35) are calculated in Appendix. Let us accept that, by definition, states with opposite helicity are connected by relation
\[
\varphi_{-\lambda} = \bar{\nu} \cdot \bar{\sigma} \varphi_\lambda, \quad \bar{\nu} = \frac{\not{p}' \times \not{p}}{|\not{p}' \times \not{p}|},
\]
which, in the helicity basis, leads to
\[
\bar{u}(p_{A'})u(p_A) = 2m_A\delta_{\lambda_A,\lambda_{A'}} - i\sqrt{-t}\delta_{\lambda_{A'},-\lambda_A}. \quad (37)
\]
With such a definition we obtain
\[
\frac{p^\mu_A}{s} \bar{u}(p_B') \mathcal{V}_\mu(p_B',q)u(p_B) =
\]
\[
\frac{\Gamma\left(3 - \frac{D}{2}\right)}{(4\pi)^{D/2}} \int_0^1 \frac{dx}{(m_B^2 - x(1 - x)t)^{\frac{D}{2}}} \left\{ \frac{2\delta_{\lambda_B,\lambda_{B'}}}{4 - D} \left[ \frac{t}{D - 3} \right] \left( 1 - \frac{D - 1}{D - 3}m_B^2 \right) - \frac{5 - D}{D - 3}m_B\sqrt{-t} \right\}. \quad (38)
\]
Let us pay attention to the fact that the contribution given by eqs. (34) and (37) does not depend on the nature of particle A.

Finally the contribution \( (A_s^{(c)})^{A'B'}_{AB} \) of the diagram in Fig. 3(c) can be obtained from eqs. (34) and (38) by the substitution \( A \leftrightarrow B \). Summing up the three contributions and comparing the sum \( A^{(a)} + A^{(b)} + A^{(c)} \) with the factorized form (3), where the vertices are defined through eq.(8), we find
\[
\Gamma^{(q\bar{q} \text{ state})}_{QQ} = \frac{g^2}{(4\pi)^{D/2}} \Gamma\left(2 - \frac{D}{2}\right) \left\{ -2 \sum_{f} \int_0^1 \frac{dx(1 - x)}{(m_f^2 - x(1 - x)t)^{2 - \frac{D}{2}}} \right\}
\]
\[
\Gamma^{(-)}(q\bar{q} \text{ state}) = \frac{-ig^2}{(4\pi)^{\frac{D}{2}}} \frac{\Gamma \left( 3 - \frac{D}{2} \right)}{2N} m_Q \sqrt{-t} \frac{(5 - D)}{(D - 3)} \int_0^1 \frac{dx}{(m_Q^2 - x(1-x)t)^{3-\frac{D}{2}}}. 
\]

(39)

We expect that for massless quarks only the helicity conserving part of the vertex survives and in fact in this case eq.s (39) and (40) reduce to

\[
\Gamma^{(+)}(q\bar{q} \text{ state})|_{m_q=0} = \frac{g^2}{(4\pi)^{\frac{D}{2}}} \left(-t\right)^{\frac{D}{2}-2} \left[-2\Gamma \left( 2 - \frac{D}{2} \right) \right. \\
\left. \text{with } n_f \frac{\Gamma^2 \left( \frac{D}{2} \right)}{\Gamma(D)} \right. \\
+ \frac{\Gamma \left( 3 - \frac{D}{2} \right)}{2N} \frac{\Gamma^2 \left( \frac{D}{2} - 1 \right)}{\Gamma(D - 2)} \left[ 2 + \frac{D}{2 \left( \frac{D}{2} - 2 \right)^2} \right] \quad , 
\]

(41)

\[
\Gamma^{(-)}(q\bar{q} \text{ state})|_{m_q=0} = 0 . 
\]

(42)

Here \( n_f \) is the number of quark flavours.

### 2.2. Contribution of the two gluon intermediate state

Now let us consider the contribution of two gluon intermediate state in the \( t \)-channel to the QQR vertex. The general lines of the consideration are the same as before, but now we need to take the quark-gluon scattering amplitude in Born approximation for the amplitudes \( A^{AC'}_{AC} \) and \( A^{CB'}_{C'B} \) in eq.(18). Again, as in the quark contribution case, we are interested only in parts of the amplitudes which correspond to the octet colour state in the \( t \)-channel, because our reggeon is the reggeized gluon. Moreover, we need to keep only the F-type colour octet for intermediate gluons, because only this colour state survives in the Regge asymptotic regime. Consequently the asymptotic contribution \( A^{(as)} \) in the decomposition (24) can contain only this colour state, which is, therefore, the only state that contributes to the essential diagrams in Fig.s 3(a, b, c).

This part of the quark-gluon scattering amplitude \( A^{AC'}_{AC} \) can be written as (cf. ref.[3])

\[
(A_8)^{AC'}_{AC} = \frac{(-g^2)}{2} \bar{u}(p_A') \left\{ \psi_C \left( \frac{\psi_A - \psi_{C'} + m_A}{u_A^2 - m_A^2} \right) \varphi_{C'} - \psi_{C'} ^* \left( \frac{\psi_A + \psi_{C'} + m_A}{s_A^2 - m_A^2} \right) \varphi_C \right\} 
\]
\[ + \frac{2}{t} \left[ (\mathbf{p}_C + \mathbf{p}_{C'}) e^{*}_{C'} \cdot \mathbf{e}_C + 2 \mathbf{q}_C (e^{*}_{C'} \cdot \mathbf{q}) - 2 \mathbf{q}^{*}_{C'} (e_C \cdot \mathbf{q}) \right] u(p_A) . \] (43)

In contrast with ref. [4], here gluons are intermediate particles, so that we do not fix their gauge. Instead we write the asymptotic parts of the amplitudes in a form similar to the one used in ref. [4] for the gluon-gluon scattering amplitude. The possibility of such a choice comes from the fact that the high energy behaviour of both amplitudes is determined by the \( t \)-channel exchange of a gluon which reggeizes. In the helicity basis (see eq.(27)) we have

\[
\left( A_8^{(as)} \right)^{A'C'}_{AC} = g^2 \delta_{\lambda_A, \lambda_{A'}} e^{*}_{C'} e^{*}_C \Gamma_{\sigma\sigma'} (p_C, p_{C'}, p_A) ,
\]

(44)

\[
\left( A_8^{(as)} \right)^{C'B'}_{C'B} = g^2 \delta_{\lambda_B, \lambda_{B'}} e^{*}_C e^{*}_{C'} \Gamma_{\sigma'\sigma} (p_{C'}, p_C, p_B) ,
\]

(45)

with

\[
\Gamma_{\sigma\sigma'} (p_C, p_{C'}, p_A) = -g^2 \sigma' \left( s_A - u_A \right) - 2 \left( \frac{2}{t} + \frac{1}{s_A - m_A^2} \right) p^2_A q^{\sigma'} + 2 \left( \frac{1}{s_A - m_A^2} - \frac{1}{u_A - m_B^2} \right) p^2_A \tilde{p}^{\sigma'}_{A'}
\]

(46)

and

\[
q = p_{C'} - p_C , \quad s_A = (p_A + p_C)^2 , \quad u_A = (p_A - p_{C'})^2 .
\]

(47)

It is worth to note that the tensor \( \Gamma_{\sigma\sigma'} \) can be considered as the generalization of the corresponding tensor used in ref. [4], for the gluon-gluon scattering amplitude, to the case for which \( p_A^2 = p_{A'}^2 = m_A^2 \neq 0 \).

In correspondence to the form we choose for the asymptotic term, the nonasymptotic contribution \( A^{(na)} \), taking into account eq.(27), becomes

\[
\left( A_8^{(na)} \right)^{A'C'}_{AC} = \left( -\frac{g^2}{2} \right) e^{*}_{C'} e^{*}_C \bar{u}(p_{A'}) \chi_{\sigma\sigma'} (p_C, p_{C'}, p_A, p_B) u(p_A) ,
\]

(48)

\[
\left( A_8^{(na)} \right)^{C'B'}_{C'B} = \left( -\frac{g^2}{2} \right) e^{*}_C e^{*}_{C'} \bar{u}(p_{B'}) \chi_{\sigma'\sigma} (p_{C'}, p_C, p_B, p_A) u(p_B) ,
\]

(49)

where

\[
\chi_{\sigma'\sigma} (p_C, p_{C'}, p_A, p_B) = \left( \gamma^0 - \frac{2 \mathbf{q}^0_{B'A}}{s} \right) \left[ 2 g^{\sigma\sigma'} (p_C + p_{C'})^0 \frac{t}{s} + 2 g^0 e \left( \frac{2 q^{\sigma'}}{t} - \frac{(p_A - q)^{\sigma'}}{s - m_A^2} \right) \right]
\]

(50)
Let us pay attention that the tensor $\Gamma_{\sigma\sigma'}(p_C, p_C', p_A)$ has the following properties on the mass-shell $p^2_C = p^2_{C'} = 0$:

$$\Gamma_{\sigma\sigma'}(p_C, p_C', p_A) p^\sigma_C = \Gamma_{\sigma\sigma'}(p_C, p_C', p_A) p^\sigma_{C'} = 0.$$  \hfill (51)

Consequently we can use the Feynman summation over polarization states of intermediate gluons:

$$\sum_\lambda \epsilon^{(\lambda)}_\mu \epsilon^{*(\lambda)}_\nu = -g_{\mu\nu},$$  \hfill (52)

when we calculate the contributions of the diagrams in Figs. 3(a, b, c), without introducing the Faddeev-Popov ghosts.

In the case of the diagram in Fig. 3(a) we need to calculate the product of the asymptotic parts (44) and (45). The essential region of integration in eq.(18) for large $s$ and fixed $t$ in this case is determined by relations

$$p^2_C \sim p^2_{C'} \sim s A s \sim t; \quad t \lesssim s_A \sim u_A \lesssim s; \quad t \lesssim s_B \sim u_B \lesssim s.$$  \hfill (53)

In this region from eq.(16) we find

$$\Gamma_{\sigma\sigma'}(p_C, p_C', p_A) \Gamma_{\sigma'\sigma}(p_C', p_C, p_B) = \frac{(D-4)}{t^2} \left( u_A - s_A \right) \left( u_B - s_B \right)$$

$$+ \frac{4}{t^2} \left( s_A s_B + u_A u_B \right) + \frac{16 s}{t^2} + s^2 \left( \frac{1}{s_A - m^2_A} - \frac{1}{u_A - m^2_A} \right) + \frac{1}{s_B - m^2_B} - \frac{1}{u_B - m^2_B}$$

$$+ 4 s \left( \frac{1}{s_A - m^2_A} + \frac{1}{s_B - m^2_B} \right) + \frac{1}{u_A - m^2_A} + \frac{1}{u_B - m^2_B} - 2 \left( \frac{u_B - m^2_B}{s_A - m^2_A} + \frac{s_B - m^2_B}{u_A - m^2_A} \right)$$

$$\times \left( 1 - \frac{2m^2_A}{t} \right) - 2 \left( \frac{u_A - m^2_A}{s_B - m^2_B} + \frac{s_A - m^2_A}{u_B - m^2_B} \right) \left( 1 - \frac{2m^2_B}{t} \right).$$  \hfill (54)

As to be expected, this expression differs from the corresponding one of ref. [4] only by mass terms, as well as $\Gamma_{\alpha\beta}$ does.

The integrals appearing in eq.(18), after substitution of eqs (44), (45) and (54), are presented in Appendix. By means of these integrals one can give the contribution of the diagram in Fig. 3(a) the following form:

$$\left( A^{(a)}_B \right)_{AB}^{A'B'} = \frac{N g^4}{(4\pi)^2} \delta_{\lambda_A, \lambda'_A} \delta_{\lambda_B, \lambda'_B} \frac{2s}{t} \left[ a(s, t) + \Delta a(m^2_A, t) + \Delta a(m^2_B, t) \right].$$  \hfill (55)
Here $a(t)$ is the contribution for the massless case (it is the same as in ref.[4]):

$$a(t) = \frac{\Gamma \left(2 - \frac{D}{2}\right) \Gamma^2 \left(\frac{D}{2} - 1\right)}{(-t)^{D-4} \Gamma(D-2)} \left\{ (D-3) \left[ \ln \left(\frac{-s}{-t}\right) + \ln \left(\frac{-u}{-t}\right) \right] 
+ 2\psi \left(3 - \frac{D}{2}\right) - 4\psi \left(\frac{D}{2} - 2\right) + 2\psi(1) \right\} + \frac{1}{2(D-1)} - \frac{4}{D-4} - \frac{9}{2} \right\}, \quad (56)$$

where $\psi(z)$ is defined in eq.(11), while $\Delta a(m^2, t)$ is mass dependent and becomes zero at $m = 0$:

$$\Delta a(m^2, t) = \Gamma \left(3 - \frac{D}{2}\right) \int_0^1 \int_0^1 dx_1 dx_2 \theta(1 - x_1 - x_2)$$

$$\int \frac{t (1 - x_1)^2}{x_1} \left[ \frac{1}{(x_1^2 m^2 - x_2 (1 - x_1 - x_2) t)^{\frac{D-4}{2}}} - \frac{1}{((-t) (1 - x_1 - x_2))^{\frac{D-4}{2}}} \right]$$

$$- \frac{2m^2 x_1}{(x_1^2 m^2 - x_2 (1 - x_1 - x_2) t)^{\frac{D-4}{2}}} \right]. \quad (57)$$

The essential point in eq.(50) is the separation of dependences on $m_A$ and $m_B$. Such separation is a vital necessity for the interpretation of the amplitude in terms of the Regge pole contribution (see eq.(3)).

Let us evaluate the contribution of the diagram in Fig. 3(b). It is expressed in terms of the integral (18), where we need to use the amplitudes (44) and (49). The essential region of integration in eq.(18) for this case is

$$p_C^2 \sim p_{C'}^2, s_B \sim u_B \sim t, \quad s_A \sim u_A \sim s. \quad (58)$$

In this region from (16) and (50) we obtain

$$\Gamma^{\sigma\sigma'}(p_C, p_{C'}, p_A) \bar{u}(p_B') \chi_{\sigma'}(p_C, p_{C'}, p_{B'}, p_{A'}) u(p_B) =$$

$$\bar{u}(p_B') \left\{ \frac{s_A - u_A}{t} \left[ \frac{2}{s_B - m_B^2} \left( m_B - (2m_B^2 - t) \frac{p_A}{s} \right) 
- \frac{2}{u_B - m_B^2} \left( m_B - (2m_B^2 - t) \frac{p_A}{s} \right) \right] 
- (D-2) \left[ \frac{\psi_{C'}}{u_B - m_B^2} + \frac{\psi_C}{s_B - m_B^2} \right] \right\} +$$

$$\frac{4}{t} \left[ \frac{d\psi_{C'} - \psi_A \psi_{C'} d}{u_B - m_B^2} + \frac{\psi_A \psi_C - d\psi_{C} \psi_A}{s_B - m_B^2} \right] \right\}. \quad (59)$$
An important property of this expression is its independence on \( m_A \). Remembering that the tensors \( \Gamma^{\sigma\sigma'}(p_C, p_{C'}, p_A) \) for the cases when the particles \( A \) and \( A' \) are gluons or quarks differ only by mass terms, we conclude that the contribution of diagram in Fig. 3(b) does not depend on the nature of particles \( A, A' \) if it is written in the helicity state basis for these particles. With the help of the Appendix, where integrals appearing in eq.(18) after substituting eqs. (44), (49) and (59) are calculated, and using the relation

\[
\bar{u}(p_B') \left( \gamma_B \gamma_A - \gamma_A \gamma_B \right) u(p_B) = \bar{u}(p_B') \left[ (t - 4m_B^2) \gamma_A + 2sm_B \right] u(p_B),
\]

which is a result of a simple algebra, we obtain for this contribution

\[
(A^{(b)})^{B'B}_{AA'} = \delta_{\lambda_A,\lambda_{A'}} \frac{g^4N}{t} (4\pi)^{D/2} \bar{u}(p_B') \int_0^1 \int_0^1 \frac{dx_1dx_2\theta(1-x_1-x_2)}{(x_1^2m_B^2 - x_2(1-x_1-x_2)t)^{3-D/2}} \left[ \frac{\gamma_A}{s} \left( -2m_B^2x_1 - \frac{D - 2}{D - 4} \left( m_B^2x_1^2 - x_2(1-x_1-x_2)t \right) \right) 
+ m_B \left( x_1 - \left( \frac{D}{2} - 1 \right)x_1^2 \right) \right] u(p_B).
\]

The contribution of the diagram in Fig. 3(c) can be obtained from eq.(61) by the substitution \( A \leftrightarrow B, A' \leftrightarrow B' \). The total contribution of the two gluon intermediate state in the \( t \)-channel to the asymptotic of the quark-quark scattering amplitude with the octet color state and negative signature in the \( t \)-channel is given by the sum \( A^{(a)} + A^{(b)} + A^{(c)} \). Comparing it with representation (8) we are once more convinced that Regge trajectory \( \omega \) in the lowest order is given by eq.(5) and find the two gluon intermediate state contribution to the quark-quark-reggeon vertex.

For the helicity conserving part of this contribution (see eq.(8)), performing the decomposition

\[
\Gamma^{(+)}_{QQ} = \Gamma^{(+)}_{QQ} |_{m_Q=0} + \Delta \Gamma^{(+)}_{QQ},
\]

with the help of eqs. (27) and (37) we obtain

\[
\Gamma^{(+)}_{QQ}(gg \text{ state}) |_{m_Q=0} = \frac{g^2N}{(4\pi)^{2}} \frac{\Gamma\left(2 - \frac{D}{2}\right)\Gamma\left(\frac{D}{2} - 1\right)}{(-t)^{D/2} \Gamma(D - 2)} \left[ (D - 3) \left( \psi\left(3 - \frac{D}{2}\right) 
- 2\psi\left(\frac{D}{2} - 2\right) + \psi(1) \right) + \frac{1}{4(D - 1)} - \frac{2}{D - 4} - \frac{7}{4} \right],
\]

14
and
\[ \Delta \Gamma^{(+)}_{QQ} (gg \text{ state}) = \frac{g^2 N}{(4\pi)^{\frac{D}{2}}} \Gamma \left( \frac{3 - D}{2} \right) \int_0^1 \int_0^1 dx_1 dx_2 \theta (1 - x_1 - x_2) \]
\[ \times \left[ - \frac{1}{(-x_2 (1 - x_1 - x_2) t)^{\frac{3 - D}{2}}} - m_Q^2 \left( \frac{2x_1 + (D - 2)(D - 3)x_2^2}{x_1^2 m_Q^2 - x_2 (1 - x_1 - x_2) t} \right)^{\frac{3 - D}{2}} \right]. \] (64)

For the helicity non-conserving part we have
\[ \Gamma^{(-)}_{QQ} (gg \text{ state}) = -i \frac{g^2 N}{(4\pi)^{\frac{D}{2}}} \Gamma \left( \frac{3 - D}{2} \right) m_Q \sqrt{-t} \]
\[ \times \int_0^1 \int_0^1 \frac{dx_1 dx_2 \theta (1 - x_1 - x_2)}{\left( x_1^2 m_Q^2 - x_2 (1 - x_1 - x_2) t \right)^{\frac{3 - D}{2}}} \left( x_1 - \left( \frac{D}{2} - 1 \right) x_1^2 \right). \] (65)

It vanishes in the zero mass limit, as it should do.

2.3. Renormalization of the QQR vertex

It was explained at the beginning of this section that we can add a term with
the pole structure in \( t \) to the r.h.s. of eq.(18) without changing the \( t \)-channel discontinuity and without spoiling the renormalizability of the theory. That means
we can add an expression which is equal to the Born amplitude with some constant coefficient. In principle, we could put on the helicity conserving part of the QQR vertex some condition (of the type of \( \Gamma^{(+)}_{QQ} |_{t=\mu^2=0} = 0 \) which would be a definition of the renormalized coupling constant. But it is useful to have a possibility to express
the QQR vertex in terms of the coupling constant in commonly used renormalization schemes, such as the \( \overline{MS} \) scheme. In order to have such a possibility we need to
connect our results to those which are obtained by the usual approach, in terms
of Feynman diagrams. In the diagrammatic approach the terms under discussion
may come from quark-gluon vertices and gluon polarization operator at \( t = 0 \) and
from self-energy insertions into external quark legs. It is easy to observe that the

15
first two contributions in Feynman gauge are taken into account properly in eq.s (32), (34) and (55), (61). So, we need only to consider the self-energy insertions into external quark legs. It means, that in the one loop approximation we need to add to the helicity conserving part of the QQR vertex the value
\[
\Gamma_{QQ}^{(+)}(self-energy) = -\frac{\partial \Sigma(p)}{\partial p} \bigg|_{p=m_Q},
\]
where \(\Sigma(p)\) is the mass operator of the quark:
\[
\Sigma(p) = -g^2 \frac{(N^2 - 1)}{2N} \int \frac{d^D k}{(2\pi)^D i} \frac{\gamma^\mu (p-k+m_Q) \gamma_\mu}{((p-k)^2 - m_Q^2 + i\varepsilon)}. \tag{67}
\]
An elementary calculation gives
\[
\Gamma_{QQ}^{(+)}(self-energy) = g^2 \frac{(N^2 - 1)}{2N} \frac{\Gamma(2 - \frac{D}{2})}{(4\pi)^{\frac{D}{2}}} m_Q^{D-4} \left(\frac{1 - D}{D - 3}\right). \tag{68}
\]

The total one loop correction to the helicity conserving part of the QQR vertex is given by the sum
\[
\Gamma_{QQ}^{(+)} = \Gamma_{QQ}^{(+)}(q\bar{q} \text{ state}) + \Gamma_{QQ}^{(+)}(gg \text{ state}) + \Gamma_{QQ}^{(+)}(self-energy),
\]
where the first term in the r.h.s. is given by eq.(39), the second by eq.(62) and the third by eq.(68). For the helicity non conserving part we have only contributions of the first two types, which are given by eq.s (40) and (65) correspondingly.

In all the above formulas we used the nonrenormalized coupling constant \(g\). Therefore expression (69) for \(D \to 4\) contains singularities coming from ultraviolet as well as infrared divergences of Feynman integrals. Let us note here that the helicity non conserving part of the vertex does not contain the ultraviolet divergences.

We can remove the ultraviolet divergences expressing \(g\) in terms of the renormalized coupling constant, for example, in the \(\overline{MS}\) scheme:
\[
g = g_{\mu} \mu^{-\frac{D-4}{2}} \left\{ 1 + \left(\frac{11}{3} N - \frac{2}{3} n_f\right) \frac{g^2}{(4\pi)^{\frac{D}{2}}} \left[ 1 + \frac{D-4}{2} \left(\ln \frac{1}{4\pi} - \psi(1)\right)\right] + \cdots \right\}, \tag{70}
\]
\footnote{One can wonder why Feynman gauge did appear here, while we used gauge invariant amplitudes and were talking about calculations without introducing the Faddev-Popov ghosts. The matter is, the gauge invariance used (see for example eq.(61)) is held on the mass shell only and has no relation to the terms under consideration.}
where $g_\mu$ is the renormalized coupling constant at the normalization point $\mu$ and $\psi(z)$ has been already defined (see eq.(11)).

3. Check of the approach consistency

Now we have both the gluon-gluon-reggeon vertex $\Gamma_{GG}^R$ and quark-quark-reggeon vertex $\Gamma_{QQ}^R$ in the one loop approximation. The first of them was calculated by using the gluon-gluon scattering amplitude as a tool, and the second via the quark-quark scattering amplitude. The process of quark-gluon scattering has not been considered up to now. But the reggeon contribution to this amplitude (see eq.(6)) is expressed in terms of the $GGR$ vertices and $QQR$ vertices and the gluon trajectory $1 + \omega(t)$, which is given in the one loop approximation by the formula (5). It allows us to check the validity of representation (6) for the high energy behavior of the amplitudes with gluon quantum numbers in the $t$-channel and negative signature.

It can be done by calculating the quark-gluon scattering amplitude and comparing the results of calculation with the expression given by formula (6) in terms of known trajectory $1 + \omega(t)$ and vertices $\Gamma_{QQ}^R$ and $\Gamma_{GG}^R$. But really we need not to perform any new calculation. The method of calculations used for gluon-gluon and quark-quark scattering amplitudes allows us to check the validity of the expression (6) simply by keeping an eye on the calculations we performed. Our starting point in calculating any amplitude is eq.(18). In each case we have two gluon and quark-antiquark intermediate states in the $t$-channel. An essential step in the calculation is the decomposition of the amplitude entering in the integrand of eq.(18) into the sum (24) (see Fig. 2) of asymptotic and non-asymptotic parts. An important fact is that a product of non-asymptotic parts in the integrand in eq.(18) cannot give a contribution of order $s$ to an amplitude with gluon quantum numbers in the $t$-channel and negative signature which we are interested in, so we are left with contributions presented schematically in Fig. 3(a, b, c).

The next important fact is that the asymptotic parts of the amplitudes $\left(A_s^{(as)}\right)_{AC}^{A'C'}$ and $\left(A_s^{(as)}\right)_{BC'}^{B'C'}$ can be chosen in a factorized form. Of course, this fact is strictly related to the case in which the high energy behaviour of the amplitudes is determined by gluon exchange in the $t$-channel. We choose the asymptotic parts for the case of quark-antiquark intermediate state $(CC')$ in the $t$-channel in the following
form:
\[
\left( A^{(as)}_s \right)_{AC}^{A'C'} = \frac{2g^2}{t} \delta_{\lambda_A \lambda_{A'}} \bar{u} (p_{C'}) \not{p}_A \not{u} (p_C) \tag{71}
\]
in the helicity basis for particles \( A \) and \( A' \), independently of what they are: gluons (see eq.s (17), (13) of Ref.[5]) or quarks (see eq.s (25) and (27) of this paper). Therefore, in this intermediate channel the contribution of the diagram in Fig. 3(a) does not depend on the kind of particles \( A, A' \) and \( B, B' \) (see eq.(32)). For the same reason the contribution of the diagram in Fig. 3(b) (Fig. 3(c)) depends only on the kind of the particles \( B, B' \) (\( A, A' \)). Taking into account that these diagrams contribute only to the vertices \( \Gamma_{BB'}^{R} \) and \( \Gamma_{AA'}^{R} \) correspondingly, we conclude that the contribution of the quark-antiquark intermediate state in the \( t \)-channel to an amplitude of any of the processes under consideration can be put in the form of eq.(3), where the vertices \( \Gamma_{AA'}^{R} \) (\( \Gamma_{BB'}^{R} \)) do not depend on the kind of particles \( B, B' \) (\( A, A' \)).

For the case of the two gluon intermediate state the conclusion is the same, although the properties of the asymptotic contributions are slightly changed. We choose these contributions in the form of eq.s (44)-(46) and here the dependence on the kind of the particles \( A, A' \) (\( B, B' \)) enters through the masses of these particles\(^2\). Of course in the Regge asymptotic limit for the amplitude \( A_{AC}^{AC'} (A_{BC}^{BP'}) \), that means for \( s_A \sim u_A \gg t \) (\( s_B \sim u_B \gg t \)), this dependence becomes negligible, but we need to integrate over \( s_A \) (\( u_A \)) in eq. (18). Therefore we choose these asymptotic contributions in such a form, which conserve the analytic properties of the exact amplitudes.

An essential property of asymptotic parts (44) and (45) is that the contribution of the diagram in Fig. 3(a), being calculated in terms of these parts, is presented in the form of eq.(55), where the dependences on the masses \( m_A \) and \( m_B \) are separated. Therefore, all the dependence on the kind of particles \( A, A' \) (\( B, B' \)) coming from this contribution is included into the vertices \( \Gamma_{AA'}^{R} \) (\( \Gamma_{BB'}^{R} \)). The same is true for the case of the contributions of the diagrams in Fig. 3(b, c) as well, because the contribution of the diagram in Fig. 3(b) (Fig. 3(c)) depends only on the kind of particles \( B, B' \) (\( A, A' \)) (see eq.(61)), just as in the case of the quark-antiquark intermediate state. Consequently we come to the same conclusion as for this case. Since the contributions of the quark-antiquark and two gluons intermediate states

\(^2\)Let us note, that, on the contrary, the dependence on \( p_A^2 = m_A^2 \) is negligible in eq.(63)
enter into the $PPR$-vertices additively, it means that the high energy behaviour of all QCD elastic scattering amplitudes with gluon quantum numbers in the $t$-channel and negative signature are presented by the Regge pole contribution (6).

4. Conclusions
We calculated one loop corrections to the quark-quark-reggeon vertex in the QCD, where the reggeon is a reggeized gluon. Taking into account this vertex together with the gluon-gluon-reggeon vertex calculated before, we get Regge pole contributions to gluon and quark elastic scattering processes. Since non-logarithmic terms of these contributions to the amplitudes of the three processes (gluon-gluon, quark-quark and quark-gluon elastic scattering) are expressed in terms of the two vertices, these amplitudes have to satisfy non trivial relations if the Regge pole only contributes to large $s$ behaviour of the amplitudes with gluon quantum numbers and negative signature in the $t$-channel. We have checked that these relations are fulfilled, i.e. the representation (6) of these amplitudes in terms of the Regge pole contribution is applicable beyond the leading logarithmic approximation (LLA) for the Regge region. The results obtained are needed for the next step in the calculation program [2] for corrections to the LLA: calculation of two loop corrections to the gluon Regge trajectory. In the two loop approximation a part of corrections to the trajectory comes from two particle intermediate states in the two channels. The calculation of this part can be performed by using the presented results. It will be done in a subsequent publication.

Appendix

For the reader’s convenience, here we are presenting the Feynman integrals appearing in eq.(18).

Let us first consider the case of quark-antiquark intermediate state. Calculating the contribution of the diagram in Fig.3(a) we meet the followings integrals:

$$I_{Q2} = -i \int \frac{d^D p}{(p^2 - m^2 + i\varepsilon) \left( (p + q)^2 - m^2 + i\varepsilon \right)} =$$
\[ \pi \frac{D}{2} \Gamma \left( 2 - \frac{D}{2} \right) \int_{0}^{1} \frac{dx}{(m^2 - x(1-x)t)^{\frac{D}{2} - 1}} , \]  

(A.1) 

\[ I_{Q2}^\mu = -i \int \frac{d^D p (-p^\mu)}{(p^2 - m^2 + i\varepsilon)((p + q)^2 - m^2 + i\varepsilon)} = \frac{q^\mu}{2} I_{Q2} , \]  

(A.2) 

\[ I_{Q2}^{\mu\nu} = -i \int \frac{d^D p p^\mu p^\nu}{(p^2 - m^2 + i\varepsilon)((p + q)^2 - m^2 + i\varepsilon)} = \pi \frac{D}{2} \Gamma \left( 2 - \frac{D}{2} \right) \int_{0}^{1} \frac{dx}{(m^2 - x(1-x)t)^{\frac{D}{2} - 1}} \left[ q^\mu q^\nu x^2 - \frac{g^{\mu\nu}(m^2 - x(1-x)t)}{2 - D} \right] . \]  

(A.3) 

Here and below \( q = p_A - p_A' = p_B' - p_B \), \( t = q^2 \).

For massless quarks the integrals (A.1)-(A.3) become the corresponding integrals presented in [4]:

\[ I_{Q2}|_{m=0} = I_2 = \pi \frac{D}{2} (-t)^{\frac{D}{2} - 2} \frac{\Gamma \left( 2 - \frac{D}{2} \right) \Gamma^2 \left( \frac{D}{2} - 1 \right)}{\Gamma(D - 2)} , \]  

(A.4) 

\[ I_{Q2}^\mu|_{m=0} = I_2^\mu = \frac{q^\mu}{2} I_2 , \]  

(A.5) 

\[ I_{Q2}^{\mu\nu}|_{m=0} = I_2^{\mu\nu} = [-g^{\mu\nu}t + q^\mu q^\nu D] \frac{I_2}{4(D - 1)} . \]  

(A.6) 

To obtain the contribution of the diagram in Fig.3(b) we need the following integrals:

\[ I_{Q3B} = -i \int \frac{d^D p}{(p^2 - m^2 + i\varepsilon)((p + q)^2 - m^2 + i\varepsilon)((p_B - p) + i\varepsilon)} = \pi \frac{D}{2} \Gamma \left( 3 - \frac{D}{2} \right) \int_{0}^{1} \int_{0}^{1} \frac{d\rho_2}{R_{Q3}^{\frac{3-D}{2}}} , \]  

(A.7) 

where

\[ d\rho_2 = dx_1 dx_2 \theta(1 - x_1 - x_2) , \]

\[ R_{Q3} = m^2(x_1 + x_2)^2 - x_1 x_2 t . \]  

(A.8) 

Making the substitution

\[ x_1 = u(1 - x) , \quad x_2 = ux \]
we easily perform the integration over $u$ arriving to

$$I_{Q3B} = \frac{\pi^{2}}{2} \frac{\Gamma \left( \frac{2-D}{2} \right)}{2} \int_{0}^{1} \frac{dx}{(m^2 - x(1-x)t)^{3-\frac{D}{2}}}. \quad \text{(A.9)}$$

Applying the same procedure, we find

$$I_{Q3B}^\mu = -i \int \frac{d^D p p^\mu}{(p^2 - m^2 + i\epsilon)((p+q)^2 - m^2 + i\epsilon)((p_B - p)^2 + i\epsilon)} \left[(1 - x_1 - x_2)p_B^\mu - x_2 q^\mu \right] =$$

$$\frac{\pi^{2}}{2(D-3)} \int_{0}^{1} \frac{dx}{(m^2 - x(1-x)t)^{3-\frac{D}{2}}} \left[p_B^\mu - (D-4)x q^\mu \right] \quad \text{(A.10)}$$

and

$$I_{Q3B}^{\mu\nu} = -i \int \frac{d^D p p^\mu p^\nu}{(p^2 - m^2 + i\epsilon)((p+q)^2 - m^2 + i\epsilon)((p_B - p)^2 + i\epsilon)} \left[(1 - x_1 - x_2)p_B^\mu - x_2 q^\mu \right] \times \left[q_B^\nu - (D-4)x q_B^\nu \right] =$$

$$\frac{\pi^{2}}{2(D-2)(D-3)} \int_{0}^{1} \frac{dx}{(m^2 - x(1-x)t)^{3-\frac{D}{2}}} \left[2p_B^\mu p_B^\nu - (D-4)x (p_B^\mu q_B^\nu + q_B^\mu p_B^\nu) \right] + (D-4)(D-3)x^2 q_\nu q^\nu + (D-3)g^{\mu\nu} \left(m^2 - x(1-x)t\right) \quad \text{(A.11)}$$

In the massless case we have

$$I_{Q3B} \mid_{m=0} = I_{3B} = -2 \left( \frac{D-3}{D-4} \right) \frac{I_2}{t}, \quad \text{(A.12)}$$

$$I_{Q3B}^\mu \mid_{m=0} = I_{3B}^\mu = \left(q^\mu - \frac{2p_B^\mu}{D-4} \right) \frac{I_2}{t}, \quad \text{(A.13)}$$

$$I_{Q3B}^{\mu\nu} \mid_{m=0} = I_{3B}^{\mu\nu} = \left[\frac{1}{(D-2)} \left( \frac{1}{2} g^{\mu\nu} + \frac{p_B^\mu q^\nu + p_B^\nu q^\mu}{t} \right) - \frac{q^\mu q^\nu}{2t} - \frac{4p_B^\mu p_B^\nu}{(D-2)(D-4)t} \right] I_2. \quad \text{(A.14)}$$
Let us now consider the case of two gluon intermediate state. To get the contribution of the diagram in Fig. 3(a), besides the integrals \( I_2 \) (A.4), \( I_\mu^2 \) (A.5) and \( I_{\mu\nu}^2 \) (A.6) we need

\[
I_G^3 B = -i \int \frac{d^D k}{(k^2 + i\varepsilon) ((k + q)^2 + i\varepsilon) ((p_B - k)^2 - m^2 + i\varepsilon)} =
\]

\[
- \pi \frac{D}{2} \Gamma \left(3 - \frac{D}{2}\right) \int_0^1 \int_0^1 \frac{d\rho_2}{R_G^{3 - \frac{D}{2}}} ,
\]

(A.15)

where

\[
R_G^3 = m^2 x_1^2 - x_2 (1 - x_1 - x_2) t ,
\]

(A.16)

\[
I_\mu^G_3 B = -i \int \frac{d^D k k^\mu}{(k^2 + i\varepsilon) ((k + q)^2 + i\varepsilon) ((p_B - k)^2 - m^2 + i\varepsilon)} =
\]

\[
- \pi \frac{D}{2} \Gamma \left(3 - \frac{D}{2}\right) \int_0^1 \int_0^1 \frac{d\rho_2}{R_G^{3 - \frac{D}{2}}} (x_1 p_B^\mu - x_2 q^\mu) ,
\]

(A.17)

\[
I_{\mu\nu}^G_3 B = -i \int \frac{d^D k k^\mu k^\nu}{(k^2 + i\varepsilon) ((k + q)^2 + i\varepsilon) ((p_B - k)^2 - m^2 + i\varepsilon)} =
\]

\[
- \pi \frac{D}{2} \Gamma \left(3 - \frac{D}{2}\right) \int_0^1 \int_0^1 \frac{d\rho_2}{R_G^{3 - \frac{D}{2}}} \left[ (x_1 p_B^\mu - x_2 q^\mu) (x_1 p_B^\nu - x_2 q^\nu) - \frac{g_{\mu\nu}}{4 - D} R_G \right] ,
\]

(A.18)

and integrals \( I_{G3A} \), \( I_\mu^G_{3A} \) and \( I_{\mu\nu}^G_{3A} \) which are obtained from eq.s (A.15) – (A18) by replacing respectively \( p_B \) and \( q \) with \( p_A \) and \( -q \). In the zero mass limit we have

\[
I_{G3B}|_{m=0} = I_{3B} \, , \quad I_{G3B}|_{m=0} = I_{3B}^\mu \, , \quad I_{G3B}|_{m=0} = I_{3B}^{\mu\nu} ,
\]

(A.19)

where \( I_{3B} \), \( I_{3B}^\mu \) and \( I_{3B}^{\mu\nu} \) are given by formulas (A.12) – (A.14). The calculation of all the integrals above listed is quite straightforward.

We also have to consider the following more complicated integral:

\[
I_G^3 \Box =
\]

\[
- i \int \frac{d^D k}{(k^2 + i\varepsilon) ((k + q)^2 + i\varepsilon) ((k + p_A)^2 - m_A^2 + i\varepsilon) ((k - p_B)^2 - m_B^2 + i\varepsilon)} ;
\]

(A.20)

fortunately, we need only its asymptotic behaviour at

\[
s = (p_A + p_B)^2 \gg -t \sim m_A^2 \sim m_B^2 .
\]
We describe its calculation with some details. After integration over $k$ with the help of the usual Feynman parametrization we obtain

$$I_{G\Box} = \pi^{\frac{D}{2}} \Gamma \left(4 - \frac{D}{2}\right) \int_0^1 \int_0^1 \int_0^1 \frac{dx_1 dx_2 dx_3 \theta(1 - x_1 - x_2 - x_3)}{R_{G4}^{4 - \frac{D}{2}}} , \quad (A.21)$$

where

$$R_{G4} = -x_1 x_2 s - x_3 (1 - x_1 - x_2 - x_3) t + (x_1 + x_2) \left((x_1 m_A^2 + x_2 m_B^2)\right) . \quad (A.22)$$

Let us introduce new variables through relations

$$x_1 = zu , \quad x_2 = (1 - z)u , \quad x_3 = x . \quad (A.23)$$

In terms of these variables we have

$$R_{G4} = -z(1 - z)u^2 s - x(1 - x - u) t + u^2 \left(z m_A^2 + (1 - z) m_B^2\right) . \quad (A.24)$$

Dividing the region of integration over $z$ into three subregions:

$$\int_0^1 dz = \int_0^\delta dz + \int_{\delta}^{1-\delta} dz + \int_{1-\delta}^1 dz , \quad (A.25)$$

where

$$1 \gg \delta \gg \frac{|t|}{s} \sim \frac{m_A^2}{s} \sim \frac{m_B^2}{s} ,$$

we can use different approximations for $R_{G4}$ in each of them:

$$R_{G4} \approx -z u^2 s - x(1 - x - u) t + u^2 m_B^2 \quad (A.26)$$

in the first subregion,

$$R_{G4} \approx -z(1 - z)u^2 s - x(1 - x - u) t \quad (A.27)$$

in the second and

$$R_{G4} \approx -(1 - z)u^2 s - x(1 - x - u) t + u^2 m_A^2 \quad (A.28)$$

in the third. As $R_{G4}$ depends on $m_B^2$ in the first subregion only and on $m_A^2$ in the third only, we can write $I_{G\Box} = \Box$ as the sum of three terms:

$$I_{G\Box} \approx I_\Box + \Delta_B + \Delta_A . \quad (A.29)$$
Here $I_{\Box}$ is $I_{G\Box}$ in the massless case, $\triangle_B$ is given by

$$\triangle_B \approx \pi^2 \Gamma \left( 4 - \frac{D}{2} \right) \int_0^1 u du \int_0^{1-u} dx \int_0^\delta dz \left[ \frac{1}{(-zu^2 s - x(1-x-u)t + u^2 m_B^2)^{4-D}/2} \right] \approx \pi^2 \Gamma \left( 3 - \frac{D}{2} \right) \int_0^1 \frac{du}{u} \int_0^{1-u} dx$$

and $\triangle_A$ can be obtained from $\triangle_B$ by substituting $m_B$ with $m_A$. The integral $I_{\Box}$ was calculated in ref. [4]:

$$I_{\Box} = -2(D-3) \left[ \ln \left( \frac{-s}{-t} \right) - 2\psi \left( \frac{D}{2} - 2 \right) + \psi \left( 3 - \frac{D}{2} \right) + \psi(1) \right] \frac{I_2}{st}, \quad (A.31)$$

where $\psi(z) = \frac{\Gamma'(z)}{\Gamma(z)}$ and $I_2$ is given by eq. (A.4).

Finally, substitution $p_B \leftrightarrow -p'_B = -(p_B + q)$ in eq.(A.20) leads to the last integral we need: it can be obtained from $I_{G\Box}$ simply by changing $s$ with $u \approx -s$.

At last, in calculating the contribution of the diagram in Fig. 3(b) in the case of two gluon intermediate state we meet again the integrals $I_{G3B}$, $I_{G3B}^\mu$ and $I_{G3B}^{\mu\nu}$, presented in eq.s (A.15), (A.17) and (A.18) correspondingly.
