Abstract

Cardiac smooth muscle tumors are rare; three different clinical settings for these tumors have been reported, including benign metastasizing leiomyoma from the uterus, primary cardiac leiomyoma and leiomyosarcoma, and intravenous cardiac extension of pelvic leiomyoma, which is the most common. We present a case of a 56-year-old woman with a benign metastasizing leiomyoma to the heart without associated pulmonary localization 15 years after endoscopic vaginal myomectomy of polymyomatous uterus. Immunohistochemical stains for H-Caldesmon, Desmin, and estrogen, progesterone receptors were positive, indicating a smooth muscle tumor of uterine origin. To our knowledge, this is only the fifth reported case of benign metastasizing leiomyoma to the heart with histological proof and the first case of earlier onset cardiac metastasis without pulmonary metastasis localization. It illustrates that benign metastasizing leiomyoma should be included in the differential diagnosis of cardiac tumors in patients with a history of surgery uterine leiomyoma perfectly benign.

Keywords: Heart; Benign metastasizing leiomyoma; Uterine surgery

Introduction

Primary cardiac tumors are rare, and most cardiac tumors are secondary to metastatic disease [1]. Smooth muscle tumors of the heart are extremely rare. Three different clinical settings for cardiac smooth muscle tumors have been reported: intravenous cardiac extension of pelvic leiomyomas [2] benign metastasizing leiomyomas from the uterus [1,3,4] and primary cardiac leiomyomas and leiomyosarcomas [5]. Here we report a rare entity of metastasizing leiomyoma to the heart with review of the literature.

Case Presentation

A 56-year-old woman presented at a provincial hospital with dyspnea and shortness of breath. On imaging, she was found to have a right atrial mass initially thought to be a thrombus. She was subsequently referred to university hospital center (CHU Ibn Sina, Rabat) for further workup and management. Cardiac Magnetic Resonance Imaging (MRI) showed a monolobed, pedunculated, mobile, well-circumscribed mass attached to the intra-atrial septum. The resected tumor was sent to us for histological confirmation. Pulmonary radiological exploration did not find a suspicious mass.

Additional history was pursued as part of the pathologic workup, and it was determined that the patient had undergone a uterine surgery endoscopic vaginal of polymyomatous uterine 15 years earlier at the age of 41 years. The uterine mass operated on was a leiomyoma with no malignant features; no necrosis, atypia, or increased mitotic activity was seen. The patient lost to follow up until she consulted for her cardiac symptomatology resulting in a discovery of mass in the right atrium.

The 8cm x 5cm x 3cm resected cardiac tumor was solid, gray-white, and homogeneous with no hemorrhage or necrosis (Figure 1). Microscopically, the tumor was composed of bundles of bland spindle cells with “cigar-shaped nuclei”, no nuclear atypia or necrosis, and only rare mitoses (less than 1/10 high-power fields) (Figure 2). Immunohistochemically, the spindle tumor cells expressed H-Caldesmon (Figure 3) and Desmin (Figure 4) and were negative for S100 (Figure 5) Protein. MIB-1 immunohistochemical fields) (Figure 1).
staining showed low proliferative activity, with less than 1% MIB-1-positive cells. The tumor cells were strongly positive for Estrogen Receptors (ER) and for Progesterone Receptors (PR) (Figure 6 and 7), supportive of uterine origin. The patient is alive and well 16 months after resection of the cardiac tumor, with no evidence of further metastasis.

**Discussion**

Benign metastatic leiomyoma is a rare pathology and its terminology is even debated, because the occurrence of metastasis to contradict their histologically benign character [6].

Benign metastasizing leiomyoma is an extrauterine smooth muscle tumor that occurs in patients with a current or prior history of uterine leiomyoma [7-9]. It has been reported in multiple locations, with the lung being the most common metastatic site [7-9], but metastases have also been reported in the skull base [10], spine [11], rib [11], vertebrae [11], lymph nodes [12], and pelvis [13]. Of smooth muscle tumors found in the heart, three types of tumors have been reported: primary cardiac smooth muscle tumors (leiomyoma or leiomyosarcoma) [5], intravenous smooth muscle tumors with intracardiac extension [2,5], and benign metastasizing leiomyoma [1,3,4]. Although all three entities are rare, intravenous extension into the heart is the most common, with more than 100 reported cases since the early 1900s [2], and the least reported type is benign metastasizing leiomyoma. It is not excluded, without being proven, that their physiopathology is common [14,15]. Furthermore, it is necessary to confirm the diagnosis by histological examination in order to rule out the differential diagnosis of leiomyosarcoma, which may have the same clinical characteristics as benign metastatic leiomyoma [16-17]. To the best of our knowledge, there are only four prior case reports of benign metastasizing leiomyoma to the heart (Table 1) [1,3,4]. Galvin et al. reported a case of a 41-year-old woman with an isolated right ventricular metastasis who had undergone a hysterectomy 3 months prior [1]. A benign leiomyoma was found in the resected uterus, which had been present 7 years prior at cesarean section. The cardiac tumor, a pedunculated mass attached to the interventricular septum, was resected and diagnosed as a benign leiomyoma. No intravenous leiomyoma was found. The cardiac tumor was ER- and PR-positive. Takemura et al. described a case of a 44-year-old woman who presented with dyspnea and a cardiac murmur after having had a hysterectomy for a leiomyoma.
may be long-delayed, prolonged clinical follow-up is recommended. Since cardiac metastasis is generally more aggressive compared to the indolent course seen in benign metastasizing leiomyomata [15]. Our case illustrates the possibility of under-interpretation of leiomyosarcoma should be considered. It is widely accepted that mitotic rate, cytologic atypia, and presence of coagulative necrosis are the most important predictors of malignant potential in uterine smooth muscle tumors. When metastasis occurs with malignant lesions, the clinical course is generally more aggressive compared to the indolent course seen in benign metastasizing leiomyomata [15]. Our case illustrates the indolent course these tumors can take, even with metachronous pulmonary and cardiac metastases.

### Conclusion

This case illustrates that smooth muscle tumors of the uterus may rarely metastasize to the heart, particularly in the situation no associated with lung metastasis. Including our case, the only one of four cases having pulmonary exploration. Since cardiac metastasis may be long-delayed, prolonged clinical follow-up is recommended.
