Citrate synthase from *Synechocystis* is a distinct class of bacterial citrate synthase

Shoki Ito, Naoto Koyama & Takashi Osanai

Citrate synthase (CS, EC 2.3.3.1) catalyses the initial reaction of the tricarboxylic acid (TCA) cycle: oxaloacetate + acetyl-CoA + H₂O → citrate + CoA-SH. Different bacterial CSs have been characterised, and studies have shown that the biochemical properties of CSs from Gram-positive bacteria and Gram-negative bacteria exhibit some differences. CSs from Gram-negative bacteria are inhibited by NADH, whereas CSs from Gram-positive bacteria are not. However, the biochemical properties of cyanobacterial CSs have not been well-characterised.

Photoautotrophic cyanobacteria have been evaluated for use in the sustainable production of bioplastics and biofuels from carbon dioxide using light energy. *Synechocystis* sp. PCC 6803 (hereafter, *Synechocystis* 6803) is a unicellular cyanobacterium that has been widely studied for use in metabolite production. *Synechocystis* 6803 exhibits suitable characteristics as a host for metabolite production such as rapid growth and natural transformation capability. Various genetic toolsets have been developed for *Synechocystis* 6803. This freshwater cyanobacterium can also grow in artificial seawater supplemented with nitrogen and phosphorus. Under dark and anaerobic conditions, *Synechocystis* 6803 produces organic acids such as d-lactate and succinate, which are used in bioplastics production (Fig. 1). In *Synechocystis* 6803, biochemical analyses of a phosphoenolpyruvate carboxylase (encoded by *pps*, sll0920) being the rate-limiting enzyme in succinate production and d-lactate dehydrogenase (encoded by *ddh*, slr1556) catalysing the final reaction in d-lactate production have been performed (Fig. 1). These reports identified the enzymatic properties and the critical amino acid residues regulating the enzymatic activities, and emphasised the importance of biochemical studies of this cyanobacterium. For example, we have previously indicated that lower activity of d-lactate dehydrogenase (Ddh) from *Synechocystis* 6803 compared to other bacterial Ddh is one of the weak points of d-lactate production using *Synechocystis* 6803. We have indicated that Ddh from *Synechocystis* 6803 also catalyses the reaction from oxaloacetate to malate and an amino acid substitution alters the substrate specificity of Ddh.

Characterising acetyl-CoA metabolism and the enzymes involved is crucial for understanding the basic science of cyanobacteria and its potential practical applications. The intracellular acetyl-CoA concentration of *Synechocystis* 6803 is much higher compared to those of other cyanobacteria. The production of...
polyhydroxybutyrate (PHB)\textsuperscript{14–16}, 3-hydroxybutyrate (3HB)\textsuperscript{17}, \(n\)-butanol\textsuperscript{18}, and 3-hydroxypropionic acid (3HP)\textsuperscript{19,20} from acetyl-CoA in \textit{Synechocystis} 6803 has been studied (Fig. 1). Ethylene production from the TCA cycle intermediates in \textit{Synechocystis} 6803 has also been demonstrated (Fig. 1)\textsuperscript{21,22}. Despite these metabolic engineering applications, few studies have conducted biochemical analysis using acetyl-CoA as a substrate in cyanobacterium. In this study, we performed biochemical analyses of \textit{Sy}CS (encoded by \textit{gltA}, sll0401) (Fig. 1) and compared its properties with those of other bacterial CSs.

Results

Purification and kinetic analyses of \textit{Sy}CS. For biochemical analysis of \textit{Sy}CS, glutathione-S-transferase (GST)-tagged \textit{Sy}CS was purified from \textit{Escherichia coli} by affinity chromatography (Fig. 2a). The optimal conditions at which \textit{Sy}CS showed maximal activity were 37 °C and pH 7.5 (Fig. 2b,c). Therefore, subsequent analysis of \textit{Sy}CS was conducted under these conditions. To calculate the kinetic parameters of \textit{Sy}CS, saturation curves of \textit{Sy}CS for both substrates were drawn (Fig. 3). The observed \(K_m\) value for oxaloacetate was 91 ± 11 \(\mu\)M and the \(k_{cat}\) value for oxaloacetate was 2.76 ± 0.26 \(s^{-1}\) (Table 1). The \(k_{cat}/K_m\) value of \textit{Sy}CS for oxaloacetate was 30.50 ± 3.17 \(s^{-1}\)\(\mu\)M\(^{-1}\) (Table 1). Similarly, for acetyl-CoA, the \(K_m\) value was 220 ± 77 \(\mu\)M and the \(k_{cat}\) value was 2.51 ± 0.24 \(s^{-1}\) (Table 1). The \(k_{cat}/K_m\) value of \textit{Sy}CS for acetyl-CoA was 12.07 ± 2.95 \(s^{-1}\)\(\mu\)M\(^{-1}\) (Table 1). \textit{Sy}CS showed no catalytic activity for the backward reaction, generating acetyl-CoA and oxaloacetate from citrate and CoA.

Effects of ions on \textit{Sy}CS activity. The effects of monovalent and divalent salts on \textit{Sy}CS activity were examined. \textit{Sy}CS activity was altered by monovalent and divalent salts, which was affected by the concentration of substrates (Fig. 4). At a saturated concentration of both substrates in the absence of effectors, \textit{Sy}CS activity increased to 188% in the presence of 100 mM KCl, 205% in the presence of 100 mM NaCl, 391% in the presence of 100 mM MgCl\(_2\), and 251% in the presence of 100 mM CaCl\(_2\), while enzyme activity was decreased to 48% in the presence of 100 mM MnCl\(_2\) (Fig. 4). At the half-saturated concentration of both substrates in the absence of effectors, \textit{Sy}CS activity increased to 345% in the presence of 100 mM KCl, 336% in the presence of 100 mM NaCl, 1,463% in the presence of 100 mM MgCl\(_2\), and 1,050% in the presence of 100 mM CaCl\(_2\), while enzyme activity was decreased to 37% in the presence of 100 mM MnCl\(_2\) (Fig. 4).

The activation of \textit{Sy}CS by monovalent and divalent salts was affected by the pH (Fig. 5). In KCl, \textit{Sy}CS activation was concentration-dependent at both pH 7.0 and pH 8.5 (Fig. 5a). The activity of \textit{Sy}CS increased linearly with increasing concentrations of NaCl at pH 7.0 (Fig. 5b). At pH 8.5, \textit{Sy}CS activity did not increase up to 50 mM NaCl; however, it increased by 2.4-fold in the presence of 100 mM NaCl (Fig. 5b). The activation of \textit{Sy}CS by 100 mM monovalent salts at pH 8.5 was greater than that at pH 7.0 (Fig. 5a,b). The activation of \textit{Sy}CS peaked at 20 mM MgCl\(_2\) at both pH 7.0 and pH 8.5 (Fig. 5c). The activation of \textit{Sy}CS peaked at 20 mM CaCl\(_2\) at pH 8.5 and at 50 mM CaCl\(_2\) at pH 7.0 (Fig. 5d). In contrast to monovalent salts, the activation of \textit{Sy}CS by 100 mM divalent salts at pH 7.0 was greater than that at pH 8.5 (Fig. 5c,d).

Regulation of \textit{Sy}CS activity by metabolites. \textit{Sy}CS activity was also altered by different metabolites (Fig. 6). In the presence of 5 mM phosphoenolpyruvate (PEP), citrate (CIT), and 2-oxoglutarate (2OG), \textit{Sy}CS activity markedly decreased to 14%, 1%, and 2%, respectively (Fig. 6). Although PEP is a metabolite in

**Figure 1.** Metabolic map around the TCA cycle in \textit{Synechocystis} sp. PCC 6803. The information of genes encoding enzymes in \textit{Synechocystis} sp. PCC 6803 were obtained by Kyoto Encyclopedia of Genes and Genomes (KEGG) database (http://www.genome.jp/kegg/). The green squares represent the useful metabolites having been reported previously. The blue dotted lines represent the synthetic reactions being catalysed by foreign enzymes. 3HB: 3-hydroxybutyrate, 3HP: 3-hydroxypropionic acid, PHB: polyhydroxybutyrate.
glycolysis, it inhibited SyCS activity (Fig. 6). To examine the changes in the kinetic parameters of SyCS, saturation curves of SyCS for both substrates in the presence of 3 mM PEP were drawn (Fig. 3). In the presence of 3 mM PEP, the $K_m$ value of SyCS for oxaloacetate was 108 ± 4 μM, the $k_{cat}$ value of SyCS for oxaloacetate decreased to 1.53 ± 0.06 s$^{-1}$, and the $k_{cat}/K_m$ value of SyCS for oxaloacetate decreased to 14.19 ± 0.99 s$^{-1}$mM$^{-1}$ (Table 1).
We purified and biochemically characterised CS from the cyanobacterium *Synechocystis* sp. PCC 6803 in this study. The *K_m* value of *Sy* CS was lower than those of reported CSs from heterotrophic bacteria (8–263 s⁻¹)²³–³⁰ (Table 1). In the presence of 5 mM ADP, the *K_m* value of *Sy* CS for acetyl-CoA was 7.39 ± 0.70 s⁻¹mM⁻¹ (Table 1). In contrast, *Sy* CS activity significantly increased to 369% in the presence of 5 mM ADP (Fig. 6). To examine changes in the kinetic parameters of *Sy* CS, the saturation curves of *Sy* CS for both substrates in the presence of 5 mM ADP were drawn (Fig. 3). In the presence of 5 mM ADP, the *K_m* value of *Sy* CS for oxaloacetate was 73 ± 11 μM, the *k_cat* value of *Sy* CS for oxaloacetate was 3.35 ± 0.54 s⁻¹, and the *k_cat/K_m* value of *Sy* CS for oxaloacetate increased to 45.65 ± 0.84 s⁻¹mM⁻¹ (Table 1). In the presence of 5 mM ADP, the *K_m* value of *Sy* CS for acetyl-CoA was 153 ± 24 μM, the *k_cat* value of *Sy* CS for acetyl-CoA was 2.99 ± 0.12 s⁻¹, and the *k_cat/K_m* value of *Sy* CS for acetyl-CoA increased to 19.90 ± 2.82 s⁻¹mM⁻¹ (Table 1). Compounds related to the TCA cycle and amino acid metabolism (pyruvate (PYR), succinate (SUC), fumarate (FUM), l-malate (MAL), and l-aspartate (ASP)) and nucleotides (ATP, AMP, NADH, NAD⁺, NADPH, and NADP⁺) did not significantly alter *Sy* CS activity (Fig. 6).

**Discussion**

We purified and biochemically characterised CS from the cyanobacterium *Synechocystis* sp. PCC 6803 in this study. The *k_cat* value of *Sy* CS was lower than those of reported CSs from heterotrophic bacteria (8–263 s⁻¹)²³–³⁰ (Table 1). The *K_m* value of *Sy* CS for acetyl-CoA was similar to that of CS from *Arthrobacter* strain DS2-3R (200 μM)²⁶ but higher than those of reported CSs from heterotrophic bacteria (14–200 μM)²³–³⁰ (Table 1). Similarly, the *K_m* value of *Sy* CS for oxaloacetate was higher than those of CSs from heterotrophic bacteria (4–20 μM)²³–³⁰ (Table 1). These observations indicate that *Sy* CS is an inefficient enzyme, similar to malate dehydrogenase from *Synechocystis* 6803 (encoded by *citH*, sl0891), which is involved in the oxidative TCA cycle (Fig. 1)⁴¹. In *Synechocystis* 6803, carbon flux through the TCA cycle is low under heterotrophic, photomixotrophic, and photoautotrophic conditions in contrast to other metabolic pathways such as the glycolysis and oxidative pentose phosphate pathways²²,³²–³⁶. The low activity of *Sy* CS may be a factor in

| Substrate     | Effector | *K_m* (μM) | *k_cat* (s⁻¹) | *k_cat/K_m* (s⁻¹mM⁻¹) |

Table 1. Kinetic parameters of *Sy* CS for oxaloacetate and acetyl-CoA. The experiment was conducted using 50 pmol of *Sy* CS, and enzymatic activity was measured under optimal conditions (37 °C and pH 7.5). The concentrations of oxaloacetate or acetyl-CoA were 1 and 0.5 mM, respectively, and the *K_m* values of CS, the saturation curves of CS, the saturation curves of CS for both substrates in the presence of 5 mM ADP were drawn (Fig. 3). In the presence of 5 mM ADP, the *K_m* value of *Sy* CS for oxaloacetate was 73 ± 11 μM, the *k_cat* value of *Sy* CS for oxaloacetate was 3.35 ± 0.54 s⁻¹, and the *k_cat/K_m* value of *Sy* CS for oxaloacetate increased to 45.65 ± 0.84 s⁻¹mM⁻¹ (Table 1). In the presence of 5 mM ADP, the *K_m* value of *Sy* CS for acetyl-CoA was 153 ± 24 μM, the *k_cat* value of *Sy* CS for acetyl-CoA was 2.99 ± 0.12 s⁻¹, and the *k_cat/K_m* value of *Sy* CS for acetyl-CoA increased to 19.90 ± 2.82 s⁻¹mM⁻¹ (Table 1).

In the presence of 5 mM ADP, the *K_m* value of *Sy* CS for acetyl-CoA was 194 ± 36 μM, the *k_cat* value of *Sy* CS for acetyl-CoA decreased to 1.42 ± 0.18 s⁻¹, and the *k_cat/K_m* value of *Sy* CS for acetyl-CoA was 7.39 ± 0.70 s⁻¹mM⁻¹ (Table 1). In contrast, *Sy* CS activity significantly increased to 369% in the presence of 5 mM ADP (Fig. 6). To examine changes in the kinetic parameters of *Sy* CS, the saturation curves of *Sy* CS for both substrates in the presence of 5 mM ADP were drawn (Fig. 3). In the presence of 5 mM ADP, the *K_m* value of *Sy* CS for oxaloacetate was 73 ± 11 μM, the *k_cat* value of *Sy* CS for oxaloacetate was 3.35 ± 0.54 s⁻¹, and the *k_cat/K_m* value of *Sy* CS for oxaloacetate increased to 45.65 ± 0.84 s⁻¹mM⁻¹ (Table 1). In the presence of 5 mM ADP, the *K_m* value of *Sy* CS for acetyl-CoA was 153 ± 24 μM, the *k_cat* value of *Sy* CS for acetyl-CoA was 2.99 ± 0.12 s⁻¹, and the *k_cat/K_m* value of *Sy* CS for acetyl-CoA increased to 19.90 ± 2.82 s⁻¹mM⁻¹ (Table 1). Compounds related to the TCA cycle and amino acid metabolism (pyruvate (PYR), succinate (SUC), fumarate (FUM), l-malate (MAL), and l-aspartate (ASP)) and nucleotides (ATP, AMP, NADH, NAD⁺, NADPH, and NADP⁺) did not significantly alter *Sy* CS activity (Fig. 6).
the observed low carbon flux through the oxidative TCA cycle in *Synechocystis* 6803. Additionally, CSs from *Thermosulfidibacter takaii* ABI70S6T and *Desulfurella acetivorans* catalyse the backward reaction, the cleavage of citrate. SyCS did not catalyse the backward reaction. This result suggests that SyCS is not involved in the reductive TCA cycle (Fig. 1).

**Figure 5.** Effect of pH on activation of SyCS by (a) KCl, (b) NaCl, (c) MgCl₂, and (d) CaCl₂. The experiment was conducted using 50 pmol of SyCS at 37°C, pH 7.0 or 8.5. The concentrations of oxaloacetate and acetyl-CoA were 1 and 0.5 mM. SyCS activity in the absence of monovalent and divalent salts was set to 100%. The data represent the mean ± SD from three independent experiments.

**Figure 6.** Effect of metabolites on SyCS activity. The experiment was conducted using 50 pmol of SyCS at 37°C, pH 7.5. The concentrations of oxaloacetate and acetyl-CoA were the *Kₘ* values, 0.091 and 0.220 mM, respectively. Concentrations of the metabolites were 5 mM. SyCS activity in the absence of metabolites was set to 100%. The data represent the mean ± SD from three independent experiments. PEP: Phosphoenolpyruvate, PYR: Pyruvate, CIT: Citrate, 2OG: 2-Oxoglutarate, SUC: Succinate, FUM: Fumarate, MAL: l-Malate, ASP: l-Aspartate. The asterisks indicate significant differences between the absence and presence of the metabolite (Student’s t test; *P* < 0.05).
Monovalent and divalent salts and cellular metabolites altered SyCS activity (Figs 4–6). Monovalent salts activate numerous bacterial CSs, while divalent salts inhibit many bacterial CSs. In contrast to other bacterial CSs, SyCS was markedly activated by the divalent salts MgCl₂ and CaCl₂ rather than monovalent salts (Fig. 4). Among divalent salts, MnCl₂ inhibited SyCS (Fig. 4). In CS from *E. coli*, a higher pH leads to greater activation by 0.1 M KCl. In SyCS, a higher pH led to greater activation by 0.1 M KCl and NaCl (Fig. 5a,b). In contrast, a lower pH led to greater activation by 0.1 M MgCl₂ and CaCl₂ (Fig. 5c,d). In monovalent and divalent salts, MgCl₂ was the strongest activator of SyCS (Figs 4 and 5). In the stroma in spinach chloroplasts, free Mg²⁺ concentration is affected by light-dark transition. It is expected that free Mg²⁺ concentration in *Synechocystis* 6803 is similarly affected by light-dark transition. Therefore, SyCS activity may also be affected by light-dark transition. NADH is a feedback inhibitor of CSs in most Gram-negative bacteria. However, SyCS was not inhibited by NADH (Fig. 6). Phylogenetic analysis revealed that SyCS belongs to a cyanobacterial clade being different from clades of Gram-positive bacteria and Gram-negative bacteria (Fig. 7). Unlike heterotrophic bacteria, cyanobacteria do not possess 2-oxoglutarate dehydrogenase in the TCA cycle, and *Synechocystis* 6803 is rerouted to produce succinate by two alternate pathways (Fig. 1). Isocitrate dehydrogenase from *Synechocystis* 6803 (encoded by icd, slr1289) is specific to NADP⁺ and generates NADPH but not NADH. Additionally, malate dehydrogenase from *Synechocystis* 6803 (encoded by citH, slr0891) specifically catalyses the reductive reaction generating NAD⁺ but not NADH. These previous studies explain why NADH does not function as a feedback inhibitor of SyCS. CIT and 2OG are feedback inhibitors of SyCS and several bacterial CSs. We demonstrated that PEP is a unique inhibitor of SyCS (Fig. 6). In the presence of PEP, the *K₅* values of SyCS for both substrates were unchanged and the *k_cat/k_m* values of SyCS for both substrates were decreased (Table 1). These results indicate that PEP is a non-competitive inhibitor of SyCS. Phosphoenolpyruvate carboxylase from *Synechocystis* 6803 (encoded by pps, slr0920) catalyses the carboxylation of PEP to generate oxaloacetate, a substrate of SyCS (encoded by gltA, slr0401) and malate dehydrogenase (encoded by citH, slr0891) (Fig. 1). The reaction catalysed by phosphoenolpyruvate carboxylase (encoded by pps, slr0920) (Fig. 1) is the rate-limiting step in the production of succinate via the reductive TCA cycle in *Synechocystis* 6803. PEP has been suggested to regulate both the oxidative and reductive TCA cycle in *Synechocystis* 6803. The intracellular concentrations of CIT and PEP are much higher than that of 2OG (CIT: 7.3 times, PEP: 8.5 times). In inhibitors of metabolites, CIT and PEP may have large inhibitory effects on SyCS under in vivo conditions. While ATP did not alter SyCS activity (Fig. 6), it acts as a feedback inhibitor for other CSs because of its structural similarity with acetyl-CoA. AMP upregulates the activity of CSs from *Azotobacter vinelandii* and *Streptomyces diastaticus* No. 7 strain M1033. However, SyCS was activated by ADP rather than AMP (Fig. 6). ADP enhanced the catalytic efficiency (ΔG°/K₅) of SyCS (Table 1). Generally, ADP inhibits CS for the same reason as ATP. Our study indicates that ADP is a unique activator of SyCS. *Synechocystis* 6803 has more ADP than ATP in the cells in contrast to *E. coli* whose CS is inhibited by ATP and hardly affected by ADP. This may be a reason that SyCS is affected by not ATP but ADP.

Taken together, we found that the characteristics of SyCS significantly differ from those of other bacterial CSs.
Methods
Construction of the recombinant SyCS expression vector. The region containing gltA (sll0401, encoding SyCS) in the Synechocystis 6803 genome was commercially synthesized by Eurofin Genomics Japan (Tokyo, Japan) and cloned into the BamHI-XhoI site of the pGEX5X-1 vector (GE Healthcare, Little Chalfont, UK).

Affinity purification of recombinant proteins. The expression vector was transformed into E. coli DH5α cells (TakaraBio, Shiga, Japan). A 2-L culture of transformed DH5α cells in LB media was prepared by shaking at 125 rpm at 30 °C overnight. Expression of the recombinant proteins was induced by 0.01 mM isopropyl β-D-1-thiogalactopyranoside (Wako Chemicals, Osaka, Japan). Affinity purification of the recombinant proteins was performed as described previously. The DH5α cells were lysed by sonication (VC-750, EYELA, Tokyo, Japan) for 200 s at 20% intensity. The supernatant was collected after centrifugation (5,800 × g for 2 min at 4 °C) and 560 µL of Glutathione-Sepharose 4B resin (GE Healthcare) was added to the supernatant. The mixture was incubated on ice for 30 min with constant shaking. After 30 min, 1 mM ATP and 1 mM MgSO4·7H2O were added to the mixture and shaken for 30 min at 37 °C. After centrifugation (5,800 × g for 2 min at 4 °C) to remove the supernatant, the resin was re-suspended in 700 µL of PBS-T (1.37 M NaCl, 27 mM KCl, 81 mM Na2HPO4·12H2O, 14.7 mM KH2PO4, and 0.05% Tween-20) with 1 mM ATP/1 mM MgSO4·7H2O. The resin was washed 10 times using PBS-T, and the recombinant proteins were eluted with 700 µL of GST elution buffer (50 mM Tris–HCl, pH 8.0, and 10 mM reduced glutathione) four times. The eluted protein fractions were concentrated using a VivaSpin 5000 MWCO device (Sartorius, Göttingen, Germany). The protein concentration was measured using a Pierce BCA Protein Assay Kit (Rockford, IL, USA). To evaluate protein purity, SDS-PAGE followed by staining with InstantBlue (Expedition Protein Solutions, San Diego, CA, USA) was performed.

Enzyme assays. The enzyme activity of SyCS for the forward reaction, generating citrate and CoA from acetyl-CoA and oxaloacetate, was assessed as described previously. Enzyme activity was calculated by measuring the change in A412 using a Hitachi U-3310 spectrophotometer (Tokyo, Japan). The purified SyCS proteins were added to 1 mL assay solution (50 mM Tris–HCl containing various concentrations of oxaloacetate, various concentrations of acetyl-CoA, and 0.2 mM DTNB). The Kcat and Vmax values of SyCS were calculated using a Lineweaver–Burk double reciprocal plot. The Kcat values of SyCS were determined from the Vmax values of SyCS. The enzyme activity of SyCS for the backward reaction, generating acetyl-CoA and oxaloacetate from citrate and CoA, was assessed as described previously by measuring the change in A365 using a Hitachi U-3310 spectrophotometer. The purified SyCS proteins were added to 1 mL assay solution (50 mM Tris–HCl containing 1 mM CoA, 1 mM citrate, 5 mM MgCl2, 0.5 mM NADH, and 20 U malate dehydrogenase (Oriental Yeast, Tokyo, Japan)).

Acknowledgements
This work was supported by the Ministry of Education, Culture, Sports, Science, and Technology, Japan, by a grant to T.O., from JST-ALCA (Japan Science and Technology Agency, Advanced Low Carbon Technology Research and Development Program, the project name is “Production of cyanobacterial succinate by the genetic engineering of transcriptional regulators and circadian clocks”) (Grant Number JPMJAL1306) and from by Japan Society for the Promotion of Science, KAKENHI Grant-in-Aid for Scientific Research on Innovative Areas (Grant Number 16H06559). No conflicts of interest to declare. All authors contributed to the work and approved the submission of the manuscript.

Author Contributions
S.I. designed the research, performed the experiments, analysed the data, and wrote the manuscript. N.K. performed the experiments and analysed the data. T.O. designed the research and wrote the manuscript.
