MIXED ARTIN–TATE MOTIVES WITH FINITE COEFFICIENTS

LEONID POSITSELSKI

ABSTRACT. The goal of this paper is to give an explicit description of the triangulated categories of Tate and Artin–Tate motives with finite coefficients \( \mathbb{Z}/m \) over a field \( K \) containing a primitive \( m \)-root of unity as the derived categories of exact categories of filtered modules over the absolute Galois group of \( K \) with certain restrictions on the successive quotients. This description is conditional upon (and its validity is equivalent to) certain Koszulity hypotheses about the Milnor K-theory/Galois cohomology of \( K \). This paper also purports to explain what it means for an arbitrary nonnegatively graded ring to be Koszul. Tate motives with integral coefficients are discussed in the “Conclusions” section.

0.0. In the paper [2] published in 1987, A. Beilinson formulated his famous conjectures on the properties of hypothetical categories of mixed motivic sheaves over a scheme. In addition to the classical case of motives with rational coefficients, some conjectures about the category of motives with a finite coefficient ring \( \mathbb{Z}/m \) were proposed there. Equivalent conjectures describing motivic complexes with finite coefficients were earlier formulated by S. Lichtenbaum in [27].

In the subsequent works of V. Voevodsky [49] and others, triangulated categories \( \mathcal{DM}(K, k) \) of motives over \( K \) were constructed (assuming only the resolution of singularities) for any field \( K \) and any coefficient ring \( k = \mathbb{Z}, \mathbb{Q}, \) or \( \mathbb{Z}/m \). Beilinson predicted existence of abelian categories of mixed motives; the triangulated categories now known would then be equivalent to the derived categories of those abelian categories. The problem of constructing such categories of mixed motives, or finding them as subcategories of the triangulated categories of motives, remains open. In this paper we study the cases of mixed Tate and Artin–Tate motives over a field with finite coefficients and discuss the related homological algebra formalism in general.

0.1. There are three essentially independent conditions one has to verify in order to establish that a triangulated category \( \mathcal{D} \) is equivalent to the derived category of an abelian category. First one has to find an abelian subcategory \( \mathcal{A} \subset \mathcal{D} \), or, more technically speaking, define a \( t \)-structure \([4]\) on the category \( \mathcal{D} \). Secondly, one has to check that this \( t \)-structure is “of the derived type” \([5, \text{Section } 4.0]\), i.e., the natural homomorphisms of the Ext groups \( \text{Ext}^*_\mathcal{D}(X, Y) \to \text{Hom}_\mathcal{D}(X, Y[n]) \) are isomorphisms for all \( X, Y \in \mathcal{A} \). Thirdly, one has to construct a triangulated functor \( \mathcal{D}^b(\mathcal{A}) \to \mathcal{D} \) compatible with the embeddings of \( \mathcal{A} \) into \( \mathcal{D}^b(\mathcal{A}) \) and \( \mathcal{D} \).

Very roughly, given a full subcategory \( \mathcal{A} \subset \mathcal{D} \), the condition that \( \mathcal{A} \) is the heart of a \( t \)-structure on \( \mathcal{D} \) is a restriction on the groups \( \text{Hom}_\mathcal{D}(X, Y[n]) \) for \( n \leq 0 \), while the condition that the \( t \)-structure is of the derived type is a restriction on the groups \( \text{Hom}_\mathcal{D}(X, Y[n]) \) for \( n \geq 2 \). The former condition amounts to the existence of \textit{canonical filtrations} on the objects of \( \mathcal{D} \) with subquotients in \( \mathcal{A} \), while the latter condition is equivalent to the existence of \textit{silly filtrations}. As to the problem of existence of a triangulated functor from \( \mathcal{D}^b(\mathcal{A}) \) to \( \mathcal{D} \), it can be viewed independently of the choice of the subcategory \( \mathcal{A} \subset \mathcal{D} \) as arising solely from shortcomings of the notion of a triangulated category per se.

0.2. Let us discuss the canonical and silly filtrations in some more detail. Suppose we are given a complex \( \cdots \to X^{i-1} \to X^i \to \cdots \) with objects and morphisms from an abelian category \( \mathcal{A} \). Then there are two filtrations which one can define on the complex \( X^\bullet \): the \textit{canonical filtration} by the subcomplexes \( \cdots \to X^{i-1} \to \text{Ker } d_i \to 0 \) and the \textit{silly filtration} by the subcomplexes \( 0 \to X^i \to X^{i+1} \to \cdots \). The former filtration is increasing when \( i \) increases, while the latter one is decreasing; the successive quotients of the former filtration are the cohomology objects \( H^i(X^\bullet) \), while the successive quotients of the latter one are the terms \( X^i \) of the complex \( X^\bullet \). The canonical filtration owes its name to the fact that it does not depend on the choice of a particular complex inside a given quasi-isomorphism class and therefore
is uniquely (and functorially) defined on objects of the derived category $\mathcal{D}(\mathcal{A})$. The silly filtration on an object of the derived category is not unique; nevertheless, it is sensible to ask about its existence.

A typical example when the canonical filtrations do exist, but the silly filtrations may not is the following one. Let $\mathcal{A}$ be an abelian subcategory of an abelian category $\mathcal{B}$; consider the derived category $\mathcal{D}^b(\mathcal{B})$ of bounded complexes in the category $\mathcal{B}$ with cohomology in the subcategory $\mathcal{A}$. Then one can see that the silly filtrations exist in $\mathcal{D}^b(\mathcal{A})$ if and only if the natural functor $\mathcal{D}^b(\mathcal{A}) \to \mathcal{D}^b(\mathcal{B})$ is an equivalence of categories, which means that the Ext groups between the objects of $\mathcal{A}$ computed in the larger category $\mathcal{B}$ should coincide with those computed in $\mathcal{A}$. On the other hand, the canonical filtrations may not exist on complexes whose terms belong to an additive category which is not abelian.

0.3. The silly filtrations condition can be stated in several equivalent forms as a condition on a full subcategory $\mathcal{M}$ closed under extensions in a triangulated category $\mathcal{D}$. One of these formulations is quite simply that any element of the group $\text{Hom}_{\mathcal{D}}(X, Y[n])$ with $X, Y \in \mathcal{M}$ and $n \geq 2$ is the composition of such elements of degree $n = 1$. This makes it possible to consider this condition independently of the condition that $\mathcal{M}$ is the heart of a t-structure.

Given a t-structure with the heart $\mathcal{A}$ on a triangulated category $\mathcal{D}$ and assuming the existence of a certain refinement [3], [32] of the triangulated category structure on $\mathcal{D}$ (which does exist, at least, for all triangulated categories of algebraic origin), one can construct a triangulated functor $\mathcal{D}^b(\mathcal{A}) \to \mathcal{D}$. This functor is an equivalence of triangulated categories if and only if the t-structure is of the derived type, i.e., the silly filtrations, or Ext decomposition, condition holds. This answers, in theory, our question when a triangulated category is equivalent to the derived category of an abelian category.

Notice the difference between our silly filtrations and the “weight structures” of Bondarko [13]: the orthogonality condition from the definition in [13] is not assumed, and does not hold, in the situations considered in this paper. Indeed, the question of existence of silly filtrations on objects of a triangulated category with respect to a generating full subcategory (closed under extensions) that we are interested in here becomes trivial when the orthogonality, i.e., the vanishing of $\text{Hom}_{\mathcal{D}}(X, Y[n])$ for $X, Y \in \mathcal{M}$ and $n \geq 1$, is assumed.

0.4. Let us discuss the case of Tate motives with rational coefficients first. One can define the category of mixed Tate motives as the minimal subcategory of Voevodsky’s triangulated category $\mathcal{D}_M = \mathcal{D}_M(K, \mathbb{Q})$ containing the Tate objects $\mathbb{Q}(i)$ and closed under extensions. Beilinson’s conjectures claim—and Voevodsky for his triangulated category of motives proves—that the Ext spaces between the Tate objects are isomorphic to the appropriate pieces of the algebraic K-theory groups of the field $K$. This means that the first problem one encounters is to prove that the pieces of the algebraic K-theory corresponding to the spaces $\text{Hom}_{\mathcal{D}_M}(\mathbb{Q}(i), \mathbb{Q}(j)[n])$ with negative numbers $n$, and actually also with $n = 0$ and $i \neq j$, vanish—which is the statement of the Beilinson–Soule vanishing conjectures. This is the necessary and sufficient condition for existence of a t-structure on the
triangulated subcategory of $\mathcal{DM}(K, \mathbb{Q})$ generated by the Tate objects having the above-defined category of mixed Tate motives as its heart.

As to the silly filtrations, let us note that even if the abelian category of arbitrary mixed motives does exist, the condition that the Ext spaces between the Tate objects computed in this large abelian category coincide with those with respect to the abelian category of mixed Tate motives is still highly nontrivial. This is one of Beilinson’s conjectures [2, Section 5.10.D(iv)]; it is supported by the facts that one has $\text{Hom}_{\mathcal{DM}}(\mathbb{Q}(i), \mathbb{Q}(j)[n]) = 0$ for $n > j - i$, and, most remarkably, that the diagonal Ext algebra $\bigoplus_n \text{Hom}_{\mathcal{DM}}(\mathbb{Q}, \mathbb{Q}(n)[n])$, being isomorphic to the Milnor K-theory algebra $K^M(K) \otimes_{\mathbb{Z}} \mathbb{Q}$ of the field $K$ with rational coefficients, is a quadratic algebra.

0.5. Another name for the silly filtration conjecture is the “K(π, 1)-conjecture” of Bloch and Kriz [10]. This terminology comes from the following series of examples.

Let $X$ be a connected CW-complex and $\mathcal{D}$ be the derived category of sheaves of abelian groups on $X$. Denote by $\mathcal{A} \subset \mathcal{D}$ be the abelian subcategory of locally constant sheaves. The subcategory $\mathcal{A}$ is the heart of a bounded t-structure on the full triangulated subcategory in $\mathcal{D}$ generated by $\mathcal{A}$. This t-structure is of the derived type if and only if $X$ is a K(π, 1).

Alternatively, let $\mathcal{D}$ be the derived category of sheaves of $\mathbb{Q}$-vector spaces on $X$ and $\mathcal{A} \subset \mathcal{D}$ be the abelian subcategory consisting of all unipotent local systems of finite rank. The abelian category $\mathcal{A}$ is the heart of a bounded t-structure on the full triangulated subcategory in $\mathcal{D}$ generated by $\mathcal{A}$. This t-structure is of the derived type if and only if the rational homotopy type of $X$ is a K(π, 1).

0.6. As we have already mentioned, the above homomorphisms $\text{Ext}^n_\mathcal{A}(X, Y) \to \text{Hom}_\mathcal{D}(X, Y[n])$ are isomorphisms whenever they are surjective, that is, if and only if any element of the group $\text{Hom}_\mathcal{D}(X, Y[n])$ with $X, Y \in \mathcal{A}$ and $n \geq 2$ is the composition of such elements of degree $n = 1$. In the case of mixed Tate motives, however, we only know the higher Hom spaces between the simple objects $\mathbb{Q}(i)$. One can even show that it suffices to decompose any homomorphism $X \to Y[n]$ with a simple object $X$, but the condition that any higher homomorphism between two simple objects is decomposable is not sufficient. It is not always possible to express the silly filtrations condition in terms of the algebra of higher homomorphisms between the simple objects; when it is, it typically turns out to be a Koszulity [6], [42] condition.

For mixed Tate motives with rational coefficients, such a result can be obtained in the case of a field $K$ of finite characteristic. A conjecture of Parshin and Beilinson claims that in this case the algebraic and Milnor K-theory rings with rational coefficients coincide; this means that $\text{Hom}_{\mathcal{DM}}(\mathbb{Q}(i), \mathbb{Q}(j)[n]) = 0$ unless $n = j - i$. Then the Ext spaces computed in the abelian category of mixed Tate motives are isomorphic to the higher Hom spaces in the triangulated category if and only if the diagonal Hom algebra, that is the Milnor K-theory algebra $K^M(K) \otimes_{\mathbb{Z}} \mathbb{Q}$, is Koszul.

0.7. Now let us turn to Tate motives with finite coefficients. As in the rational coefficients case, there is a spectral sequence starting from the motivic cohomology
groups $\text{Hom}_{\mathcal{DM}}(\mathbb{Z}/m, \mathbb{Z}/m(i)[n])$, where $\mathcal{DM} = \mathcal{DM}(K, \mathbb{Z}/m)$, and converging to the algebraic $K$-theory of the field $K$ with coefficients $\mathbb{Z}/m$. In particular, the diagonal cohomology algebra $\bigoplus_n \text{Hom}_{\mathcal{DM}}(\mathbb{Z}/m, \mathbb{Z}/m(n)[n])$ is isomorphic to the Milnor $K$-theory algebra $K^M(K) \otimes_{\mathbb{Z}} \mathbb{Z}/m$.

On the other hand, the Beilinson–Lichtenbaum conjectures connect motivic cohomology with Galois cohomology of the field $K$. The triangulated category of motives with finite coefficients $\mathcal{DM}(K, \mathbb{Z}/m)$ over a field $K$ of characteristic prime to $m$ comes together with the étale realization functor $\mathcal{DM}(K, \mathbb{Z}/m) \to \mathcal{D}(G_K, \mathbb{Z}/m)$ where $G_K = \text{Gal} (\overline{K}/K)$ is the absolute Galois group of $K$ and $\mathcal{D}(G_K, \mathbb{Z}/m)$ is the derived category of discrete $G_K$-modules over $\mathbb{Z}/m$. This functor sends the Tate object $\mathbb{Z}/m(i)$ to the cyclotomic $G_K$-module $\mu_m^{\otimes i}$. The conjectures claim that the étale realization functor induces isomorphisms of the higher Hom spaces as follows:

$$
\text{Hom}_{\mathcal{DM}}(\mathbb{Z}/m(i), \mathbb{Z}/m(j)[n]) \simeq H^n(G_K, \mu_m^{\otimes j-i}), \quad \text{for } n \leq j-i;
$$

$$
\text{Hom}_{\mathcal{DM}}(\mathbb{Z}/m(i), \mathbb{Z}/m(j)[n]) = 0, \quad \text{otherwise.}
$$

In particular, comparing the two formulas for the diagonal cohomology one comes to the Milnor–Bloch–Kato conjecture connecting the Galois cohomology with cyclotomic coefficients with the Milnor $K$-theory. It was proven by Voevodsky and Suslin [46] (see also [21]) that the converse implication holds as well: if the Milnor–Bloch–Kato conjecture is true for any field containing the field $K$, then the Beilinson–Lichtenbaum conjecture for the field $K$ follows.

0.8. In view of the Beilinson–Lichtenbaum formulas (0.1), it is a natural problem to give a precise description of the triangulated subcategory generated by the Tate objects in $\mathcal{DM}(K, \mathbb{Z}/m)$ in terms of the Galois group $G_K$. The question of finding an elementary construction, in terms of the Galois group, of an abelian category of mixed Tate motives with finite coefficients with the Ext spaces given by the Beilinson–Lichtenbaum formulas was posed in [2, Section 5.10.D(vi)].

As in the rational coefficients case, the minimal subcategory of $\mathcal{DM}(K, \mathbb{Z}/m)$ containing the Tate objects and closed under extensions seems to be the natural candidate for the category of mixed Tate motives. By the definition, any object of this category has a canonical filtration whose successive quotients are direct sums of the Tate objects, and this is the maximal subcategory with this property. It turns out, however, that this category is not abelian.

The reason is that it follows from the formulas (0.1) that, unlike in the rational coefficients case, for certain $i > 0$ there exists a nonzero morphism $\mathbb{Z}/m \to \mathbb{Z}/m(i)$ corresponding to an isomorphism of $G_K$-modules $\mathbb{Z}/m \simeq \mu_m^{\otimes i}$. It is easy to see that the kernel and cokernel of such a morphism in the above category of mixed Tate motives are zero, and still this morphism is not an isomorphism. In the simplest case of an algebraically closed field $K$ and a prime number $m$, this category is equivalent to the category of finite-dimensional filtered vector spaces over $\mathbb{Z}/m$.

0.9. Instead of being abelian, the category of mixed Tate motives with finite coefficients has a natural structure of an exact category. The construction of the derived
category of an abelian category can be generalized to exact categories smoothly, and, conversely, an additive subcategory of a triangulated category has a natural exact category structure if it is closed under extensions and there are no Hom groups with negative degrees between its objects. All the results about t-structures mentioned in Sections 0.1 and 0.3 can be extended to exact subcategories of triangulated categories.

0.10. Depending on the conditions on the field \( K \) and the coefficient ring \( k \), it may or may not be possible to express in a simple way all of the motivic cohomology \( \text{Hom}_{DM}(k, k(n)[i]) \), where \( DM = DM(K, k) \), in terms of the diagonal cohomology \( \text{Hom}_{DM}(k, k(n)[n]) \simeq K^M_n(K) \otimes_k k \). Various conjectures and results predict that in the following situations this should be possible:

(i) \( k = \mathbb{Q} \) and \( \text{char } K = p > 0 \);
(ii) \( k = \mathbb{Z}/p^r \) and \( \text{char } K = p > 0 \);
(iii) \( k = \mathbb{Z}/m \) and \( K \) contains a primitive root of unity of degree \( m \).

In all of these cases, the silly filtration conjecture for the mixed Tate motives over \( K \) with coefficients in \( k \) is equivalent to the Koszulity condition on the graded algebra of diagonal motivic cohomology \( K^M_n(K) \otimes_k k \).

On the other hand, in the following cases there is apparently no simple way to express the motivic cohomology in terms of its diagonal part:

(iv) \( k = \mathbb{Z}/l \) for a prime number \( l \), the field \( K \) does not contain a primitive root of unity of degree \( l \), and \( \text{char } K \neq l \);
(v) \( k = \mathbb{Q} \) and \( \text{char } K = 0 \).

In these cases, we do not know how to express the silly filtration conjecture in terms of the graded algebra of diagonal motivic cohomology \( K^M_n(K) \otimes_k k \), nor do we know whether one should expect the Milnor algebra \( K^M_n(K) \otimes_k k \) to be Koszul for any motivic reasons.

0.11. The main results of this paper are as follows.

Assuming the Beilinson–Lichtenbaum conjecture, we prove that the exact category of mixed Tate motives with coefficients in \( \mathbb{Z}/m \) is equivalent to the category of filtered modules \((N, F)\) over \( \mathbb{Z}/m \) with a discrete action of the Galois group \( G_K \) such that each quotient module \( F^i N/F^{i+1}N \) is isomorphic to a direct sum of several copies of the cyclotomic module \( \mu_m^{\otimes i} \). Furthermore, we show that if the field \( K \) contains a primitive \( m \)-root of unity, then the Ext spaces computed in this exact category are isomorphic to the higher Hom spaces in the triangulated category of motives (i.e., are given by the Beilinson–Lichtenbaum formulas) if and only if the Galois cohomology algebra \( H^*(G_K, \mathbb{Z}/m) \) is Koszul.

Recall that it was proven in the paper [42] that the Milnor–Bloch–Kato conjecture claiming the isomorphism between the Galois cohomology and the Milnor K-theory algebra modulo \( m \) follows from its low-degree part (an isomorphism in degree 2 and a monomorphism in degree 3) provided that the Milnor algebra is Koszul for all algebraic extensions of a given field. The result of this paper means that the Koszulity conjecture together with the low-degree part of the Milnor–Bloch–Kato conjecture is equivalent to the full Milnor–Bloch–Kato conjecture together with the silly filtrations condition for the exact category of mixed Tate motives.
0.12. As a generalization of mixed Tate motives, one can consider mixed Artin–Tate motives over a field $K$. These are the motives $k[L]$ of finite field extensions $L/K$, their Tate twists $k[L](i)$, and any extensions of these. Let us choose a finite Galois extension $M/K$ and restrict ourselves to the exact subcategory $\mathcal{M}$ of $\mathcal{DM}(K, k)$ formed by all the successive extensions of the objects $k[L](i)$ with $K \subset L \subset M$.

Our main conjecture about Artin–Tate motives claims that this exact subcategory satisfies the silly filtrations condition, i.e., the groups Ext in $M$ are isomorphic to the corresponding Hom groups in the triangulated category of motives $\mathcal{DM}(K, k)$. We show that in the above situations (i–iii) this conjecture is equivalent to the Koszulity condition on the algebra of diagonal Hom

$$A = \bigoplus_n \text{Hom}_{\mathcal{DM}}(\bigoplus_L k[L], \bigoplus_L k[L](n)[n])$$

(0.2)

between the Artin–Tate objects $k[L](i)$ with $K \subset L \subset M$.

Moreover, for any fields $K \subset M$ of characteristic prime to $m$, the exact category $\mathcal{M}$ of mixed Artin–Tate motives with coefficients $k = \mathbb{Z}/m$ over $K$ is equivalent to the category $\mathcal{F}$ of filtered discrete modules $G_K$-modules $(N, F)$ over $\mathbb{Z}/m$ such that for any $i \in \mathbb{Z}$ the $G_K$-module $F^i N/F^{i+1} N$ is isomorphic to a finite direct sum of $G_K$-modules induced from the cyclotomic modules $\mu_{m^i}$ over open subgroups of $G_K$ containing $G_M$. Assuming the main conjecture, this provides a description of the triangulated subcategory of $\mathcal{DM}(K, k)$ generated by $k[L](i)$ as the bounded derived category of the exact category $\mathcal{F}$ of filtered $G_K$-modules.

0.13. To end, let us say a few words about the Koszulity condition that appears in connection with the Artin–Tate motives with finite coefficients. The theory of Koszul algebras as developed in [42], [6] applies to graded algebras $A = \bigoplus_{n \geq 0} A_n$ such that $A_0$ is a semi-simple algebra. It is not difficult to generalize it to non-negatively graded rings $A$ with an arbitrary base ring $A_0$, assuming that $A$ is a flat left or right graded $A_0$-module [38]. However, the graded algebra (0.2) we are interested in does not satisfy the latter assumption.

It turns out that the Koszul property, just as the property of a nonnegatively graded ring to be quadratic, does not depend on the base ring in the zero-degree component. For the graded algebra $A$ from (0.2), one can simply replace the component $A_0$ with $A'_0 = \mathbb{Z}/m$ in order to define $A$ to be Koszul if the graded ring

$$A' = A'_0 \oplus A_1 \oplus A_2 \oplus \cdots$$

is Koszul in the sense of [42] (if $m$ is a prime number) or in the sense of [38] (in the general case). Such is the contribution that this paper makes to the general theory of Koszul rings.

0.14. After a more than a decade-long effort, V. Voevodsky, in collaboration with M. Rost and others, have recently finished their work on a complete proof of the Milnor–Bloch–Kato conjecture [50], [51]. Their approach is entirely different from the one suggested in [42]; instead, it builds upon the ideas and techniques of A. Merkurjev and A. Suslin’s proofs [28], [29] in degrees 2 and 3. A simplified, elementary exposition of the easy first step of their argument can be found in the present author’s paper [37].
Our Koszulity conjectures remain wide open.

0.15. The fairly simple homological formalism describing the situations 0.10 (i–ii) for Tate motives with coefficients in a field $k$ is presented in Section 1. An almost equally simple situation 0.10 (iii) for Tate motives with coefficients in a finite field $k$ is partly treated in Section 2 using the filtered bar construction.

We pass to the full generality starting from Section 3, where we describe the exact subcategory of mixed objects in a triangulated category with the Hom groups given by Beilinson–Lichtenbaum formulas. The construction of the associated graded category to a filtered exact category with a twist functor and related natural transformation is presented in Section 4. The restriction-of-base construction underlying the claim that the Koszul property does not depend on the base ring is introduced in Section 5. These three sections form the technical heart of the paper.

We prove that the diagonal cohomology ring is quadratic, and any quadratic ring can be realized as the diagonal cohomology, in Section 6. The Koszul property of (big) graded rings in the general and the flat cases is studied in Section 7. We digress to apply our techniques in order to generalize the results of [42] and [36, Section 5] in Section 8. In particular, we obtain a Koszulity-based sufficient condition for existence of silly filtrations with respect to an exact subcategory of a triangulated category. The proofs of main results are finished and the conclusions discussed in Section 9. In particular, the silly filtration conjecture for Artin–Tate motives is formulated, and some remarks about Tate motives with integral coefficients are included.

The purpose of Appendix A is to supply preliminary material on exact categories complementary to the standard expositions. It covers big graded rings, saturated-ness conditions, various axioms and examples of exact categories, two canonical embeddings to abelian categories, the derived categories of exact categories, the Yoneda Ext, and exact subcategories of triangulated categories. The formalism of silly filtrations is presented in Appendix B, and the K($\pi$, 1)-conjecture of Bloch and Kriz is discussed in Appendix C. It is explained why these are two equivalent formulations of the same conjecture; both the rational and the finite coefficients are considered. The realization functor to a (filtered) triangulated category from the derived category of its exact subcategory is constructed in Appendix D.

Acknowledgements. The author is grateful to V. Voevodsky and A. Beilinson for posing the problem and for numerous very helpful conversations. I would like also to thank P. Deligne, S. Bloch, V. Retakh, A. Goncharov, D. Orlov, A. Vishik, A. Polishchuk, V. Vologodsky, and M. Bondarko for very helpful discussions.

This work was started when the author was visiting the Mathematics Department of Harvard University on the invitation of D. Kazhdan in the Fall of 1994, and most of it has been done when I was a graduate student at the same university in the subsequent years. I am glad to use this opportunity to thank Harvard for its hospitality. These results were presented at the Fall 1999 conference in Oberwolfah, and I want to thank the MFO and the organizers of the conference for the invitation.
1. Toy Example I: Strictly Exceptional Sequence

1.1. Existence of t-structure. Let $\mathcal{D}$ be a triangulated category generated by a sequence of objects $E_i \in \mathcal{D}, \ i \in \mathbb{Z}$ satisfying the following conditions

\[
\begin{align*}
\text{Hom}_\mathcal{D}(E_i, E_j[n]) &= 0 \quad \text{for all } i > j \text{ and } n \in \mathbb{Z}; \\
\text{Hom}_\mathcal{D}(E_i, E_i) &= \text{a division ring for all } i \in \mathbb{Z}.
\end{align*}
\]

(1.1)

Let $\mathcal{A}$ be the minimal full subcategory of $\mathcal{D}$ containing the objects $E_i$ and closed under extensions (see [4, 1.2.6] or Section A.8 for the definition). The following result is a generalization of a theorem of M. Levine [26] (see also [5]) inspired by R. Bezrukavnikov’s paper [9].

**Theorem 1.1.** The subcategory $\mathcal{A}$ is the heart of a (necessarily bounded) $t$-structure on $\mathcal{D}$ if and only if $\text{Hom}_\mathcal{D}(E_i, E_j[n]) = 0$ for all $i, j \in \mathbb{Z}$ and $n < 0$ and $\text{Hom}_\mathcal{D}(E_i, E_j) = 0$ for all $i \neq j$.

**Proof.** "If": let $\mathcal{E}$ denote the full subcategory of $\mathcal{D}$ consisting of direct sums of objects $E_i$. Clearly, $\mathcal{E}$ is a semisimple abelian category and one has $\text{Hom}_\mathcal{D}(X, Y[n]) = 0$ for $n < 0$ and $X, Y \in \mathcal{E}$. It follows that $\mathcal{E}$ is an admissible abelian subcategory of $\mathcal{D}$ in the sense of [4, Section 1.2], hence by [4, Sections 1.3.13–14] the subcategory $\mathcal{A}$ is the heart of a bounded $t$-structure on $\mathcal{D}$. The reader can find some additional details in [9, Lemma 3].

"Only if": the condition of vanishing of $\text{Hom}_\mathcal{D}(X, Y[n])$ for $n < 0$ and $X, Y \in \mathcal{A}$ follows immediately from the definitions of a $t$-structure and its heart. Now let $f: E_i \to E_j$ be a morphism of degree 0. By the conditions (1.1), $f = 0$ if $i > j$, so it remains to consider the case $i < j$.

Let $C$ denote the cone of the morphism $f$. By [4, Théorème 1.3.6], there exists a distinguished triangle $X[1] \to C \to Y \to X[2]$ with $X, Y \in \mathcal{A}$. Let $\mathcal{D}_i$ denote the full triangulated subcategory of $\mathcal{D}$ generated by the object $E_i$. It follows easily from (1.1) that there is a triangulated functor of "successive quotients" from $\mathcal{D}$ to the Cartesian product of the triangulated subcategories $\mathcal{D}_i \subset \mathcal{D}$ sending $E_i \in \mathcal{D}$ to $(\ldots, 0, E_i, 0, \ldots) \in \prod_i \mathcal{D}_i$ (see [11, Sections 1 and 4] or [5, Lemma 1.3.2]). Applying this functor to the above triangle, one can see that $X$ is naturally isomorphic to $E_i$ and $Y$ is isomorphic to $E_j$ in $\mathcal{D}$. The compositions $E_j \to C \to E_j$ and $E_i[1] \to C \to E_i[1]$ are the identity morphisms, hence $f = 0$. □

**Remark 1.2.** One cannot move the second condition in (1.1) from the list of premises of Theorem 1.1 to the list of conditions in the right-hand side of the equivalence. Indeed, there exists a triangulated category $\mathcal{D}$ generated by a single object $E = E_0$ with $\text{Hom}_\mathcal{D}(E, E[n]) = 0$ for $n \neq 0$ such that the full subcategory $\mathcal{A} \subset \mathcal{D}$ whose only objects are $E$ and 0 is the heart of a bounded $t$-structure on $\mathcal{D}$, and $\text{Hom}_\mathcal{D}(E, E)$ is not a division ring. One simply takes $\mathcal{A}$ to be the quotient category of the category of not more than countably dimensional vector spaces over a field $k$ by the Serre subcategory of finite-dimensional vector spaces, and $\mathcal{D} = \mathcal{D}^b(\mathcal{A})$. 
1.2. Diagonal cohomology and Koszulity. Let $k$ be a field and $\mathcal{D}$ be a $k$-linear triangulated category generated by a sequence of objects $E_i \in \mathcal{D}$, $i \in \mathbb{Z}$, satisfying the conditions

\[
\text{Hom}_\mathcal{D}(E_i, E_j[n]) = 0 \quad \text{for all } i > j \text{ and } n \in \mathbb{Z}; \\
\text{Hom}_\mathcal{D}(E_i, E_i[n]) = 0 \quad \text{for all } i \in \mathbb{Z} \text{ and } n \neq 0; \\
\text{Hom}_\mathcal{D}(E_i, E_i) = k \quad \text{for all } i \in \mathbb{Z}.
\]

Furthermore, assume that $E_i \in \mathcal{D}$ satisfy the equivalent conditions of Theorem 1.1. In addition, suppose that a triangulated autoequivalence of the category $\mathcal{D}$, denoted by $X \mapsto X(1)$, is given together with isomorphisms $E_i(1) \simeq E_{i+1}$. The functor $X \mapsto X(1)$ will be called the twist functor and its integral powers will be denoted by $X \mapsto X(j)$, $j \in \mathbb{Z}$.

Since $\mathcal{A}$ is the heart of a $t$-structure on $\mathcal{D}$, there are natural maps $\text{Ext}^n_\mathcal{A}(X, Y) \to \text{Hom}_\mathcal{D}(X, Y[n])$ for all $X, Y \in \mathcal{A}$ and $n \geq 0$, where $\text{Ext}^n_\mathcal{A}$ denotes the Yoneda Ext in the abelian category $\mathcal{A}$ (see Section A.8, or [26], or [5, Section 4.0]). These maps are compatible with the multiplicative structure on $\text{Ext}^n_\mathcal{A}$ and $\text{Hom}_\mathcal{D}$. Besides, they are always isomorphisms for $n = 1$ and monomorphisms for $n = 2$ [4, Remark 3.1.17]. We will be interested in the question when all these maps are isomorphisms.

The results below in this section are essentially due to A. Beilinson, V. Ginzburg, and V. Schechtman [5].

Recall that a graded algebra $A = A_0 \oplus A_1 \oplus A_2 \oplus \cdots$ over a field $k$ with $A_0 = k$ is called quadratic [42] if it is multiplicatively generated by $A_1$ with relations in degree 2.

Proposition 1.3. (1) For the above abelian category $\mathcal{A}$, one has $\text{Ext}^n_\mathcal{A}(E_i, E_j) = 0$ for $n > j - i$.

(2) The graded algebra $A$ with the components $A_n = \text{Ext}^n_\mathcal{A}(E_0, E_n)$ (and the multiplication defined in terms of the Yoneda multiplication on the Ext using the twist functor $X \mapsto X(1)$ on the category $\mathcal{A}$) is quadratic.

(3) For any quadratic graded algebra $A$ over $k$ there exists a $k$-linear abelian category $\mathcal{A}$ with a sequence of objects $E_i \in \mathcal{A}$ and a twist functor $X \mapsto X(1)$ on $\mathcal{A}$ such that $E_i(1) \simeq E_{i+1}$, all the objects of $\mathcal{A}$ can be obtained from $E_i$ as iterated extensions, the derived category $\mathcal{D} = \mathcal{D}^b(\mathcal{A})$ with the objects $E_i \in \mathcal{D}$ satisfies the conditions (1.2) and the diagonal Ext algebra $\bigoplus_n \text{Ext}^n_\mathcal{A}(E_0, E_n)$ is isomorphic to the graded algebra $A$.

(4) Moreover, for any quadratic algebra $A$ there exists a unique, up to a unique exact equivalence, preserving $E_i$ and the twist functor, abelian category $\mathcal{A}$ in (3) such that $\text{Ext}^n_\mathcal{A}(E_i, E_j) = 0$ for all $n \neq j - i$, $n = 1$ or 2.

Proof. Under the conditions (1.2), the functor of “successive quotients” mentioned in the proof of Theorem 1.1 becomes simply a triangulated functor from $\mathcal{D}$ to the bounded derived category of finite-dimensional graded $k$-vector spaces sending $E_i$ to the vector space $k$ placed in the cohomological degree 0 and the grading $i$. Restricting this functor to the category $\mathcal{A}$, one obtains an exact faithful functor from $\mathcal{A}$ to the category of finite-dimensional graded $k$-vector spaces transforming the twist to the shift of grading. According to [16, Proposition 2.14], one can identify $\mathcal{A}$ with the category of finite-dimensional graded left comodules over a
graded coalgebra \( C \) over \( k \) so that the object \( E_i \) corresponds to a one-dimensional comodule \( k \) placed in degree \( i \). Besides, \( \mathcal{A} \) is a mixed category in the sense of [7, Section 2.1.2], the indices of the increasing filtration in [7] being minus the indices \( i \) of the objects \( E_i \). It follows that \( C \) is nonpositively graded with \( C_0 = k \). An explicit construction of the coalgebra \( C \) can be found in [7, Section 2.1.7].

Since any \( \text{C-comodule} \) is a union of its finite-dimensional subcomodules, the spaces \( \text{Ext}^n(A, E_i) \) can be computed as the bigrading pieces of the reduced cobar-complex [42, Proposition 3, Theorem 1.4]. To verify uniqueness in (4), notice that in the assumptions of (4) the coalgebra \( C \) is quadratic by [42, Proposition 1], so it is uniquely determined by its quadratic dual algebra \( A \).

To prove existence in (3) and (4), it suffices to set \( A \) to be the category of finite-dimensional graded \( C \)-comodules.

Consequently, if the natural maps \( \text{Ext}^n_{\mathcal{A}}(X, Y) \to \text{Hom}_{\mathcal{D}}(X, Y[n]) \) are isomorphisms for all \( X,Y \in \mathcal{A} \) and \( n \geq 0 \), then \( \text{Hom}_{\mathcal{D}}(E_i, E_j[n]) = 0 \) for \( n > j - i \) and the graded algebra \( A \) with the components \( A_n = \text{Hom}_{\mathcal{D}}(E_0, E_n[n]) \) is quadratic. Conversely, any quadratic algebra \( A \) can be realized in this way.

**Theorem 1.4.** Assume that \( \text{Hom}_{\mathcal{D}}(E_i, E_j[n]) = 0 \) for \( n \neq j - i \). Then the maps \( \text{Ext}^n_{\mathcal{A}}(X, Y) \to \text{Hom}_{\mathcal{D}}(X, Y[n]) \) are isomorphisms for all \( X,Y \in \mathcal{A} \) and all \( n \geq 0 \) if and only if the graded algebra \( A \) is Koszul (see [42] for the definition).

**Proof.** As it was explained in the proof of Proposition 1.3, the spaces \( \text{Ext}^n_{\mathcal{A}}(E_0, E_i) \) are isomorphic to the bigraded pieces of the cohomology of a nonpositively graded coalgebra \( C \). Now if \( \text{Ext}^n_{\mathcal{A}}(E_0, E_i) = 0 \) for \( n \neq i \), then the coalgebra \( C \) is Koszul, so by [42, Proposition 3], the algebra \( A \) is Koszul, too. This proves the “only if” part.

“If”: since the maps \( \text{Ext}^n_{\mathcal{A}}(X, Y) \to \text{Hom}_{\mathcal{D}}(X, Y[n]) \) are injective for \( n \leq 2 \), one has \( \text{Ext}^n_{\mathcal{A}}(E_0, E_i) = 0 \) for \( n \neq i \) and \( n = 1 \) or 2, so the coalgebra \( C \) is quadratic.

Since these maps are also bijective for \( n = 1 \), the morphism of graded algebras \( \bigoplus_{n} \text{Ext}^n_{\mathcal{A}}(E_0, E_n) \to A \) is an isomorphism in degree 1 and a monomorphisms in degree 2. If the algebra \( A \) is quadratic, it follows from part (2) of Proposition 1.3 that this morphism is an isomorphism. Consequently, the algebra \( A \) is quadratic dual to the coalgebra \( C \), and if \( A \) is Koszul, then \( C \) is Koszul, too. Therefore, the morphisms \( \text{Ext}^n_{\mathcal{A}}(E_i, E_j) \to \text{Hom}_{\mathcal{D}}(E_i, E_j[n]) \) are isomorphisms for all \( i, j \), and \( n \). Since all the objects of \( \mathcal{A} \) are successive extensions of the objects \( E_i \), we are done.

**Remark 1.5.** One can drop the condition that \( \mathcal{D} \) be linear over a field in Proposition 1.3 and Theorem 1.4, replacing the condition \( \text{Hom}_{\mathcal{D}}(E_i, E_i) = k \) with the condition that \( \text{Hom}_{\mathcal{D}}(E_i, E_i) \) be a division ring, as in Section 1.1. An even greater generality of arbitrary base ring is achieved in Sections 6–7 by replacing abelian hearts with exact subcategories.
2. Toy Example II: Conilpotent Coalgebra

Let $C$ be a coalgebra over a field $k$ and $k \to C$ be a coaugmentation of $C$ (i.e., a morphism of coalgebras). Recall [42, Section 3.1] that the coaugmentation filtration on $C$ is an increasing filtration defined by the rule

$$F_n C = \text{Ker}(C \to C^\otimes n \to (C/k)^{\otimes n+1}),$$

where $C \to C^\otimes n$ is the iterated comultiplication map and the map $(C/k)^{\otimes n+1}$ is induced by the cokernel $C \to C/k$ of the coaugmentation morphism. The coalgebra $C$ is called conilpotent if the filtration $F$ is exhaustive, i.e., $C = \bigcup_n F_n C$. For any coaugmented coalgebra $C$, the subcoalgebra $\text{Nilp} C = \bigcup_n F_n C \subset C$ is the maximal conilpotent subcoalgebra of $C$.

The coaugmentation morphism endows any vector space over $k$ with a structure of $C$-comodule, called the trivial $C$-comodule structure. A finite-dimensional $C$-comodule is a comodule over $\text{Nilp} C$ if and only if it is a successive extension of copies of the trivial comodule $k$ over $C$.

Set $F^{-i} C = F_i C$. Consider the category $\mathcal{F}$ of finite-dimensional left $C$-comodules $N$ endowed with a decreasing filtration $F$ compatible with the filtration $F$ on $C$. This is equivalent to the filtration $F$ on $N$ being a filtration by $C$-subcomodules such that all the quotient $C$-comodules $F^i N/F^{i+1} N$ have trivial $C$-comodule structures. We also assume that $F^i N = N$ for $i \ll 0$ and $F^i N = 0$ for $i \gg 0$. The category $\mathcal{F}$ has a natural exact category structure in which a short sequence $0 \to N' \to N \to N'' \to 0$ is exact if and only if the sequence of associated graded vector spaces $0 \to \text{gr}_F N' \to \text{gr}_F N \to \text{gr}_F N'' \to 0$ is exact (cf. Section A.5(5)). Notice that the category $\mathcal{F}$ only depends on the subcoalgebra $\text{Nilp} C \subset C$.

Let $\mathcal{E}$ denote the abelian category of finite-dimensional left $C$-comodules; then there is an exact forgetful functor $\mathcal{F} \to \mathcal{E}$. There is a twist functor $X \mapsto X(1)$ on the category $\mathcal{F}$ defined by the rule $F^i X(1) = F^{i-1} X$. For any object $X \in \mathcal{F}$ there is a natural morphism $X \to X(1)$ that is transformed to the identity endomorphism by the forgetful functor $\mathcal{F} \to \mathcal{E}$. Denote by $E_i \in \mathcal{F}$ the one-dimensional trivial $C$-comodule $k$ placed in the filtration component $i$. Then $E_{i+1} = E_i(1)$ and there are natural morphisms $E_i \to E_{i+1}$ for all $i \in \mathbb{Z}$ corresponding to the identity morphism $k \to k$. Let $H(C) = \bigoplus_n H^n(C)$ be the cohomology algebra of the coaugmented coalgebra $C$ (see [42, Section 1.1]) and $\mathcal{D} = \mathcal{D}^b(\mathcal{F})$ be the bounded derived category of $\mathcal{F}$ (see Section A.7 or [31]).

**Theorem 2.1.**

1. The objects $E_i \in \mathcal{D}$ satisfy the conditions (1.2).

2. One has $\text{Ext}^n_F(E_i, E_j) = 0$ for $n > j - i$. The graded $k$-algebra $A$ with the components $A_n = \text{Ext}^n_F(E_0, E_n)$ is quadratic and isomorphic to the “quadratic part” of $H(C)$ of the graded algebra $H(C)$ (see [42, Section 2.1] for the definition).

3. The morphisms $\text{Ext}^n_F(E_i, E_j) \to H^n(C)$ induced by the functor $\mathcal{F} \to \mathcal{E}$ are isomorphisms for all $n \leq j - i$ if and only if the graded $k$-algebra $H(C)$ is Koszul.

**Proof.** Let $\mathcal{F}'$ be the category of (possibly infinite-dimensional) filtered $C$-comodules $(N, F)$ such that $F^i N = 0$ for $i \gg 0$ and $N = \bigcup_i F^i N$. The filtration $F$
on $N$ is assumed to be compatible with the filtration $F$ on $C$, so the successive quotients $F^nN/F^{n+1}N$ have trivial $C$-comodule structures. Then the embedding functor $\mathcal{F} \to \mathcal{F}'$ induces isomorphisms on the Ext spaces. Indeed, for any objects $X \in \mathcal{F}$ and $Y \in \mathcal{F}'$ and an admissible epimorphism $Y \to X$ there exists an object $Z \in \mathcal{F}$ and a morphism $Z \to Y$ such that the composition $X \to Y \to Z$ is an admissible epimorphism. The same applies to the embedding of the abelian category $\mathcal{E}$ to the category $\mathcal{E}'$ of all $C$-comodules.

For any filtered vector space $V$ over $k$ the $C$-comodule $C \otimes_k V$ with its filtration $F$ induced by the filtration $\mathcal{F}$ is isomorphic to the space of filtration-preserving $F$-linear maps $V \to k$, since the associated graded $\mathcal{E}$ is exact. Computing the Ext spaces in $\mathcal{F}$ in terms of this resolution, we obtain the isomorphisms

$$\text{Ext}^n_{\mathcal{F}}(E_i, E_j) = H^n(F^{i-j}B^\bullet),$$

where $B^\bullet = \text{Hom}_C(k, \tilde{B}^\bullet)$ is the cobar-complex

$$k \to C_+ \to C_+ \otimes_k C_+ \to C_+ \otimes_k C_+ \otimes_k C_+ \to \cdots$$

with its induced filtration $F$. Similarly, $\text{Ext}^n_{\mathcal{F}}(k, k) = H^n(B^\bullet)$.

This immediately proves part (1) and the first assertion of (2). Besides, one can easily see that the algebra $A$ is quadratic dual to the quadratic part of the graded coalgebra $\text{gr}_F C$ (cf. [42, Proposition 2]). It is isomorphic to $\text{qu}_n H(C)$ by [36, Lemma 5.1] and [42, proof of main theorem]. So it remains to prove part (3).

“Only if”: If $H^n(F^{-i}B^\bullet) = H^n(B^\bullet)$ for all $n \leq i$, then the quotient complex $F^{-n}B^\bullet/F^{-n+1}B^\bullet$ has no cohomology except in degree $n$. But the associated graded complex $\text{gr}_F B^\bullet$ is isomorphic to the cobar-complex of the graded coalgebra $\text{gr}_F C$. If the latter has no cohomology outside of the diagonal $n = i$, then the graded coalgebra $\text{gr}_F C$ is Koszul and consequently the quadratic dual algebra $A$ is Koszul, too.

“If”: If the algebra $H(C)$ is Koszul, then $H(\text{Nilp} C) \cong H(C)$ [36, Corollary 5.3] and the graded coalgebra $\text{gr}_F C$ is Koszul [42, proof of main theorem]. Thus $H^n(F^{-i+1}B^\bullet) = H^n(F^{-i}B^\bullet)$ for all $n < i$. It follows by passing to the inductive limit in $i$ that $H^n(F^{-i}B^\bullet) = H^n(\text{Nilp} C)$ for all $n \leq i$. □

Remark 2.2. Instead of using the results of [42, main theorem and its proof] and [36, Section 5] in the above argument, one can reprove and generalize these results using the methods developed in this paper, and particularly in Section 4. See Section 8.
3. Filtered Exact Subcategory

Let $\mathcal{D}$ be a triangulated category and $\mathcal{E}_i \subset \mathcal{D}$, $i \in \mathbb{Z}$ be full subcategories, closed under extensions and such that

$$\text{Hom}_\mathcal{D}(X, Y[n]) = 0 \text{ for all } X \in \mathcal{E}_i, Y \in \mathcal{E}_j, \ i, j \in \mathbb{Z} \quad \text{and} \quad n = -1, \ \text{or} \ i > j \quad \text{and} \ n = 0 \text{ or } 1. \quad (3.1)$$

Let $\mathcal{E}$ be an exact category and $\Phi: \mathcal{D} \to \mathcal{D}(\mathcal{E})$ be a triangulated functor mapping $\mathcal{E}_i$ into $\mathcal{E}$. Assume that

the induced morphisms $\text{Hom}_\mathcal{D}(X, Y[n]) \to \text{Ext}_\mathcal{E}^n(X, Y)$ are isomorphisms for all $X \in \mathcal{E}_i, Y \in \mathcal{E}_j, i < j$, and $n = 0$ or 1, (3.2)

and monomorphisms for $i + 2 \leq j$ and $n = 2$.

Let $\mathcal{M}$ be the minimal full subcategory of $\mathcal{D}$, containing all $\mathcal{E}_i$ and closed under extensions. Then both $\mathcal{E}_i$ and $\mathcal{M}$ have natural exact category structures (see [18] or Section A.8) and the functors $\Phi: \mathcal{E}_i \to \mathcal{E}$ are exact.

Let $\mathcal{F}$ be the category whose objects are triples $(N, Q, \rho)$, where $N = (N, F)$ is a finitely filtered object of $\mathcal{E}$, $Q = (Q_i)$ is a finitely supported object of the Cartesian product of $\mathcal{E}_i$, and $\rho: \text{gr}_F N \to \Phi(Q)$ is an isomorphism. Here a “finitely filtered object” $(N, F)$ is a sequence

$$\cdots \longleftarrow F^{i-1}N \longleftarrow F^iN \longleftarrow F^{i+1}N \longleftarrow \cdots$$

of objects of $\mathcal{E}$ and admissible monomorphisms between them such that $F^iN = 0$ for $i \gg 0$ and $F^{i+1}N \to F^iN$ is an isomorphism for $i \ll 0$. The (stabilizing) inductive limit of $F^iN$ as $i \to -\infty$ is denoted by $N$. The object $\text{gr}_F N$ is the collection of objects $F^iN/F^{i+1}N \in \mathcal{E}$. A “finitely supported object” $(Q_i)$ is a collection of objects $Q_i \in \mathcal{E}_i$ such that $Q_i = 0$ for all but a finite number of indices $i$. The object $\Phi(Q)$ is the collection of objects $\Phi(Q_i) \in \mathcal{E}$.

The category $\mathcal{F}$ has a natural exact category structure in which a short sequence with a zero composition is exact if the related sequence of graded objects $Q = (Q_i)$ is exact in the Cartesian product of $\mathcal{E}_i$, i.e., exact in each $i$ (cf. Sections A.5(4–5)). The exact category $\mathcal{E}_i$ is equivalent to the full exact subcategory of $\mathcal{F}$ consisting of all the triples $(N, Q, \rho)$ such that $Q_j = 0$ for all $j \neq i$.

**Theorem 3.1.** (1) In the above situation, the exact categories $\mathcal{M}$ and $\mathcal{F}$ are naturally equivalent.

(2) Conversely, given any exact categories $\mathcal{E}$ and $\mathcal{E}_i$ and exact functors $\Phi_i: \mathcal{E}_i \to \mathcal{E}$, construct the exact category $\mathcal{F}$ by the above procedure. Set $\mathcal{D} = \mathcal{D}(\mathcal{F})$. Then the subcategories $\mathcal{E}_i \subset \mathcal{F} \subset \mathcal{D}$ and the functor $\Phi: \mathcal{D} \to \mathcal{D}(\mathcal{E})$ induced by the forgetful functor $\mathcal{F} \to \mathcal{E}$ satisfy the conditions (3.1–3.2). Moreover, the second assertion of (3.2) holds for all $i < j$ and $n = 2$.

3.1. Proof of part (1). Since the natural morphisms

$$\text{Hom}_{\mathcal{M}}^n(X, Y) \to \text{Hom}_{\mathcal{D}}(X, Y[n]), \quad X, Y \in \mathcal{M}, \ n \geq 0$$

(see Section A.8) are isomorphisms for $n = 0$ or 1, by (3.1) one has $\text{Ext}_{\mathcal{M}}^1(X, Y) = 0$ for $X \in \mathcal{E}_i, Y \in \mathcal{E}_j, i > j$, and $n = 0$ or 1. Using associativity of extensions in exact categories (associativity of the “$*$-operation”; cf. [4, Lemma 1.3.10] where this is done for triangulated categories), one can deduce from this vanishing of $\text{Ext}^1$ that
any object of \( \mathcal{M} \) has a finite decreasing filtration with successive quotients in \( \mathcal{E}_i \). It follows from the vanishing of \( \text{Ext}^0 \) that such filtrations are unique and preserved by all the morphisms in \( \mathcal{M} \). One can also see that a short sequence with zero composition in \( \mathcal{F} \) is exact if and only if its short sequence of successive quotients is exact in the Cartesian product of \( \mathcal{E}_i \).

Applying the functor \( \Phi \) to the above filtration on an object of \( \mathcal{M} \), one obtains a filtered object of \( \mathcal{E} \). This defines the desired functor \( \mathcal{M} \to \mathcal{F} \). To prove that it is an equivalence of exact categories, one can use the following lemma.

**Lemma 3.2.** Let \( \Lambda: \mathcal{A} \to \mathcal{B} \) be an exact functor between exact categories and \( \mathcal{C} \subset \mathcal{A} \) be a class of objects such that every object of \( \mathcal{A} \) can be obtained from objects of \( \mathcal{C} \) by successive extensions and every object of \( \mathcal{B} \) can be obtained from objects of \( \Lambda(\mathcal{C}) \) in the same way. Then if the maps \( \text{Ext}^n_{\mathcal{A}}(X, Y) \to \text{Ext}^n_{\mathcal{B}}(\Lambda(X), \Lambda(Y)) \) are isomorphisms for all \( X, Y \in \mathcal{C} \) and \( n = 0 \) or \( 1 \) and monomorphisms for all \( X, Y \in \mathcal{C} \) and \( n = 2 \), then the functor \( \Lambda \) is an equivalence of exact categories.

**Proof.** Using the five-lemma and induction on the number of subquotients in an iterated extension, one can show that the functor \( \Lambda \) induces isomorphisms on \( \text{Ext}^n \) for \( n = 0 \) and \( 1 \). This implies the assertion of the lemma. \( \square \)

Let us check that the conditions of the lemma are satisfied for the functor \( \mathcal{M} \to \mathcal{F} \) and the class of objects \( \mathcal{C} = \bigcup \mathcal{E}_i \). Let \( X \in \mathcal{E}_i \) and \( Y \in \mathcal{E}_j \). For \( i > j \), one has \( \text{Ext}^n_{\mathcal{M}}(X, Y) = 0 = \text{Ext}^n_{\mathcal{F}}(X, Y) \) for any \( n \), because the natural decreasing filtrations on objects of \( \mathcal{M} \) and \( \mathcal{F} \) split any such extensions. For \( i = j \), one has \( \text{Ext}^n_{\mathcal{M}}(X, Y) = \text{Ext}^n_{\mathcal{F}}(X, Y) = \text{Ext}^n_{\mathcal{F}}(X, Y) \) for any \( n \), due to the same natural filtrations.

It remains to consider the case \( i < j \). For \( n = 0 \) or \( 1 \), by Section A.8 and (3.2) the natural maps \( \text{Ext}^n_{\mathcal{M}}(X, Y) \to \text{Hom}_D(X, Y[n]) \to \text{Ext}^n_{\mathcal{F}}(X, Y) \) are isomorphisms. It is straightforward to check that the natural maps \( \text{Ext}^n_{\mathcal{F}}(X, Y) \to \text{Ext}^n_{\mathcal{F}}(X, Y) \) are isomorphisms, too. For \( n = 0 \), this is so because any morphism \( \Phi(X) \to \Phi(Y) \) in \( \mathcal{E} \) is compatible with the filtrations on \( \Phi(X) \) and \( \Phi(Y) \), while any morphism between \( X \) and \( Y \) considered as objects of the Cartesian product of \( \mathcal{E}_i \) is zero. For \( n = 1 \), it suffices to say that any extension of \( \Phi(X) \) and \( \Phi(Y) \) in \( \mathcal{E} \) determines an object of \( \mathcal{F} \), which becomes an extension of \( X \) and \( Y \) in \( \mathcal{F} \).

It follows from what we have proven so far that the full exact subcategories consisting of extensions of objects from \( \mathcal{E}_i \) and \( \mathcal{E}_{i+1} \) in \( \mathcal{M} \) and \( \mathcal{F} \) are equivalent for any \( i \). Indeed, bijectivity on \( \text{Ext}^0 \) and injectivity on \( \text{Ext}^1 \) between the generating objects suffice to conclude that the functor is fully faithful (see the proof of Lemma 3.2), and then surjectivity on \( \text{Ext}^1(X, Y) \) for \( X \in \mathcal{E}_i, Y \in \mathcal{E}_{i+1} \) implies surjectivity of the functor on the objects. The exact category structures on the two categories are the same, since in each of them a triple with zero composition is exact if and only if its triple of successive quotients is exact in \( \mathcal{E}_i \times \mathcal{E}_{i+1} \). Consequently, the map \( \text{Ext}^1_{\mathcal{M}}(X, Y) \to \text{Ext}^1_{\mathcal{F}}(X, Y) \) is an isomorphism for \( i+1 = j \).

Finally, for \( i + 2 \leq j \) by virtue of Section A.8 and (3.2) the natural maps \( \text{Ext}^2_{\mathcal{M}}(X, Y) \to \text{Hom}_D(X, Y[2]) \to \text{Ext}^2_{\mathcal{F}}(X, Y) \) are monomorphisms and they form a commutative square with the maps \( \text{Ext}^2_{\mathcal{M}}(X, Y) \to \text{Ext}^2_{\mathcal{F}}(X, Y) \to \text{Ext}^2_{\mathcal{F}}(X, Y) \), hence the map \( \text{Ext}^2_{\mathcal{M}}(X, Y) \to \text{Ext}^2_{\mathcal{F}}(X, Y) \) is a monomorphism.
3.2. Proof of part (2). We have already explained why \( \text{Ext}^2_{\mathcal{F}}(X, Y) = 0 \) for all \( i > j \) and \( n \geq 0 \) and why \( \text{Ext}^2_{\mathcal{F}}(X, Y) \simeq \text{Ext}^2_{\mathcal{E}}(X, Y) \) for all \( i < j \) and \( n = 0 \) or 1. Let us show that the map \( \text{Ext}^2_{\mathcal{F}}(X, Y) \to \text{Ext}^2_{\mathcal{E}}(X, Y) \) is injective for all \( i < j \).

Denote by \( \mathcal{F}_{[i,j]} \) the minimal full subcategory of \( \mathcal{F} \) containing \( \mathcal{E}_r \), \( i \leq r \leq j \), and closed under extensions. The notation \( \mathcal{F}_{(-\infty,i]} \) and \( \mathcal{F}_{[i,+\infty)} \) has the similar meaning. Any object of \( Z \in \mathcal{F} \) can be presented as an extension of an object \( Z_{\leq r} \in \mathcal{F}_{(-\infty,r]} \) and an object \( Z_{> r+1} \in \mathcal{F}_{[r+1,+\infty)} \) in a unique and functorial way.

Suppose that a class in \( \text{Ext}^2_{\mathcal{F}}(X, Y) \) is presented as the product of two classes in \( \text{Ext}^2_{\mathcal{E}}(X, Z) \) and \( \text{Ext}^2_{\mathcal{E}}(Z, Y) \). Consider the exact triple \( Z_{> r} \to Z \to Z_{\leq r-1} \). Since \( \text{Ext}^2_{\mathcal{E}}(X, Z_{\leq r-1}) = 0 \), our class in \( \text{Ext}^2_{\mathcal{F}}(X, Z) \) comes from a class in \( \text{Ext}^2_{\mathcal{E}}(X, Z_{> r}) \), so we can replace \( Z \) with \( Z_{\leq r} \). Analogously, one can replace \( Z \) with \( Z_{< r} \), so as to get \( Z \in \mathcal{F}_{[i,j]} \).

Now suppose that our class in \( \text{Ext}^2_{\mathcal{F}}(X, Y) \) is annihilated by the forgetful functor \( \Phi: \mathcal{F} \to \mathcal{E} \). Let our classes in \( \text{Ext}^2_{\mathcal{E}}(X, Z) \) and \( \text{Ext}^2_{\mathcal{E}}(Z, Y) \) be presented by exact triples \( Z \to V \to X \) and \( Y \to U \to Z \) in \( \mathcal{F} \), so our class in \( \text{Ext}^2_{\mathcal{F}}(X, Y) \) is presented by the Yoneda extension \( Y \to U \to V \to X \). So the Yoneda extension \( \Phi(Y) \longrightarrow \Phi(U) \longrightarrow \Phi(V) \longrightarrow \Phi(X) \) in \( \mathcal{E} \) is trivial. This means that the morphism \( \Phi(U) \to \Phi(V) \) can be presented as a composition \( \Phi(U) \to T \to \Phi(V) \) in such a way that the triples \( \Phi(Y) \to T \to \Phi(V) \) and \( \Phi(U) \to T \to \Phi(X) \) are exact in \( \mathcal{E} \) (see Corollary A.14).

Define a decreasing filtration on \( T \) by setting \( F^*T = T \) and \( F^rT = F^r\Phi(U) \) for all \( r > i \), where the filtration \( F \) on \( \Phi(U) \) is a part of the data constituting the object \( U \in \mathcal{F} \). The morphisms \( F^r+1T \to F^rT \) are admissible monomorphisms with the successive quotients \( T/F^{i+1}T \simeq \Phi(V)/F^{i+1}\Phi(V) \), \( F^rT/F^{r+1}T \simeq F^r\Phi(Z)/F^{r+1}\Phi(Z) \), and \( F^iT \simeq F^i\Phi(U) \). This allows to lift \( T \) to an object \( W \in \mathcal{F} \) so that the morphism \( U \to V \) factorizes as \( U \to W \to V \) and the triples \( Y \to W \to V \) and \( U \to W \to X \) are exact. Thus our class in \( \text{Ext}^2_{\mathcal{F}}(X, Y) \) vanishes.

\[ \square \]

4. Associated Graded Category

4.1. Posing the problem. Let \( \mathcal{F} \) be a small exact category endowed with a sequence of full subcategories \( \mathcal{E}_i \subset \mathcal{F}, i \in \mathbb{Z} \). Assume that each subcategory \( \mathcal{E}_i \) is closed under extensions and every object of \( \mathcal{F} \) can be obtained as a successive extension of objects from \( \mathcal{E}_i \). Moreover, assume that

\[ \text{Hom}_{\mathcal{F}}(X, Y) = 0 = \text{Ext}^1_{\mathcal{F}}(X, Y) \quad \text{for all} \quad X \in \mathcal{E}_i, Y \in \mathcal{E}_j, \text{and} \; i > j. \]  

(4.1)

Furthermore, suppose that a twist functor \( X \mapsto X(1) \) is defined on \( \mathcal{F} \) such that it is an autoequivalence of \( \mathcal{F} \) as an exact category and \( \mathcal{E}_i(1) = \mathcal{E}_{i+1} \). Finally, suppose that a natural transformation \( \sigma: X \to X(1) \) is defined for all \( X \in \mathcal{F} \) and \( \sigma_{X(1)} = \sigma_X(1) \) for all \( X \). Assume that

the induced maps \( \text{Hom}_{\mathcal{F}}(X, Y) \to \text{Hom}_{\mathcal{F}}(X, Y(r)) \) are isomorphisms for all \( X,Y \in \mathcal{E}_i, i \in \mathbb{Z}, r \geq 0. \)

(4.2)
It follows from (4.1) (see the beginning of Section 3.1) that there is an exact functor of “successive quotients” \( q = (q_i)_{i \in \mathbb{Z}}: \mathcal{F} \to \prod_i \mathcal{E}_i \). Let us require that

- any morphism \( X \to Y \) annihilated by \( q \)
- factorizes through the morphism \( \sigma_{Y(-1)}: Y(-1) \to Y \),
- or equivalently, through the morphism \( \sigma_X: X \to X(1) \).

It follows by induction on the number of subquotients in an iterated extension from (4.2) and the first equation in (4.1) that such a factorization is unique if it exists, i.e., the morphisms \( \sigma_X \) are surjective and injective (see Section A.2).

**Example 4.1.** Let \( \mathcal{E} \) and \( \mathcal{E}_i \) be exact categories and \( \Phi_0: \mathcal{E}_0 \to \mathcal{E} \) be a fully faithful exact functor (so the image of an exact triple under \( \Phi_0 \) must be an exact triple, but the converse is not required). Set \( \mathcal{E}_i = \mathcal{E}_0 \) and \( \Phi_i = \Phi_0 \) for all \( i \in \mathbb{Z} \) and consider the exact category \( \mathcal{F} \) of finitely filtered objects in \( \mathcal{E} \) with subquotients lifted to \( \mathcal{E}_i \) as constructed in Section 3. Identify each \( \mathcal{E}_i \) with the full exact subcategory of \( \mathcal{F} \) consisting of all the triples \( (N, Q, \rho) \) such that \( Q_j = 0 \) for \( j \neq i \). Let the twist functor \( X \mapsto X(1) \) on \( \mathcal{F} \) be defined by \( F^i N(1) = F^{i-1} N, Q(1)_i = Q_{i-1} \), and the morphism \( \sigma_X \) be acting by the identity on \( N \) and by zero on \( Q \). Then all the conditions (4.1–4.3) are satisfied.

In particular, given a coaugmented coalgebra \( C \) over a field \( k \) one can take \( \mathcal{E} \) to be the abelian category of left \( C \)-comodules, \( \mathcal{E}_0 \) to be the abelian category of finite-dimensional \( k \)-vector spaces, and \( \Phi_0 \) to be the functor endowing a vector space with the trivial \( C \)-comodule structure. Then the category \( \mathcal{F} \) from the above example coincides with the category \( \mathcal{F} \) from Section 2. More generally, given a coalgebra \( C \) over \( k \) endowed with an increasing filtration \( F_0 C \subset F_1 C \subset \cdots \) compatible with the comultiplication, one can consider the exact category \( \mathcal{F} \) of finite-dimensional filtered \( C \)-comodules. This category \( \mathcal{F} \) also satisfies (4.1–4.3).

Together with the latter category, one can consider the category \( \mathcal{G} \) of finite-dimensional graded comodules over the graded coalgebra \( \text{gr}_F C \). Then there will be the exact functor of associated graded comodule \( \text{gr}_F: \mathcal{F} \to \mathcal{G} \). Our goal in this section is to extend this construction to arbitrary exact categories \( \mathcal{F} \) satisfying the conditions (4.1–4.3). So we would like to assign to such a category \( \mathcal{F} \) an exact category \( \mathcal{G} \) with the following properties.

The exact category \( \mathcal{G} \) should be endowed with a sequence of full exact subcategories \( \mathcal{E}_i, \ i \in \mathbb{Z} \). Each subcategory \( \mathcal{E}_i \) should be closed under extensions and every object of \( \mathcal{G} \) should be an iterated extension of objects from \( \mathcal{E}_i \). Furthermore, one should have

\[
\begin{align*}
\text{Hom}_\mathcal{G}(X, Y) &= 0 \quad \text{for all} \ X \in \mathcal{E}_i, \ Y \in \mathcal{E}_j, \ i \neq j; \\
\text{Ext}^1_\mathcal{G}(X, Y) &= 0 \quad \text{for all} \ X \in \mathcal{E}_i, \ Y \in \mathcal{E}_j, \ i > j.
\end{align*}
\]

Finally, an autoequivalence of the exact category \( \mathcal{G} \), denoted by \( X \mapsto X(1) \), should be defined so that \( \mathcal{E}_i(1) = \mathcal{E}_{i+1} \).

The categories \( \mathcal{F} \) and \( \mathcal{G} \) should be related in the following way. There should be an exact functor \( \text{gr}: \mathcal{F} \to \mathcal{G} \) mapping each \( \mathcal{E}_i \subset \mathcal{F} \) to \( \mathcal{E}_i \subset \mathcal{G} \) and defining an equivalence between these exact categories. The functor \( \text{gr} \) should be compatible with the twist functors \( X \mapsto X(1) \) on \( \mathcal{F} \) and \( \mathcal{G} \). And most importantly, for any...
objects $X, Y \in \mathcal{F}$ there should be a functorial long exact sequence

$$\cdots \rightarrow \text{Ext}^n_{\mathcal{F}}(X, Y(-1)) \rightarrow \text{Ext}^{n+1}_{\mathcal{F}}(X, Y) \rightarrow \text{Ext}^n_{\mathcal{F}}(gr \, X, gr \, Y) \rightarrow \text{Ext}^{n+1}_{\mathcal{F}}(X, Y(-1)) \rightarrow \cdots$$ (4.5)

**Theorem 4.2.** There is a construction assigning to any small exact category $\mathcal{F}$ with the additional data satisfying (4.1–4.3) a small exact category $\mathcal{G}$ with the additional data and an exact functor $gr: \mathcal{F} \rightarrow \mathcal{G}$ satisfying (4.4–4.5).

The proof of the theorem occupies the rest of the present section.

4.2. A construction of the category $\mathcal{G}$. Consider the category $\mathcal{H}$ whose objects are diagrams of the form

$$V \rightarrow U \rightarrow V(1) \rightarrow U(1),$$

where $U, V \in \mathcal{F}$, the rightmost map is obtained by applying the twist functor $X \mapsto X(1)$ to the leftmost map, the compositions $V \rightarrow U \rightarrow V(1)$ and $U \rightarrow V(1) \rightarrow U(1)$ are equal to the morphisms $\sigma_V$ and $\sigma_U$, and the induced sequence

$$q(V) \rightarrow q(U) \rightarrow q(V(1)) \rightarrow q(U(1))$$

is exact (see Section A.7) in $\prod_i \mathcal{E}_i$.

Let $\Delta: \mathcal{H} \rightarrow \prod_i \mathcal{E}_i$ be the functor assigning to a diagram $(U, V)$ the object $\text{Im}(q(U) \rightarrow q(V(1)))$. Let $\mathcal{I}$ denote the ideal of morphisms in $\mathcal{H}$ annihilated by $\Delta$, and let $\mathcal{H}/\mathcal{I}$ be the quotient category. Let $\mathcal{S}$ be the class of morphisms in $\mathcal{H}/\mathcal{I}$ that the functor $\Delta$ sends to isomorphisms. Our first aim is to show that the class $\mathcal{S} \subset \mathcal{H}/\mathcal{I}$ is localizing (i.e., satisfies the Ore conditions). It is clear that if any two morphisms $X \Rightarrow Y$ in $\mathcal{H}/\mathcal{I}$ have equal compositions with a morphism $X' \rightarrow X$ or $Y \rightarrow Y'$ belonging to $\mathcal{S}$, then these two morphisms $X \Rightarrow Y$ are equal.

Let $(X, Y) \rightarrow (K, L) \leftarrow (U, V)$ be two morphisms in $\mathcal{H}$ such that the morphism $\Delta(U, V) \rightarrow \Delta(K, L)$ is an admissible epimorphism in $\prod_i \mathcal{E}_i$. Then the morphism $U \oplus L \rightarrow K$ is an admissible epimorphism in $\mathcal{F}$. Indeed, it suffices to check that the morphism $q(U) \oplus q(L) \rightarrow q(K)$ is an admissible epimorphism, since an extension of admissible epimorphisms is always an admissible epimorphism. Consider the fibered product $X \cap_K (U \oplus L)$ in $\mathcal{F}$ (see axiom Ex2 in Section A.3). Let the map $X \cap_K (U \oplus L) \rightarrow (Y \oplus V)(1)$ be defined as the composition $X \cap_K (U \oplus L) \rightarrow X \oplus U \rightarrow (Y \oplus V)(1)$ and the map $Y \oplus V \rightarrow X \cap_K (U \oplus L)$ be induced by the maps $Y \rightarrow X$, $V \rightarrow L$, $V \rightarrow U$, and minus the map $V \rightarrow L$. Then the diagram

$$Y \oplus V \rightarrow X \cap_K (U \oplus L) \rightarrow (Y \oplus V)(1) \rightarrow (X \cap_K (U \oplus L))(1)$$

is an object of the category $\mathcal{H}$. There are natural morphisms from this object to the objects $(X, Y)$ and $(U, V)$; the square diagram formed by these two morphisms and the morphisms $(X, Y) \rightarrow (K, L) \leftarrow (U, V)$ is commutative modulo $\mathcal{I}$. The object $\Delta(X \cap_K (U \oplus L), Y \oplus V)$ is the fibered product of $\Delta(X, Y)$ and $\Delta(U, V)$ over $\Delta(K, L)$. In particular, if the morphism $(U, V) \rightarrow (K, L)$ belongs to $\mathcal{S}$, then so does the morphism $(X \cap_K (U \oplus L), Y \oplus V) \rightarrow (X, Y)$.
This proves a half of the Ore conditions; the dual half is proved in the dual way.

**Remark 4.3.** The category of diagrams \((U, V)\) is perhaps best viewed as a DG-category, and even an exact DG-category in the sense of \([39, \text{Remark 3.5}]\); its full subcategory \(\mathcal{H}\) of all diagrams satisfying the exactness condition can be then considered as its full exact DG-subcategory. Very roughly, the natural transformation \(\sigma\) plays the role of a (central) curvature element in a (purely even) “CDG-ring” \(\mathcal{F}\). It would be interesting to know whether one can use some derived category of the second kind of this exact DG-category in order to approach the following problem. How to construct the exact quotient category \(\mathcal{G} = \mathcal{F}/\sigma\) given only a twist functor \(X \mapsto X(1)\) and a natural transformation \(\sigma: X \to X(1)\) on an exact category \(\mathcal{F}\), satisfying some reasonable conditions (e.g., that the morphisms \(\sigma_X\) be injective and surjective)?

**4.3. Exact category structure on \(\mathcal{G}\).** The category \(\mathcal{G}\) is defined as the localization \(\mathcal{G} = (\mathcal{H}/\mathcal{I})[S^{-1}]\). Set a short sequence in \(\mathcal{G}\) to be exact if its image under the functor \(\Delta\) is exact. Let us check that this defines an exact category structure on \(\mathcal{G}\).

Consider a morphism \(f\) in \(\mathcal{G}\) whose image under \(\Delta\) is an admissible epimorphism. It is clear that such a morphism is surjective in \(\mathcal{G}\). Represent \(f\) by a morphism \((U, V) \to (K, L)\) in \(\mathcal{H}\) and apply the construction from Section 4.2 to the pair of morphisms \((0, 0) \to (K, L) \leftarrow (U, V)\). We obtain a morphism \((\text{Ker}(U \oplus L \to K), V) \to (U, V)\) in \(\mathcal{H}\) whose image \(g\) in \(\mathcal{G}\) completes the morphism \(f\) to an exact triple. Let us check that the morphism \(g\) is the kernel of \(f\). Any morphism with the target \((U, V)\) in \(\mathcal{G}\) can be represented by a morphism \((S, T) \to (U, V)\) in \(\mathcal{H}\). Assume that the composition \((S, T) \to (U, V) \to (K, L)\) is annihilated by \(\Delta\). Then it follows from (4.3) that the morphism \(S \to K\) factorizes through \(L\), since the composition \(S \to K \to L(1)\) is annihilated by \(q\). This allows to lift the morphism \((X, Y) \to (U, V)\) to a morphism \((X, Y) \to (\text{Ker}(U \oplus L \to K), V)\) in \(\mathcal{H}\).

Finally, suppose that we are given an exact triple in \(\mathcal{G}\); it can be represented by a short sequence \((S, T) \to (U, V) \to (K, L)\) in \(\mathcal{H}\). Any morphism with the target \((K, L)\) in \(\mathcal{G}\) can be represented by a morphism \((X, Y) \to (K, L)\) in \(\mathcal{H}\). Applying the construction from Section 4.2 again, we obtain an object \((X \cap_K (U \oplus L), Y \oplus V)\) in \(\mathcal{H}\) together with natural morphisms from it to \((X, Y)\) and \((U, V)\). Just as above, one can construct a morphism \((S, T) \to (X \cap_K (U \oplus L), Y \oplus V)\) in \(\mathcal{H}\) and the triple \((S, T) \to (X \cap_K (U \oplus L), Y \oplus V) \to (X, Y)\) is exact in \(\mathcal{G}\). These observations together with their dual versions suffice to check that \(\mathcal{G}\) satisfies the exact category axioms Ex0–Ex3 from Section A.3.

The functor \(\text{gr}: \mathcal{F} \to \mathcal{G}\) assigns to an object \(X\) the diagram \((X, X(-1))\); it is obviously exact. The twist functor \(Z \mapsto Z(1)\) on \(\mathcal{G}\) is induced by the twist functor \((X, Y) \mapsto (X(1), Y(1))\) on \(\mathcal{H}\). The exact subcategory \(\mathcal{E}_i \subset \mathcal{G}\) consists of all objects \(Z\) such that the graded object \(\Delta(Z) \in \prod_j \mathcal{E}_j\) is concentrated in the grading \(j = i\). One can construct a filtration \((Z_{\geq i})\) on an object \(Z = (X, Y) \in \mathcal{G}\) with successive quotients in \(\mathcal{E}_i\) by the rules \(Z_{\geq i} = (X_{\geq i}, \text{Ker}(Y_{\geq i-1} \to q_{i-1}(X)))\) or, equivalently, \(Z_{\geq i} = (\text{Ker}(X_{\geq i-1} \to q_{i-2}(Y)), Y_{\geq i-1})\); see Section 3.2 for the notation \(W_{\geq i}\). Using this filtration, one can easily check that the functor \(\text{gr}\) induces equivalences between the exact subcategories \(\mathcal{E}_i\) in \(\mathcal{F}\) and \(\mathcal{G}\) and the exact category \(\mathcal{G}\) satisfies (4.4).
4.4. Two lemmas. The following lemmas will be needed in the remaining part of the proof.

**Lemma 4.4.** Let \( \Lambda: \mathcal{A} \to \mathcal{B} \) be an exact functor between exact categories such that for any admissible epimorphism \( T \to \Lambda(X) \) in \( \mathcal{A} \) there exist an admissible epimorphism \( T \to \Lambda(Z) \) in \( \mathcal{B} \) making the triangle \( \Lambda(Z) \to T \to \Lambda(X) \) commute. Let \( \xi \) be a class in \( \text{Ext}_A^n(X, Y) \) and \( \eta \) be a class in \( \text{Ext}_B^m(\Lambda(Y), W) \) such that \( \eta \Lambda(\xi) = 0 \) and \( m \geq 1 \). Then there exist a morphism \( f: Y' \to Y \) in \( \mathcal{A} \) and a class \( \xi' \in \text{Ext}_A^n(X, Y') \) such that \( \xi = f\xi' \) and \( \eta \Lambda(f) = 0 \).

**Proof.** We will be mostly interested in the case \( m = 1 \); however, in Section 5 we will also use the case \( n = 1 \). Let us start with some general remarks. By Proposition A.13, a Yoneda extension \( (B \to C_1 \to \cdots \to C_n \to A) \) in an exact category \( \mathcal{E} \) is trivial if and only if there exists a Yoneda extension \( (B \to D_1 \to \cdots \to D_n \to A) \) mapping both to the extension \( (B \to C_1 \to \cdots \to C_n \to A) \) and to the trivial extension \( (B \to B \to 0 \to \cdots \to 0 \to A \to A) \). The latter condition simply means that the admissible monomorphism \( B \to D_1 \) splits. Furthermore, one can make the morphisms \( D_i \to C_i \) admissible epimorphisms by replacing \( D_i \) with \( D_i \oplus C_i \oplus C_{i-1} \) for \( 1 < i < n \), \( D_1 \) with \( D_1 \oplus C_1 \), and \( D_n \) with \( D_n \oplus C_{n-1} \).

Now we apply these observations to the case of the Yoneda extension
\[
(W \to V_1 \to \cdots \to V_m \to \Lambda(Z_1) \to \cdots \to \Lambda(Z_n) \to \Lambda(X))
\]
obtained by composing an extension representing \( \eta \) with the image under \( \Lambda \) of an extension representing \( \xi \). An extension \( (W \to T_1 \to \cdots \to T_{m+n} \to \Lambda(X)) \) maps both to this composition and to the trivial extension, and moreover, the maps \( T_{j+m} \to \Lambda(Z_j) \) are admissible epimorphisms. Using the assumption of the lemma and decreasing induction on \( j \), one can construct admissible epimorphisms \( Z_j' \to Z_j \) forming a map of Yoneda extensions \( (Y' \to Z_1' \to \cdots \to Z_n' \to X) \to (Y \to Z_1 \to \cdots \to Z_n \to X) \) whose image under \( \Lambda \) factorizes through the map of Yoneda extensions \( (\text{Im}(T_m \to T_{m+1}) \to T_{m+1} \to \cdots \to T_{m+n} \to \Lambda(X)) \to (\Lambda(Y) \to \Lambda(Z_1) \to \cdots \to \Lambda(Z_n) \to \Lambda(X)) \). This provides the desired morphism \( f: Y' \to Y \) and class \( \xi' \in \text{Ext}^n(X, Y') \).

Notice that we have obtained slightly more than we wanted: the assertion of the lemma does not require the map \( f \) to be an admissible epimorphism. However, applying the assumption of the lemma to construct an admissible epimorphism \( Z_n' \to Z_n \) provides a way to obtain an admissible epimorphism \( Z_n' \to X \) together with a morphism \( Z_n' \to Z_n \) in the category \( \mathcal{A} \) that we really need. \( \square \)

Recall the definition of a **big graded ring** from Section A.1. The next lemma can be viewed as a module version of Corollary A.16.

**Lemma 4.5.** Let \( \Lambda: \mathcal{A} \to \mathcal{B} \) be an exact functor between small exact categories satisfying the assumptions of Lemma 4.4. Then for any object \( W \in \mathcal{B} \) the right graded module \( \text{Ext}^n_B(\Lambda(X), W)_{X \in \mathcal{A}, n \geq 0} \) over the big graded ring \( (\text{Ext}^n_B(X, Y))_{Y \in \mathcal{A}, X \in \mathcal{B}, n \geq 0} \) over the set of all objects of \( \mathcal{A} \) is induced from the right module \( \text{Hom}_B(\Lambda(Y), W)_Y \) over the big subring \( \text{Hom}_A(X, Y))_{Y \to X} \subset (\text{Ext}^n_B(X, Y))_{Y,X,n} \).

**Proof.** There is an obvious natural map
\[
(\text{Hom}_B(\Lambda(Y), W))_Y \otimes_{(\text{Hom}_A(X,Y))_{Y,X}} (\text{Ext}^n_B(X,Y))_{Y,X,n} \to (\text{Ext}^n_B(\Lambda(X), W))_{X,n}.
\]
It is surjective, since for any class $\eta \in \text{Ext}^n_\mathcal{B}(\Lambda(X), W)$ there exist a class $\xi \in \text{Ext}^n_\mathcal{A}(X, Y)$ and a morphism $g: \Lambda(Y) \to W$ in $\mathcal{B}$ such that $\eta = g\Lambda(\xi)$. One shows this using the assumption of Lemmas 4.4–4.5 in a way similar to (and simpler than) that of the proof of Lemma 4.4.

Since the category $\mathcal{A}$ admits finite direct sums, in order to check injectivity it suffices to show that for any class $\eta \in \text{Ext}^n_\mathcal{A}(X, Y)$ and morphism $g: \Lambda(Y) \to W$ in $\mathcal{B}$ such that $g\Lambda(\xi) = 0$ and $n \geq 1$ there exists a morphism $h: Y \to Z$ in $\mathcal{A}$ and a morphism $\tau: \Lambda(Z) \to W$ in $\mathcal{B}$ such that $g = \tau\Lambda(h)$ and $h\xi = 0$. Let us first consider the case $n = 1$. Present the class $\xi$ by an extension $Y \to Z \to X$; then the equation $g\Lambda(\xi) = 0$ means that the morphism $g$ factorizes through the morphism $\Lambda(Y) \to \Lambda(Z)$. So it suffices to take the admissible monomorphism $Y \to Z$ as $h$.

Now we return to the general case $n \geq 1$. Present the class $\xi$ as the composition of a class $\xi' \in \text{Ext}^{n-1}_\mathcal{A}(X, U)$ and a class $\theta \in \text{Ext}^1_\mathcal{A}(U, V)$. Set $\eta = g\Lambda(\theta)$; then we have $\eta\Lambda(\xi) = 0$. By Lemma 4.4, there exists a morphism $U' \to U$ in $\mathcal{A}$ and a class $\xi'' \in \text{Ext}^{n-1}_\mathcal{A}(X, U')$ such that $\xi = f\xi''$ and $\eta\Lambda(f) = 0$. Set $\theta' = \theta f$; then we have $g\Lambda(\theta') = 0$. Consequently, there exists a morphism $h: Y \to Z$ in $\mathcal{A}$ and a morphism $\tau: \Lambda(Z) \to W$ in $\mathcal{B}$ such that $g = \tau\Lambda(h)$ and $h\theta' = 0$. Then $h\xi = h\theta\xi' = h\theta f\xi'' = h\theta\xi' = 0$. □

4.5. Construction of the boundary map. It remains to obtain the long exact sequence (4.5); we start with constructing the boundary map $\partial: \text{Ext}^2_\mathcal{B}(\text{gr } X, \text{gr } Y) \to \text{Ext}^{2+1}_\mathcal{B}(X, Y(-1))$ for all $X, Y \in \mathcal{F}$ and $n \geq 0$.

Clearly, any object $(U, V)$ in $\mathcal{G}$ is the target of an admissible epimorphism $\text{gr } U = (U, U(-1)) \to (U, V)$; analogously, $(U, V)$ is the source of an admissible monomorphism into the object $\text{gr } V(1) = (V(1), V)$. Moreover, any admissible epimorphism $T \to \text{gr } X$ in $\mathcal{G}$ can be represented by a morphism $(U, V) \to (X, X(-1))$ in $\mathcal{H}$, hence there are admissible epimorphisms $U \to X$ in $\mathcal{F}$ and $\text{gr } U \to (U, V)$ in $\mathcal{G}$ such that the triangle $\text{gr } U \to (U, V) \to \text{gr } X$ commutes. So the exact functor $\text{gr}: \mathcal{F} \to \mathcal{G}$ satisfies the assumption of Lemmas 4.4–4.5.

To construct the image of a morphism $\text{gr } X \to \text{gr } Y$ under the homomorphism $\partial_0: \text{Hom}_\mathcal{H}(\text{gr } X, \text{gr } Y) \to \text{Ext}^2_\mathcal{F}(X, Y(-1))$, choose an admissible epimorphism $X' \to X$ and a morphism $X' \to Y$ in $\mathcal{F}$ such that the triangle $\text{gr } X' \to \text{gr } X \to \text{gr } Y$ commutes in $\mathcal{G}$. Let $K$ be the kernel of the admissible epimorphism $X' \to X$; then the composition $K \to X' \to Y$ is annihilated by the functor $\text{gr}$, and consequently factorizes through the morphism $\text{gr}_{Y(-1)}: Y(-1) \to Y$. The morphism $K \to Y(-1)$ that we have obtained induces from the exact triple $K \to X' \to Y$ the desired extension of $Y$ and $K(-1)$ in $\mathcal{F}$.

Alternatively, choose an admissible monomorphism $Y \to Y'$ and a morphism $X \to Y'$ in $\mathcal{F}$ such that the triangle $\text{gr } X \to \text{gr } Y \to \text{gr } Y'$ commutes in $\mathcal{G}$. Let $C$ be the cokernel of the admissible monomorphism $Y \to Y'$; then the composition $X \to Y' \to C$ is annihilated by the functor $\text{gr}$, so we obtain a morphism $X(1) \to C$. This morphism induces from the extension $Y \to Y' \to C$ an extension of $X(1)$ and $Y$ in $\mathcal{F}$. Let us show that the two extensions that we have obtained only differ by (a twist and) the minus sign.

The difference of the compositions $X' \to X \to Y'$ and $X' \to Y \to Y'$ is annihilated by the functor $\text{gr}$, so there is a morphism $X' \to Y'(1)$ in $\mathcal{F}$. Together
with the exact triples $K \to X' \to X$ and $Y \to Y' \to C$ and the morphisms $K \to Y(-1)$ and $X \to C(-1)$, this morphism forms a diagram in which one square commutes and the other one anticommutes. It follows immediately that the map $\text{Hom}_F^{\text{gr}}(X, Y) \to \text{Ext}_F^X(Y, (-1))$ given by either of the above two rules is a well-defined homomorphism of bimodules over the big ring $\text{Hom}_F(X, Y)$ over the set $\text{Ob} F$ of all objects of $F$.

By Lemma 4.5 and its dual version, the bimodule $(\text{Ext}_F^X(Y, (-1)))_{Y, X \in F, n \geq 0}$ over the big graded ring $(\text{Ext}_F^X(Y, (-1)))_{Y, X \in F}$ considered as either a left or right module is induced from its zero grading component

$$(\text{Hom}_F^{\text{gr}}(X, Y))_{Y, X \in F}$$

as a module over the zero grading component $(\text{Hom}_F(X, Y))_{Y, X \in F}$ of the big graded ring. We want our maps

$$\partial = \partial_n : \text{Ext}_F^X(Y, (-1)) \to \text{Ext}_F^{X+1}(Y, (-1))$$

to satisfy the equations $\partial(\Lambda(\xi)\eta) = (-1)^{[\xi]}\partial(\eta)\xi$ and $\partial(\eta\Lambda(\xi)) = \partial(\eta)\xi$ for any $\text{Ext}$ classes $\xi$ and $\eta$ of the degrees $[\xi]$ and $[\eta]$ in the exact category $F$ and any $\eta \in \text{Ext}_F^X(Y, (-1))$. Either of these two equations defines the sequence of maps $\partial_n$ uniquely, and one only has to check that the two conditions are compatible. It suffices to check this for a class in $\text{Ext}_F^X(Y, (-1))$ decomposed into the product of a class in $\text{Ext}_F(U, Y)$ and an element in $\text{Hom}_F^{\text{gr}}(X, U)$, and also into the product of a class in $\text{Ext}_F(X, Y)$ and an element in $\text{Hom}_F^{\text{gr}}(V, Y)$.

We have two exact triples $Y \to S \to U$ and $V \to T \to X$ in $F$ and a morphism of exact triples $(\text{gr} V \to \text{gr} T \to \text{gr} X) \to (\text{gr} Y \to \text{gr} S \to \text{gr} U)$ in $G$. Choose an admissible epimorphism $X' \to X$ in $F$ such that the composition $\text{gr} X' \to \text{gr} X \to \text{gr} U$ comes from a morphism $X' \to U$ in $F$. Denote by $T''$ the fibered product of $T$ and $X'$ over $X$. Choose an admissible epimorphism $T'' \to T'''$ such that the composition $\text{gr} T''' \to \text{gr} T \to \text{gr} S$ comes from a morphism $T'' \to S$ in $F$. Consider the difference of the compositions $T'' \to T''' \to X' \to U$ and $T'' \to S \to U$. It is annihilated by the functor $\text{gr}$, and consequently factorizes through the morphism $\sigma_{U(-1)}$; hence we get a morphism $T'' \to U(-1)$. Denote by $T'$ the fibered product of $T''$ and $S(-1)$ over $U(-1)$. Define the morphism $T' \to X'$ as the composition $T' \to T'' \to T''' \to X'$ and the morphism $T'' \to S$ as the sum of the compositions $T' \to T'' \to S$ and $T' \to S(-1) \to S$. Then the square formed by the morphisms $T' \to X' \to U$ and $T' \to S \to U$ is commutative, as is the triangle $\text{gr} T' \to \text{gr} T \to \text{gr} S$.

Let $V'$ be the kernel of the admissible epimorphism $T' \to X'$. Then there is an admissible epimorphism of exact triples $(V' \to T' \to X') \to (V \to T \to X)$ and a morphism of exact triples $(V' \to T' \to X') \to (Y \to X \to U)$ whose images in $G$ form a commutative triangle with the morphism of exact triples $(\text{gr} V \to \text{gr} T \to \text{gr} X) \to (\text{gr} Y \to \text{gr} S \to \text{gr} U)$. Let $K \to L \to M$ be the kernel of the admissible epimorphism $(V' \to T' \to X') \to (V \to T \to X)$. Then the morphism of exact triples $(K \to L \to M) \to (Y \to S \to U)$ is annihilated by the functor $\text{gr}$, so there is a morphism of exact triples $(K \to L \to M) \to (Y(-1) \to S(-1) \to U(-1))$. Consider the extension of exact triples $V \to T \to X$ and $Y(-1) \to S(-1) \to U(-1)$.
using the above morphism. We have obtained a commutative 3 \times 3 square formed
by exact triples. For any such square, the two Ext^2 classes between the objects at
the opposite vertices obtained by composing the Ext^1 classes along the perimeter
differ by the minus sign. This proves the desired equation in Ext^2_F(X, Y).

4.6. Exactness of the long sequence. Checking that the long sequence is a
complex is easy. We will start with proving exactness of the segment

\[ 0 \rightarrow \text{Hom}_F(X, Y(-1)) \rightarrow \text{Hom}_F(X, Y) \rightarrow \text{Hom}_G(\text{gr} X, \text{gr} Y) \]
\[ \rightarrow \text{Ext}^1_F(X, Y(-1)) \rightarrow \text{Ext}^1_F(X, Y) \rightarrow \text{Ext}^1_G(\text{gr} X, \text{gr} Y). \]

We have already explained in Section 4.1 that exactness at Hom_F(X, Y(-1)) fol-
walks from the conditions (4.1–4.2). Exactness at the term Hom_F(X, Y) is provided
by the condition (4.3). Let us prove exactness at the term Hom_G(\text{gr} X, \text{gr} Y). Sup-
pose we are given a morphism \text{gr} X \rightarrow \text{gr} Y, an admissible epimorphism \text{X}' \rightarrow \text{X},
and a morphism \text{X}' \rightarrow \text{Y} such that the triangle \text{gr} \text{X}' \rightarrow \text{gr} \text{X} \rightarrow \text{gr} \text{Y} commutes.
Let K be the kernel of the morphism \text{X} \rightarrow \text{Y} and the composition \text{K} \rightarrow \text{X}' \rightarrow \text{Y}
be factorized as \text{K} \rightarrow \text{Y}(-1) \rightarrow \text{Y}. Assume that the extension induced from
the extension \text{K} \rightarrow \text{X}' \rightarrow \text{Y} using the morphism \text{K} \rightarrow \text{Y}(-1) splits. Then the
morphism \text{K} \rightarrow \text{Y}(-1) factorizes through the morphism \text{K} \rightarrow \text{X}', so there is a
morphism \text{X}' \rightarrow \text{Y}(-1). Subtracting from the morphism \text{X}' \rightarrow \text{Y} the composition
\text{X}' \rightarrow \text{Y}(-1) \rightarrow \text{Y} we obtain a new morphism \text{X}' \rightarrow \text{Y} that annihilates \text{K}. Hence
this morphism factorizes through the admissible epimorphism \text{X}' \rightarrow \text{X}, providing
the desired morphism \text{X} \rightarrow \text{Y}.

Let us check exactness at the term Ext^1_F(X, Y(-1)). Suppose we are given an
extension \text{Y}(-1) \rightarrow \text{Z} \rightarrow \text{X} such that the morphism \sigma_{\text{Y}(-1)} factorizes through
the admissible monomorphism \text{Y}(-1) \rightarrow \text{Z}. Then we have a morphism \text{Z} \rightarrow \text{Y},
and the induced morphism \text{gr} \text{Z} \rightarrow \text{gr} \text{Y} annihilates the admissible monomorphism
\text{gr} \text{Y}(-1) \rightarrow \text{gr} \text{Z}. Consequently, the morphism \text{gr} \text{Z} \rightarrow \text{gr} \text{Y} factorizes through the
admissible epimorphism \text{gr} \text{Z} \rightarrow \text{gr} \text{X}, providing a morphism \text{f}: \text{gr} \text{X} \rightarrow \text{gr} \text{Y}. By
the definition, the class of our extension \text{Y}(-1) \rightarrow \text{Z} \rightarrow \text{X} is equal to \partial \text{f}.

Let us prove exactness at the term Ext^1_F(X, Y). Suppose that an exact triple
\text{Y} \rightarrow \text{Z} \rightarrow \text{X} becomes split after the functor \text{gr} is applied to it. Then there
exists a splitting morphism \text{gr} \text{X} \rightarrow \text{gr} \text{Z}. Consequently, there exist an admissible epimorphism \text{f}: \text{X}' \rightarrow \text{X}
and a morphism \text{X}' \rightarrow \text{Z} such that the composition
\text{X}' \rightarrow \text{Z} \rightarrow \text{X} is the sum of \text{f} and a morphism annihilated by \text{gr}, while the
composition \text{Ker}(\text{f}) \rightarrow \text{X}' \rightarrow \text{Z} is also annihilated by \text{gr}. Let \text{g}: \text{X}' \rightarrow \text{X} be the
sum of the morphism \text{f} and the composition \text{X}' \rightarrow \text{Z} \rightarrow \text{X}. Then \text{g} is also an
admissible epimorphism, since \text{gr} \text{g} is; and the composition \text{Ker}(\text{g}) \rightarrow \text{X}' \rightarrow \text{Z} is
also annihilated by \text{gr}, since \text{gr} \text{g} = \text{gr} \text{f}. Now our exact triple \text{Y} \rightarrow \text{Z} \rightarrow \text{X} is
induced from the exact triple \text{Ker}(\text{g}) \rightarrow \text{X}' \rightarrow \text{X} by a morphism \text{Ker}(\text{g}) \rightarrow \text{Y}
annihilated by \text{gr}. Since the latter map factorizes through \sigma_{\text{Y}(-1)}, we are done.

Exactness at the further terms can be deduced from the exactness in this initial
segment using Lemma 4.4 applied to the functors \text{Id}_F and \text{gr}: \mathcal{F} \rightarrow \mathcal{G}. \hfill \Box
5. Restriction of Base

Let $\mathcal{G}$ be an exact category endowed with a sequence of full subcategories $\mathcal{E}_i$, $i \in \mathbb{Z}$. Assume that each subcategory $\mathcal{E}_i$ is closed under extensions and every object of $\mathcal{G}$ is an iterated extension of objects from $\mathcal{E}_i$. Furthermore, assume that the induced exact category structures on $\mathcal{E}_i$ are trivial, i.e., for any $i \in \mathbb{Z}$ every exact triple in $\mathcal{E}_i \subset \mathcal{G}$ splits. 

Finally, assume that the groups $\text{Hom}$ and $\text{Ext}^1$ in the category $\mathcal{G}$ satisfy the conditions (4.4).

Let $\mathcal{A}_i$ be additive categories and $\psi_i: \mathcal{A}_i \to \mathcal{E}_i$ be additive functors such that every object of $\mathcal{E}_i$ is a direct summand of an object coming from $\mathcal{A}_i$. 

Let $\mathcal{H}$ denote the category whose objects are the triples $(X, Q, \rho)$, where $Q \in \prod_i \mathcal{A}_i$ is a finitely supported graded object, $X$ is an object of $\mathcal{G}$, and $\rho: q(X) \to \psi(Q)$ is an isomorphism in $\prod_i \mathcal{E}_i$ (cf. Section 3), where $q$ denotes the functor of “successive quotients” $\mathcal{G} \to \prod_i \mathcal{E}_i$ (see Section 4.1) and $\psi = (\psi_i)$.

The category $\mathcal{H}$ has an exact category structure in which a short sequence is exact if the related sequence of graded objects $Q$ is split exact. The additive categories $\mathcal{A}_i$ can be considered as the full subcategories of $\mathcal{H}$ consisting of all the triples $(X, Q, \rho)$ such that $Q_j = 0$ for $j \neq i$. Then the exact category $\mathcal{H}$ with the full subcategories $\mathcal{A}_i$ satisfies all the above conditions (5.1) and (4.4) imposed on the exact category $\mathcal{G}$ with the full subcategories $\mathcal{E}_i$.

There is the natural (forgetful) exact functor $\Psi: \mathcal{H} \to \mathcal{G}$.

Example 5.1. Let $S \to R$ be a morphism of rings, $\mathcal{E}$ be the category of finitely generated projective left $R$-modules, $\mathcal{A}$ be the category of finitely generated projective left $S$-modules, and $\psi: \mathcal{A} \to \mathcal{E}$ be the functor of extension of scalars, $\psi(N) = R \otimes_S N$. Then the functor $\psi$ satisfies (5.2).

Theorem 5.2. The homomorphism $\text{Ext}^n_\mathcal{H}(X, Y) \to \text{Ext}^n_\mathcal{G}(\Psi(X), \Psi(Y))$ induced by the functor $\Psi$ are

1. epimorphisms for all $n \geq 1$ and $X, Y \in \mathcal{H}$;
2. isomorphisms for $n = 1$ and $X, Y \in \mathcal{H}$, if the graded objects $q(X)$ and $q(Y) \in \prod_i \mathcal{A}_i$ are supported in disjoint sets of indices $i$;
3. isomorphisms for all $n \geq 2$ and $X, Y \in \mathcal{H}$.

Proof. Let $\mathcal{A}_i'$ be the additive category obtained by adjoining to $\mathcal{A}_i$ the images of those idempotent endomorphisms $p$ for which the image of $\psi_i(p)$ exists in $\mathcal{E}_i$. Then the functor $\psi_i: \mathcal{A}_i \to \mathcal{E}_i$ factorizes through the embedding $\mathcal{A}_i \to \mathcal{A}_i'$, so there is an additive functor $\psi'_i: \mathcal{A}_i' \to \mathcal{E}_i$. According to (5.2), the functors $\psi'_i$ are surjective on the isomorphism classes of objects. The same construction as above provides the exact category $\mathcal{H}'$ with the full subcategories $\mathcal{A}_i'$, the embedding of exact categories $\mathcal{H} \to \mathcal{H}'$, and the exact functor $\Psi': \mathcal{H}' \to \mathcal{G}$. The full exact subcategory $\mathcal{H}$ is closed under extensions in $\mathcal{H}'$ and all objects of the exact category $\mathcal{H}'$ are direct summands of certain objects of $\mathcal{H}$, hence the embedding $\mathcal{H} \to \mathcal{H}'$ induces isomorphisms on $\text{Ext}^n(X, Y)$ for all $n \geq 0$ and $X, Y \in \mathcal{H}$ (see Corollary A.18). This reduces the problem to the case when the additive functors $\psi_i$ are surjective on the isomorphism
Consider the related split exact triple
\[ q \]
recover the original exact category \( G \) for \( n = 1 \). Suppose that we are given an exact triple \( \Psi(Y) \to T \to \Psi(X) \) in \( G \). Let \( i < r < j \). Choosing a splitting, one can identify \( q(T) \) with \( q(\Psi(Y) \oplus q(\Psi(X) \cong \psi(q(Y) \oplus q(X))). \) This defines a lifting of the object \( T \in G \) to an object \( Z \in H \) and of the exact triple \( \Psi(Y) \to T \to \Psi(X) \) to an exact triple \( Y \to Z \to X \) in \( H \). Part (2) is obvious, since in its assumptions any splitting of the exact triple \( \Psi(Y) \to \Psi(Z) \to \Psi(X) \) is simultaneously a splitting of the exact triple \( Y \to Z \to X \).

It follows from surjectivity on \( \text{Ext}^1 \) by means of the five-lemma and induction on the number of iterated extensions that it suffices to check injectivity on \( \text{Ext}^2 \) in the case when \( X \in A_i \) and \( Y \in A_j \) for some \( i, j \in \mathbb{Z} \). Present our class in \( \text{Ext}^2_{\mathcal{H}}(X, Y) \) as the composition of some classes in \( \text{Ext}^1_{\mathcal{H}}(X, Z) \) and \( \text{Ext}^1_{\mathcal{H}}(Z, Y) \). It was explained in Section 3.2 that one can choose \( Z \in H_{[r, j]} \); since we now assume the exact category structures on \( A_i \) to be trivial, one can actually choose \( Z \in H_{[i, j - 1]} \), for the same reason. Let these classes \( \text{Ext}^1 \) be presented by exact triples \( Y \to U \to Z \) and \( Z \to V \to X \). The class \( \text{Ext}^2_{\mathcal{H}}(\Psi(X), \Psi(Y)) \) represented by the Yoneda extension \( \Psi(Y) \to \Psi(U) \to \Psi(V) \to \Psi(X) \) is trivial if and only if one can decompose the morphism \( \Psi(U) \to \Psi(V) \) as \( \Psi(U) \to T \to \Psi(V) \) in such a way that the triples \( \Psi(Y) \to T \to \Psi(V) \) and \( \Psi(U) \to T \to \Psi(X) \) are exact (see Corollary A.14). In this case one has \( q_r(T) \simeq q_r(\Psi(X)), q_r(T) \simeq q_r(\Psi(Z)) \) for \( i < r < j \), and \( q_r(T) \simeq q_r(\Psi(Y)) \) (see Section 4 for the notation \( q_r(T) \); cf. Section 3.2). This allows to lift the object \( T \in G \) to an object \( W \in H \) in such a way that the diagram remains commutative and the triples remain exact. Then the original class in \( \text{Ext}^2_{\mathcal{H}}(X, Y) \) is also trivial.

Finally, let us prove injectivity on \( \text{Ext}^n \) for \( n \geq 3 \) using injectivity on \( \text{Ext}^{n-1} \). Notice that the functor \( \Psi : H \to G \) satisfies the assumption of Lemma 4.4. Indeed, for any admissible epimorphism \( T \to \Psi(X) \) in \( G \) one can lift the object \( T \) to an object \( W \in H \) in such a way that the morphism \( T \to \Psi(X) \) lifts to an admissible epimorphism \( W \to X \) in \( H \). Now consider a class in \( \text{Ext}^n_{\mathcal{H}}(X, Y) \) and decompose it into the product of classes in \( \text{Ext}^1_{\mathcal{H}}(X, Z) \) and \( \text{Ext}^{n-1}_{\mathcal{H}}(Z, Y) \). Assume that the product of the images of these classes in \( \text{Ext}^1_{\mathcal{H}}(\Psi(X), \Psi(Z)) \) and \( \text{Ext}^{n-1}_{\mathcal{H}}(\Psi(Z), \Psi(Y)) \) vanishes. By the mentioned lemma, there exists a morphism \( Z' \to Z \) in \( H \) such that the class in \( \text{Ext}^1_{\mathcal{H}}(X, Z) \) comes from a class in \( \text{Ext}^1_{\mathcal{H}}(X, Z') \) and the composition of the morphism \( \Psi(Z') \to \Psi(Z) \) in \( G \) with the class in \( \text{Ext}^{n-1}_{\mathcal{H}}(\Psi(Z), \Psi(Y)) \) vanishes. Since the map \( \text{Ext}^{n-1}_{\mathcal{H}}(Z', Y) \to \text{Ext}^{n-1}_{\mathcal{H}}(\Psi(Z'), \Psi(Y)) \) is injective, it follows that the composition of the morphism \( Z' \to Z \) in \( H \) with the class in \( \text{Ext}^{n-1}_{\mathcal{H}}(Z, Y) \) also vanishes. Therefore, the original class in \( \text{Ext}^n_{\mathcal{H}}(X, Y) \) is zero. \( \square \)
6. Diagonal Cohomology

6.1. Diagonal Ext is quadratic. Let $\mathcal{D}$ be a small triangulated category endowed with a sequence of full subcategories $\mathcal{E}_i$, $i \in \mathbb{Z}$. Assume that each $\mathcal{E}_i$ is closed under extensions in $\mathcal{D}$ and one has

$$\text{Hom}_\mathcal{D}(X, Y[1]) = 0 \text{ for all } X \in \mathcal{E}_i, Y \in \mathcal{E}_j, \text{ and } i \geq j. \quad (6.1)$$

Finally, suppose that a triangulated autoequivalence $X \mapsto X(1)$ is defined on the triangulated category $\mathcal{D}$ such that $\mathcal{E}_i(1) = \mathcal{E}_{i+1}$. Let $\mathcal{J}$ be a full subcategory of $\mathcal{E}_0$ such that any object of $\mathcal{E}_0$ is a finite direct sum of objects from $\mathcal{J}$. Introduce the big graded ring of diagonal cohomology $A = (\text{Hom}_\mathcal{D}(X, Y(n)[n]))_{Y, X \in \mathcal{J}, n \geq 0}$ over the set $\text{Ob} \mathcal{J}$ of all objects of $\mathcal{J}$ (see Section A.1). Let $\mathcal{M}$ denote the minimal full subcategory of $\mathcal{D}$ containing all $\mathcal{E}_i$ and closed under extensions.

Theorem 6.1. Assume that every morphism $X \to Y[n]$ of degree $n \geq 2$ in $\mathcal{D}$ between two objects $X, Y \in \mathcal{M}$ can be presented as the composition of a chain of morphisms $Z_{i-1} \to Z_i[1]$ with $Z_i \in \mathcal{M}$, $Z_0 = X$, and $Z_n = Y$ (cf. Appendix B). Then

1. one has $\text{Hom}_\mathcal{D}(X, Y[n]) = 0$ for all $X \in \mathcal{E}_i, Y \in \mathcal{E}_j$, $n \geq 1$, and $n > j - i$;
2. the big graded ring $A$ is quadratic, i.e., generated by the $A_0$-bimodule $A_1$ with relations in degree 2.

More precisely, a big graded ring $A = \bigoplus_{n=0}^{\infty} A_n$ is said to be quadratic if the natural maps

$$A_1^{\otimes n}/\sum_{1 \leq j \leq n-1} A_1^{\otimes j-1} \otimes A_0 I \otimes A_0 A_1^{\otimes n-j-1} \to A_n$$

are isomorphisms for all $n \geq 2$, where the tensor powers of the $A_0$-bimodule $A_1$ are taken over $A_0$ and the $A_0$-bimodule of quadratic relations $I$ is defined as the kernel of the multiplication map $A_1 \otimes_{A_0} A_1 \to A_2$.

Notice that the property of a big graded ring $A$ to be quadratic actually does not depend on the component $A_0$, i.e., for any big graded ring $A$ and a morphism of big rings $A'_0 \to A_0$ over the same set $\Sigma$ the big graded rings $A$ and $A' = A'_0 \oplus A_1 \oplus A_2 \oplus \cdots$ are quadratic simultaneously. Indeed, clearly $A$ is generated by $A_1$ over $A_0$ if and only if $A'$ is generated by $A_1$ over $A'_0$; and the relation $(ar)b = a(rb)$ for $a, b \in A_1$ and $r \in A_0$ has degree 2.

Proof. As in Section 3.2, denote by $\mathcal{M}_{[i,j]}$ the minimal full subcategory of $\mathcal{D}$, containing $\mathcal{E}_r$, $i \leq r \leq j$, and closed under extensions. It follows from the *-associativity lemma [4, Lemma 3.1.10] and the condition (6.1) that one has $\mathcal{M}_{[i,j]} = \mathcal{M}_{[r+1,j]} * \mathcal{M}_{[i,r]}$ for any $i \leq r < j$, i.e., for any object $Z \in \mathcal{M}_{[i,j]}$ there exists a distinguished triangle $Z_{\geq r+1} \to Z \to Z_{\leq r} \to Z_{\geq r+1}[1]$ with $Z_{\geq r+1} \in \mathcal{M}_{[r+1,j]}$ and $Z_{\leq r} \in \mathcal{M}_{[i,r]}$. This triangle does not have to be unique or functorial in our weak assumptions (6.1).

However, it follows from these assumptions that, given $X \in \mathcal{M}_{[i,+,\infty)}$ and $Y \in \mathcal{M}$, any element in $\text{Hom}_\mathcal{D}(X, Y[1])$ comes from an element in $\text{Hom}_\mathcal{D}(X, Y_{\geq i+1}[1])$ (for any choice of $Y_{\geq i+1}$). Decomposing an arbitrary element of $\text{Hom}_\mathcal{D}(X, Y[n])$ with $n \geq 1$ into the product of elements from $\text{Hom}_\mathcal{D}(\mathcal{M}, \mathcal{M}[1])$ and using in-
A should be identified with \( \Sigma \), and the big graded ring of diagonal cohomology is a direct sum of objects from \( J \) into a product of elements from \( \text{Hom}_D(n, Z[i]) \) with \( Z_i \in \mathcal{E}_i \). Taking \( X \in \mathcal{J} \), \( Y \in \mathcal{J}(n) \) and presenting \( Z_i \) as finite direct sums of objects from \( \mathcal{J}(i) \), one can show that the big graded ring \( A \) is generated by \( A_1 \).

It remains to prove quadraticity. With any relation of degree \( n \) between the elements of \( A_1 \) in the big graded ring \( A \) one can associate a relation of the form \( \xi_1 \cdots \xi_n = 0 \) in the big graded ring \( \text{Hom}_D(X, Y[n]) \) with \( \xi_i \in \text{Hom}(Z_{i-1}, Z_i[1]) \) and \( Z_i \in \mathcal{E}_i \). Let us show that all such relations follow from relations of degree 2. Assume that the product of an element \( \xi \in \text{Hom}_D(X, Y[1]) \) and a class \( \eta \in \text{Hom}_D(Z[1], Y[n]) \) is zero, where \( X \in \mathcal{E}_0 \), \( Z \in \mathcal{E}_1 \), \( Y \in \mathcal{E}_n \), and \( n \geq 3 \).

Consider the distinguished triangle \( Z \rightarrow T \rightarrow X \rightarrow Z[1] \); then the object \( T \) belongs to \( \mathcal{M}_{[0,1]} \). Since \( \eta \xi = 0 \), the morphism \( \eta \) extends to a morphism \( \eta' \in \text{Hom}_D(T[1], Y[n]) \). By the assumption of the theorem, one can decompose the morphism \( \eta' \) as a product of a morphism \( T[1] \rightarrow S[2] \) and a morphism \( S[2] \rightarrow Y[n] \) in \( D \), where \( S \in \mathcal{M} \). As explained above, one can assume that \( S \in \mathcal{M}_{[1,2]} \). So there is a distinguished triangle \( U \rightarrow S \rightarrow V \rightarrow U[1] \) with \( U \in \mathcal{E}_2 \) and \( V \in \mathcal{E}_1 \). Denote the morphism \( V[1] \rightarrow U[2] \) by \( \theta \). The composition \( \xi \in \text{Hom}_D(Z[1], Y[1]) \) factorizes through the morphism \( U[2] \rightarrow S[2] \), providing a morphism \( \zeta : Z[1] \rightarrow U[2] \). The composition \( X \rightarrow Z[1] \rightarrow U[2] \rightarrow S[2] \) vanishes, since the composition \( X \rightarrow S[2] \rightarrow U[2] \) does; hence the composition \( X \rightarrow Z[1] \rightarrow U[2] \) factorizes through the morphism \( \theta \), providing a morphism \( \chi : X \rightarrow V[1] \). Denote the composition \( U[2] \rightarrow S[2] \rightarrow Y[n] \) by \( \lambda \). Now the relation \( \eta \xi = 0 \) of degree \( n \) follows from the relations \( \eta \chi = 0 \), \( \zeta \xi = \theta \chi \), and \( \lambda \theta = 0 \) of the degrees \( n-1 \), \( 2 \), and \( n-1 \), respectively.

Decomposing the objects \( V \) and \( U \) into finite direct sums of objects from \( \mathcal{J}(1) \) and \( \mathcal{J}(2) \), one can conclude that the original relation of degree \( n \) in \( A \) follows from relations of degree \( \leq n-1 \).

**6.2. Any quadratic ring can be realized.** Let \( A \) be a big nonnegatively graded ring over a set \( \Sigma \); suppose that \( A \) is quadratic. Starting from \( A \), we would like to construct an exact category \( \mathcal{G} \) with the following properties.

The exact category \( \mathcal{G} \) should be endowed with a sequence of full subcategories \( \mathcal{E}_i \) and an exact autoequivalence \( X \mapsto X(1) \) such that each \( \mathcal{E}_i \) is closed under extensions, every object of \( \mathcal{G} \) is an iterated extension of objects from \( \mathcal{E}_1 \), and \( \mathcal{E}_1(1) = \mathcal{E}_{i+1} \). The conditions (4.4) and (5.1) should be satisfied.

There should be a full subcategory \( \mathcal{J} \subset \mathcal{E}_0 \) such that every object of \( \mathcal{E}_0 \) is a finite direct sum of objects from \( \mathcal{J} \). The set \( \text{Ob} \mathcal{J} \) of all objects of \( \mathcal{J} \) should be identified with \( \Sigma \), and the big graded ring of diagonal cohomology

\[
\left( \text{Ext}_{\mathcal{G}}^n(X, Y[n]) \right)_{Y \in \mathcal{J}; n \geq 0}
\]

should be identified with \( A \).

Finally, one should have

\[
\text{Ext}_{\mathcal{G}}^n(X, Y) = 0 \quad \text{for all } X \in \mathcal{E}_i, Y \in \mathcal{E}_j, n \leq j - i, \text{ and } n = 1 \text{ or } 2.
\] (6.2)
Notice that the conditions (4.4) and (5.1) imply \( \text{Ext}_G^n(X, Y) = 0 \) for \( n > j - i \) by the result from Section 6.1. So the sum total of the conditions (4.4), (5.1), and (6.2) can be simply restated as

\[
\text{Ext}_G^n(X, Y) = 0 \quad \text{for all } X \in \mathcal{E}_i, \ Y \in \mathcal{E}_j, \ n \neq j - i, \text{ and } n \leq 2. \quad (6.3)
\]

**Theorem 6.2.** For any quadratic big graded ring \( A \) over a set \( \Sigma \) there exists a unique, up to a unique exact equivalence, exact category \( \mathcal{G} \) with the additional data described above satisfying the condition (6.3).

We will give two proofs of this theorem, both of which will be useful in the sequel.

**First proof.** Consider the big ring \( R = A_0 \). We will construct the category \( \mathcal{G} \) as a certain category of graded comodules over a graded coring over the big ring \( R \).

Generally, a coring \( C \) over \( R \) is an \( R \)-bimodule endowed with \( R \)-bimodule maps \( C \to C \otimes_R C \) and \( C \to R \), called the comultiplication and counit, satisfying the conventional coassociativity and counit axioms. A right \( C \)-comodule \( N \) over a coring \( C \) is a right \( R \)-module endowed with an \( R \)-module map \( N \to N \otimes_R C \), called the right coaction, satisfying the conventional axioms.

Let \( C = C_0 \oplus C_{-1} \oplus C_{-2} \oplus \cdots \) be a nonpositively graded coring over a big ring \( R \) such that \( C_0 = R \). Such a coring \( C \) is said to be quadratic if the comultiplication map \( C_{-2} \to C_{-1} \otimes_R C_{-1} \) is injective and \( C \) is the universal final object in the category of graded corings over \( R \) with the components \( C_0, \ C_{-1}, \) and \( C_{-2} \) fixed.

Given an \( R \)-bimodule \( C_{-1} \) and a subbimodule \( C_{-2} \subseteq C_{-1} \otimes C_{-1} \), the corresponding quadratic coring \( C \) always exists. Its components can be constructed by induction in such a way that the initial fragment of the reduced cobar-complex

\[
0 \to C_+ \to C_+ \otimes_R C_+ \to C_+ \otimes_R C_+ \otimes_R C_+,
\]

where \( C_+ = C/R \), would be exact in the gradings \(-3\) and below.

The coring \( C \) we are interested in is the quadratic coring over \( R \) with the initial components \( C_{-1} = A_1 \) and \( C_{-2} = I = \text{Ker}(A_1 \otimes_R A_1 \to A_2) \). The quadratic coring \( C \) constructed in this way is called quadratic dual to the quadratic big ring \( A \).

For any finite set mapping to \( \Sigma \) one can consider the corresponding finitely generated free right \( R \)-module (see Section A.1). The additive category \( \mathcal{E}_0 \) of such \( R \)-modules is endowed with the full subcategory \( \mathcal{J} \) consisting of free modules with one generator; the set \( \text{Ob} \mathcal{J} \) is identified with \( \Sigma \) and the big ring \( (\text{Hom}_G(X, Y))_{Y \in \mathcal{J}} \) is naturally identified with \( R \). Set \( \mathcal{G} \) to be the category of graded right \( C \)-comodules that are free and finitely generated as graded right \( R \)-modules. The full subcategories \( \mathcal{E}_i \) consist of the graded comodules concentrated in degree \( i \); the twist functor \( X \mapsto X(1) \) shifts the grading. A triple in \( \mathcal{G} \) is exact if it is (split) exact in every degree.

The conditions (4.4) and (5.1) are obviously satisfied. It is also clear that \( \text{Ext}_G^n(X, Y) = 0 \) for all \( X \in \mathcal{E}_i, \ Y \in \mathcal{E}_j, \) and \( j - i > 1 \), since \( C \) is cogenerated by \( C_{-1} \). To show that \( \text{Ext}_G^1(X, Y) = 0 \) for all \( X \in \mathcal{E}_i, \ Y \in \mathcal{E}_j, \) and \( j - i > 2 \), present an arbitrary class in \( \text{Ext}_G^1(X, Y) \) as the product of classes in \( \text{Ext}_G^1(X, Z) \) and \( \text{Ext}_G^1(Z, Y) \), where \( Z \in \mathcal{G}_{\{i+1, j-1\}} \). Since \( C \) is quadratic, one can check that the \( C \)-comodule structures on the graded \( R \)-modules \( X \oplus Z \) and \( Z \oplus Y \) can be extended to a \( C \)-comodule structure on \( X \oplus Z \oplus Y \).
It is straightforward to identify the $R$-bimodule $(\Ext^1_D(X, Y(1)))_{Y, X \in \mathcal{J}}$ with $A_1$ and the $R$-bimodule $(\Ext^2_D(X, Y(2)))_{Y, X \in \mathcal{J}}$ with $A_2$. Thus the big graded ring $(\Ext^2_D(X, Y(n)))_{Y, X \in \mathcal{J}, n \geq 0}$ is isomorphic to $A$ by the result of Section 6.1.

Conversely, let $\mathcal{H}$ be an exact category with the additional data satisfying all the conditions of the theorem except perhaps (6.2). Then it is not difficult to construct an exact functor $\Lambda: \mathcal{H} \to \mathcal{G}$, where $\mathcal{G}$ is the above category of $C$-comodules. More precisely, one starts with identifying the additive subcategories $\mathcal{E}_i \subset \mathcal{H}$ with the category of finitely generated free right $R$-modules. Then one constructs the exact functors $\mathcal{H}_{[i, i+1]} \to \mathcal{G}$ using the class $\Ext^1_D(X, Y)$ for $X \in \mathcal{E}_i$ and $Y \in \mathcal{E}_{i+1}$ to define the coaction map $\Lambda(X) \to \Lambda(Y) \otimes_R C_{-1}$. To construct the graded $C$-comodule structure corresponding to an arbitrary object in $\mathcal{H}$, one only has to check that the compositions $\Lambda(X) \to \Lambda(Z) \otimes_R C_{-1} \to \Lambda(Y) \otimes_R C_{-1} \otimes_R C_{-1}$ factorize through $\Lambda(Y) \otimes_R C_{-2}$ whenever $X = q_i(W)$, $Z = q_{i+1}(W)$, and $Y = q_{i+2}(W)$ for some $W \in \mathcal{H}$. This is so because the product of the classes in $\Ext^1_D(X, Z)$ and $\Ext^1_D(Z, Y)$ corresponding to $W$ vanishes in $\Ext^2_D(X, Y)$.

If the category $\mathcal{H}$ also satisfies (6.2), then the functor $\Lambda$ is an equivalence of exact categories by Lemma 3.2.

Second proof. This is only a proof of existence. Consider the DG-category $\mathcal{C}$ whose objects are indexed by the pairs $(\sigma, i)$, where $\sigma \in \Sigma$ and $n \in \mathbb{Z}$. The complex of morphisms $\Hom\mathcal{C}(\tau, i)$, $(\sigma, j)$ has its only possibly nonzero term equal to $A_{\sigma, j-i}$ in the cohomological degree $j-i$. The composition of morphisms in $\mathcal{C}$ comes from the multiplication in $A$.

Let $\mathcal{D}$ denote the derived category of contravariant DG-functors from $\mathcal{C}$ to the category of complexes of abelian groups. There is an autoequivalence $(\sigma, i) \mapsto (\sigma, i-1)$ on the DG-category $\mathcal{C}$; let $X \mapsto X(1)$ denotes the induced autoequivalence of $\mathcal{D}$. Let $\mathcal{J} \subset \mathcal{D}$ be the full subcategory of functors representable by the objects $(\sigma, 0)$. Set $\mathcal{E}_0 \subset \mathcal{D}$ to be the minimal additive subcategory of $\mathcal{D}$ containing $\mathcal{J}$ and $\mathcal{E}_i = \mathcal{E}_0(i)$. Let $\mathcal{E}$ be the minimal full subcategory of $\mathcal{D}$ containing $\mathcal{E}_i$ and closed under extensions; then $\mathcal{E}$ has a natural structure of exact category.

Clearly, one has $\Hom_D(X, Y[n]) = 0$ for $X \in \mathcal{E}_i$, $Y \in \mathcal{E}_j$, and $n \neq j-i$. The big graded ring $(\Hom_D(X, Y(n)[n]))_{Y, X \in \mathcal{J}, n \geq 0}$ is identified with $A$. Since the natural maps $\Ext^1_D(X, Y) \to \Hom_D(X, Y[n])$ are isomorphisms for all $X, Y \in \mathcal{E}$ and $n \leq 1$, and monomorphisms for $n = 2$, the condition (6.3) follows. Since the big graded ring $\Ext^2_D(X, Y(n))_{Y, X \in \mathcal{J}, n \geq 0}$ is quadratic by the result from Section 6.1, its morphism to $A$ has to be an isomorphism.

7. Koszul Big Rings

Let $A = A_0 \oplus A_1 \oplus A_2 \oplus \cdots$ be a big graded ring over a set $\Sigma$. A big graded ring $A$ is called Koszul if there exists an exact category $\mathcal{G}$ with full subcategories $\mathcal{E}_i$, a twist functor $X \mapsto X(1)$ on it, and a full subcategory $\mathcal{J} \subset \mathcal{E}_0$ satisfying the assumptions of Section 6.2, for which the following stronger version of the condition (6.3) holds

$$\Ext^2_D(X, Y) = 0 \quad \text{for all } X \in \mathcal{E}_i, Y \in \mathcal{E}_j, \text{ and } n \neq j-i. \quad (7.1)$$

In other words, $A$ is Koszul if the exact category $\mathcal{G}$ uniquely determined by the conditions of Section 6.2 (including (6.2)), satisfies (7.1). By Theorem 6.1, this
condition always holds for \( n > j - i \); the nontrivial part is the vanishing for \( 3 \leq n < j - i \).

It follows from the result of Section 5 that the Koszul property does not depend on the base ring in the component of degree 0 of \( A \). More precisely, set \( R = A_0 \) and let \( S \to R \) be any morphism of big rings over \( \Sigma \). In addition to \( A \), consider the big graded ring \( B = S \oplus A_1 \oplus A_2 \oplus \cdots \). Then the big graded ring \( A \) is Koszul if and only if the big graded ring \( B \) is (cf. remarks before the proof in Section 6.1).

It is known [38, Sections 0.4 and 11.4] what the Koszulity condition means in the case of a nonnegatively graded ring \( A \) that is a flat left or right module over its zero-degree component \( R = A_0 \). We will see below in Section 7.3 that our definition is equivalent to the definition from [38] in the flat situation. For the reader’s convenience, we present a brief general discussion of flat Koszulity over a base big ring in Section 7.4.

One would like also to have a more explicit definition of Koszulity in the general case. Morally, the idea is to replace \( R \) with the “absolute ring”, known also as the “field with one element” \( \mathbb{F}_1 \); one presumes that every module over \( \mathbb{F}_1 \) is flat. In practice, this turns out to involve a certain condition of “exactness of the matrix Koszul complex” for \( A \). This is worked out, in two different ways, in Sections 7.1 and 7.2.

**Remark 7.1.** One might think that the simplest way to interpret the condition (7.1) would be to compute explicitly the groups \( \text{Ext} \) over the graded coring \( C \) constructed in the first proof in Section 6.2. The problem is, it is not known how to compute \( \text{Ext} \) in the exact category of \( R \)-projective comodules over a coring \( C \) over a ring \( R \) in general; see [38, Question 5.1.4]. In the flat case, we use this approach in Section 7.3.

**Example 7.2.** Any big graded ring \( A \) such that \( A_n = 0 \) for \( n \geq 2 \) is Koszul. The objects of the related exact category \( \mathcal{G} \) (as constructed in the first proof in Section 6.2) are finitely supported sequences of finitely generated free right \( A_0 \)-modules \( N_i \), \( i \in \mathbb{Z} \), endowed with right \( A_0 \)-module maps \( N_i \to N_{i+1} \otimes_{A_0} A_1 \). No compatibility condition is imposed on these maps. The subcategory \( \mathcal{E}_i \) consists of all sequences \( N \) such that \( N_j = 0 \) for \( j \neq i \), and \( \mathcal{J} \subset \mathcal{E}_0 \) is the subcategory of free modules with one generator. One easily checks that \( \text{Ext}^2_\mathcal{G}(X, Y) = 0 \) for any \( X \in \mathcal{E}_i \) and \( Y \in \mathcal{E}_j \subset \mathcal{G} \), so \( \mathcal{G} \) is an exact category of homological dimension 1 and (7.1) is satisfied.

**7.1. General case.** A \( \Sigma \)-colored matrix \( M \) with entries in \( A_m \) is a (finite, rectangular) matrix whose rows and columns are marked by elements of \( \Sigma \) and the entry \( M_{ij} \) belongs to the group \( A_{\sigma \tau, m} \) if the \( i \)-th row is marked by \( \sigma \) and the \( j \)-th column is marked by \( \tau \in \Sigma \). A pair of \( \Sigma \)-colored matrices \( (M, N) \) with entries in \( A_m \) and \( A_n \), respectively, is called composable if the number of columns in \( M \) equals the number of rows in \( N \) and the columns in \( M \) and rows in \( N \) corresponding to each other are marked by the same elements of \( \Sigma \). Clearly, the product \( MN \) of any two composable matrices \( M \) and \( N \) is well-defined as a \( \Sigma \)-colored matrix with entries in \( A_{m+n} \).
Theorem 7.3. A big nonnegatively graded ring $A$ is Koszul if and only if the following condition holds. Let $M(1), \ldots, M(m)$, $m \geq 0$ be $\Sigma$-colored matrices with entries in $A_1$ such that every pair $(M(i+1), M(i))$ is composable and the product $M(i+1)M(i)$ is zero. Let $N$ be a $\Sigma$-colored matrix with entries in $A_n$, $n \geq 1$, such that the pair $(N, M(m))$ is composable and the product $NM(m)$ is also zero. Then there should exist $\Sigma$-colored matrices $K(1), \ldots, K(m)$ with entries in $A_0$, $M(1)\ldots, M(m)$ with entries in $A_1$, $P$ with entries in $A_1$, and $Q$ with entries in $A_{n-1}$ such that

\[
M(1) = K(1)M', \quad M(2)K(1) = K(2)M', \quad \ldots, \quad M(m)K(m-1) = K(m)M', \quad NK(m) = QP, \quad M(i+1)M(i) = 0 \text{ for all } i = 1, \ldots, m-1, \quad \text{and } PM' = 0,
\]

where all the pairs of matrices being multiplied are composable.

Proof. Notice first of all that the condition for $n = 1$ is always trivial: it suffices to take $K(i)$ and $Q$ to be the identity matrices, $M(i) = M(i)$, and $P = N$.

The condition for $m = 0$ simply means (or in any event should be read to mean) that any $\Sigma$-colored matrix $N$ with entries in $A_n$ can be decomposed into a product $N = QP$ of two composable $\Sigma$-colored matrices $P$ and $Q$ with entries in $A_1$ and $A_{n-1}$, respectively. This is equivalent to the big graded ring $A$ being multiplicatively generated by $A_1$ over $A_0$.

The condition for $m = 1$ means that for any composable $\Sigma$-colored matrices $N$ and $M$ with entries in $A_n$ and $A_1$ such that $NM = 0$ there exist $\Sigma$-colored matrices $K$ with entries in $A_0$, $M'$ with entries in $A_1$, $P$ with entries in $A_1$, and $Q$ with entries in $A_{n-1}$ such that $M = KM'$, $NK = QP$, and $PM' = 0$. Together with the condition for $m = 0$, this clearly implies that $A$ is quadratic; the converse implication will follow from the argument below.

Let $G \supset E$, $E_0 \supset F$ denote the exact category with the additional data corresponding to the quadratic big graded ring $A$.

"If": we will show by induction on $n$ that $\text{Ext}_{\Sigma}^{n+1}(X, Y) = 0$ for all $X \in E_0$, $Y \in E_{n+m}$, and $m \geq 2$. The case $n = 1$ is known by (6.2); let $n \geq 2$. Suppose we are given a class in $\text{Ext}_{\Sigma}^{n+1}(X, Y)$; decompose it into a product of classes in $\text{Ext}_{\Sigma}^{1}(X, Z)$ and $\text{Ext}_{\Sigma}^{n}(Z, Y)$. As it was explained in Sections 3.2 and 6.1, one can assume that $Z \in G_{1,m}$. The sequence of classes in $\text{Ext}_{\Sigma}^{1}(X, q_1(Z))$, $\text{Ext}_{\Sigma}^{1}(q_1(Z), q_2(Z))$, $\ldots$, $\text{Ext}_{\Sigma}^{1}(q_{m-1}(Z), q_m(Z))$, coming from the class in $\text{Ext}_{\Sigma}^{1}(X, Z)$ and the filtered object $Z$ define a sequence of $\Sigma$-colored matrices $M(1), \ldots, M(m)$. The class in $\text{Ext}_{\Sigma}^{n}(q_m(Z), Y)$ coming from the class in $\text{Ext}_{\Sigma}^{n}(Z, Y)$ defines a matrix $N$. The existence of the object $Z$ and the classes in $\text{Ext}_{\Sigma}^{1}(X, Z)$ and $\text{Ext}_{\Sigma}^{n}(Z, Y)$ implies the equations on the products of consecutive matrices $M(i)$ and $N$. "
By assumption, it follows that there exist $\Sigma$-colored matrices $K_{(i)}$, $M'_{(i)}$, $P$, and $Q$ satisfying the equations of the theorem. Since $\text{Ext}^2_{\mathcal{G}}$ vanishes outside of the diagonal, starting from the matrices $M'_{(i)}$ one can construct [44] an object $Z' \in \mathcal{G}[1,m]$ and a class in $\text{Ext}^1_{\mathcal{G}}(X, Z')$ related to these matrices in the same way as the object $Z$ and the class in $\text{Ext}^1_{\mathcal{G}}(X, Z)$ are related to the matrices $M_{(i)}$. Since $\text{Ext}^1_{\mathcal{G}}$ also vanishes outside of the diagonal, starting from the matrices $K_{(i)}$ one can construct a morphism $Z' \to Z$ such that the original class in $\text{Ext}^1_{\mathcal{G}}(X, Z)$ comes from our new class in $\text{Ext}^1_{\mathcal{G}}(X, Z')$.

Consider the class in $\text{Ext}^2_{\mathcal{G}}(Z', Y)$ obtained by composing the morphism $Z' \to Z$ with the class in $\text{Ext}^2_{\mathcal{G}}(Z, Y')$. Then the related class in $\text{Ext}^2_{\mathcal{G}}(q_m(Z'), Y)$ can be decomposed into the product of classes in $\text{Ext}^1_{\mathcal{G}}(q_m(Z'), U)$ and $\text{Ext}^1_{\mathcal{G}}(U, Y)$ corresponding to the matrices $P$ and $Q$, where $U \in \mathcal{E}_{m+1}$. Due to the equation $PM'_{(m)} = 0$, the class in $\text{Ext}^2_{\mathcal{G}}(q_m(Z'), U)$ comes from a class in $\text{Ext}^1_{\mathcal{G}}(Z', U)$. Present the latter class by an exact triple $U \to T \to Z'$. The class in $\text{Ext}^1_{\mathcal{G}}(X, Z')$ comes from a class in $\text{Ext}^1_{\mathcal{G}}(X, T)$. Let us show that the composition of the morphism $T \to Z'$ with the class in $\text{Ext}^2_{\mathcal{G}}(Z', Y)$ vanishes. The image of that composition in $\text{Ext}^2_{\mathcal{G}}(T_{\geq m}, Y)$ is the composition of the morphism $T_{\geq m} \to q_m(Z')$ with the class in $\text{Ext}^2_{\mathcal{G}}(q_m(Z'), Y)$, which is clearly zero. So our class in $\text{Ext}^2_{\mathcal{G}}(T, Y)$ comes from a class in $\text{Ext}^2_{\mathcal{G}}(T_{\leq m-1}, Y)$. The latter class is zero by the assumption of induction on $n$.

"Only if": suppose that we are given $\Sigma$-colored matrices $M_{(i)}$, $m \geq 1$, and $N$ such that the consecutive pairs are composable with a zero product. As above, with the matrices $M_{(i)}$ one can associate an object $Z \in \mathcal{G}[1,m]$ and an extension class in $\text{Ext}^1_{\mathcal{G}}(X, Z)$ with $Z \in \mathcal{E}_0$; from the matrix $N$ one can obtain a class in $\text{Ext}^2_{\mathcal{G}}(q_m(Z), Y)$ with $Y \in \mathcal{E}_{n+m}$. The equation $NM_{(m)} = 0$ and the assumption of vanishing of $\text{Ext}^1_{\mathcal{G}}$ outside of the diagonal allow to conclude that the latter class comes from a class in $\text{Ext}^1_{\mathcal{G}}(Z, Y)$. By the same assumption, the product of these two classes vanishes in $\text{Ext}^{n+1}_\mathcal{G}(X, Y)$. By Lemma 4.4, there exists a morphism $Z' \to Z$ in $\mathcal{G}$ such that the class in $\text{Ext}^1_{\mathcal{G}}(X, Z')$ comes from a class in $\text{Ext}^1_{\mathcal{G}}(X, Z')$, while the induced class in $\text{Ext}^2_{\mathcal{G}}(Z', Y)$ vanishes. One can assume that $Z' \in \mathcal{G}[1,\infty]$.

The morphism $Z' \to Z$ factorizes as $Z' \to Z_{\leq m} \to Z$, and the induced class in $\text{Ext}^2_{\mathcal{G}}(Z_{\leq m}, Y)$ is the product of the class in $\text{Ext}^2_{\mathcal{G}}(Z'_{\leq m}, Z'_{\geq m+1})$ corresponding to $Z'$ and a certain class in $\text{Ext}^{n-1}_{\mathcal{G}}(Z'_{\geq m+1}, Y)$. By the same argument from Section 6.1 that was referred to above, one can assume that $Z'_{\geq m+1} \in \mathcal{E}_{m+1}$ and $Z' \in \mathcal{G}[1,m+1]$. It remains to construct matrices $M'_{(i)}$ from the object $Z'_{\leq m}$ and the class in $\text{Ext}^1_{\mathcal{G}}(X, Z'_{\leq m})$, matrices $K_{(i)}$ from the morphism $Z'_{\leq m} \to Z$, a matrix $P$ from the class in $\text{Ext}^1_{\mathcal{G}}(q_m(Z'), q_{m+1}(Z'))$, and a matrix $Q$ from the class in $\text{Ext}^{n-1}_{\mathcal{G}}(q_{m+1}(Z'), Y)$.

\[\text{Hom}_\mathcal{D}(X, Y[n]) = 0 \quad \text{for all } X \in \mathcal{E}_i, \ Y \in \mathcal{E}_j, \ n = 1, \text{ and } i \geq j, \text{ or } n \geq 2, \text{ and } n \neq j - i. \quad (7.2)\]
Furthermore, suppose that a triangulated autoequivalence $X \mapsto X(1)$ is defined on $\mathcal{D}$ such that $\mathcal{E}_i(1) = \mathcal{E}_{i+1}$. Let $\mathcal{M}$ denote the minimal full subcategory of $\mathcal{D}$, containing all $\mathcal{E}_i$ and closed under extensions.

Let $\mathcal{J} \subset \mathcal{E}_0$ be a full subcategory such that every object of $\mathcal{E}_0$ is a finite direct sum of objects of $\mathcal{J}$. Consider the big graded ring $A = (\text{Hom}_{\mathcal{D}}(X, Y(n)[n]))_{Y,X \in \mathcal{J}, n \geq 0}$.

**Theorem 7.4.** (1) The big graded ring $A$ is Koszul if and only if every morphism $X \to Y[n]$ of degree $n \geq 2$ in $\mathcal{D}$ between two objects $X,Y \in \mathcal{M}$ can be presented as the composition of a chain of morphisms $Z_{i-1} \to Z_i[1]$ with $Z_i \in \mathcal{M}$, $Z_0 = X$, and $Z_n = Y$ (cf. Appendix B).

(2) An arbitrary big graded ring $A$ is Koszul if and only if the following condition holds. Let $M_{(1)}, \ldots, M_{(m)}$, $m \geq 0$ be $\Sigma$-colored matrices with entries in $A_1$ such that every pair $(M_{(i+1)}, M_{(i)})$ is composable and the product $M_{(i+1)}M_{(i)}$ is zero. Let $N$ be a $\Sigma$-colored matrix with entries in $A_n$, $n \geq 1$, such that the pair $(N, M_{(m)})$ is composable and the product $NM_{(m)}$ is also zero. Then there should exist $\Sigma$-colored matrices $L_{(0)}, \ldots, L_{(m)}, M'_{(1)}, \ldots, M'_{(m)}$ with entries in $A_1$ and $Q$ with entries in $A_{n-1}$ such that

$$N = QL_{(m)}, \quad L_{(m)}M_{(m)} = M'_{(m)}L_{(m-1)}, \quad \ldots, \quad L_{(1)}M_{(1)} = M'_{(1)}L_{(0)},$$

$$M'_{(i+1)}M'_{(i)} = 0 \text{ for all } i = 1, \ldots, m-1, \text{ and } QM'_{(m)} = 0.$$ 

where all the pairs of matrices being multiplied are composable.

Notice that (2) provides a characterization of the Koszul property of a big graded ring $A$ that is explicitly independent of the component $A_0$ (since the condition for $n = 1$ is trivial, see below).

**Proof.** We will show that the decomposition condition in (1) holds for a triangulated category $\mathcal{D}$ and its full subcategory $\mathcal{M}$ if and only if the matrix condition in (2) is satisfied for the corresponding big graded ring $A$. Then it will remain to consider the triangulated category $\mathcal{D}$ and its exact subcategory $\mathcal{E}$ from the second proof in Section 6.2. By Corollary A.17, the decomposition condition for such $\mathcal{D}$ and $\mathcal{M} = \mathcal{E}$ is equivalent to the condition that the morphisms $\text{Ext}^p_\mathcal{E}(X, Y) \to \text{Hom}_{\mathcal{D}}(X, Y[n])$ be isomorphisms for all $X,Y \in \mathcal{E}$ and $n \geq 0$, and the latter is clearly equivalent to the condition (7.1) for the exact category $\mathcal{E}$.

As in Section 7.1, the condition for $n = 1$ is always trivial: it suffices to take $Q$ to be the identity matrix, $L_{(m)} = N$, $L_{(i)} = 0$ for $i < m$, and $M'_{(i)} = 0$ for all $i$. The condition for $m = 0$ should be read to mean that any $\Sigma$-colored matrix $N$ with entries in $A_0$ can be decomposed into a product $N = QL$, which is equivalent to $A$ being generated by $A_1$. The condition for $m = 1$ implies that $A$ has quadratic relations; the converse implication was essentially proven in Section 6 (see below for the details).

Suppose that the matrix condition in (2) holds. By Proposition B.1, it suffices to show that any element in $\text{Hom}_{\mathcal{D}}(X, Y[n])$ with $X \in \mathcal{M}$, $Y \in \mathcal{E}_0$, and $n \geq 2$ can be presented as the composition of an element in $\text{Hom}_{\mathcal{D}}(X, Z[1])$ and an element in $\text{Hom}_{\mathcal{D}}(Z, Y[n-1])$ with $Z \in \mathcal{M}$. As it was explained in Section 6.1, one can assume that $X \in \mathcal{M}_{(-\infty, -n]}$. Suppose that $X$ is a successive extension of objects $X_0, \ldots, X_m$, where $X_i \in \mathcal{E}_{-n-m+i}$. This means that there exist distinguished
triangles $X_i \to T_i \to T_{i-1} \to X_{i}[1]$ for all $1 \leq i \leq m$ such that $T_0 = X_0$ and $T_m = X$. Then the elements in $\text{Hom}_D(X_{i-1}, X_i[1])$ obtained as the compositions $X_{i-1} \to T_{i-1} \to X_i[1]$ provide matrices $M_{(i)}$ and the element in $\text{Hom}_D(X_m, Y[n])$ obtained as the composition $X_m \to X \to Y[n]$ provides a matrix $N$. The existence of the morphisms $T_i \to X_{i+1}[1]$ and $X \to Y[n]$ implies the equations on the products of consecutive matrices $M_{(i)}$ and $N$.

By assumption, it follows that there exist matrices $L_{(i)}$, $M'_{(i)}$, and $Q$ satisfying the equations of part (2). Let $Z_{i-1} \to Z_i[1]$, $i = 1, \ldots, m$, and $Z_m \to Y[n-1]$ be morphisms corresponding to the matrices $M'_{(i)}$ and $Q$, where $Z_i \in \mathcal{E}_{-n-m+i+1}$. Since $\text{Hom}_D(Z_i, Z_j[2]) = 0$ for $j-i > 2$, it follows from the equations $M'_{(i+1)}M'_{(i)} = 0$ that there exists a successive extension of objects $Z_i$ corresponding to our morphisms $Z_{i-1} \to Z_i$. In other words, there exist distinguished triangles $Z_i \to S_i \to S_{i-1} \to Z_i[1]$ for all $1 \leq i \leq m$ such that $S_0 = Z_0$ and the compositions $Z_{i-1} \to S_{i-1} \to Z_i[1]$ are equal to our morphisms $Z_{i-1} \to Z_i[1]$. Set $Z = S_m$. Since $\text{Hom}_D(Z_i, Y[n]) = 0$ for $i \leq m - 2$, it follows from the equation $QM'_{(m)} = 0$ that there exists a morphism $Z \to Y[n-1]$ making the triangle $Z_m \to Z \to Y[n-1]$ commutative. Finally, let $X_i \to Z_i[1]$ be the morphisms corresponding to the matrices $L_{(i)}$. Since $\text{Hom}_D(Z_i, X_j[2]) = 0$ for $j-i > 1$ and $\text{Hom}_D(X_i, Y[n+1]) = 0$ for $i \leq m-2$, it follows from the equations on the matrices $L_{(i)}$ that one can construct a morphism $X \to Z[1]$ making the triangle $X \to Z[1] \to Y[n]$ commutative.

Suppose that the decomposition condition in (1) holds. Let $M_{(i)}$, $m \geq 1$, and $N$ be $\Sigma$-colored matrices satisfying the equations $M'_{(i+1)}M_i = 0$ and $NM_{(m)} = 0$. As above, starting from these matrices one can construct a successive extension $X$ of objects $X_i \in \mathcal{E}_{-n-m+i}$ and a morphism $X \to Y[n]$. Decompose this morphism as $X \to Z[1] \to Y[n]$, where $Z \in \mathcal{M}$. By the argument from Section 6.1, one can assume $Z \in \mathcal{M}_{[-n-m+1, -n+1]}$. So the object $Z$ is a successive extension of objects $Z_i \in \mathcal{E}_{-n-m+i+1}$, $i = 0, \ldots, m$. Hence we obtain morphisms $Z_{i-1} \to Z_i[1]$. Since $\text{Hom}_D(X_i, Z_i[1]) = 0$ for $i > j$, one can obtain morphisms $X_i \to Z_i[1]$ from the morphism $X \to Z$. The composition $Z_m \to Z \to Y[n-1]$ provides a morphism $Z_m \to Y[n-1]$. These morphisms define the desired matrices $M'_{(i)}$, $L_{(i)}$, and $Q$. □

7.3. Flat case. Let $R$ be a big graded ring over a set $\Sigma$. A right $R$-module $N$ is called flat if the functor $M \mapsto N \otimes_R M$ is exact on the category of left $R$-modules. Flat left $R$-modules are defined in the similar way.

Let $A = A_0 \oplus A_1 \oplus A_2 \oplus \cdots$ be a big graded ring; set $R = A_0$. Assume that $A$ is quadratic. Consider the quadratic coring $C$ over $R$ defined in the first proof in Section 6.2. Introduce the reduced cobar-complex

$$R \to C_+ \to C_+ \otimes_R C_+ \to C_+ \otimes_R C_+ \otimes_R C_+ \to \cdots, \quad (7.3)$$

where $C_+ = C/J$; this complex is bigraded with the (cohomological) grading $n$ by the number of tensor factors and the (internal) grading $i$ induced by the grading of $C$.

**Theorem 7.5.** Let $A$ be a quadratic big ring such that either all the left $A_0$-modules $A_i$ are flat or all the right $A_0$-modules $A_i$ are flat. Then $A$ is Koszul if and only if the cobar-complex (7.3) has no cohomology outside of the diagonal $i + n = 0$. 

Proof. First of all let us show that it suffices only to consider the case when the right $A_\sigma$-modules $A_i$ are flat.

Lemma 7.6. Opposite big graded rings $A$ and $A^{op}$ are Koszul simultaneously.

Proof. It is clear that $A$ and $A^{op}$ are simultaneously quadratic; assume that they are. Let $\mathcal{G} \supset \mathcal{E}_i$, $\mathcal{E}_0 \supset \mathcal{J}$ be the exact category with the additional data corresponding to $A$. Consider the opposite exact category $\mathcal{G}' = \mathcal{G}^{op}$ with the full subcategories $\mathcal{E}'_i = \mathcal{E}_i^{op}$, the twist functor $X^{op}(-1) = X(-1)^{op}$, and the full subcategory $\mathcal{J}' = \mathcal{J}^{op} \subset \mathcal{E}'_0$. Then the exact category $\mathcal{G}' \supset \mathcal{E}'_i$, $\mathcal{E}_0' \supset \mathcal{J}'$ corresponds to $A^{op}$. Clearly, $\mathcal{G}$ and $\mathcal{G}'$ satisfy (7.1) simultaneously. □

It remains to notice that the coring $C^{op}$ over $R^{op}$ opposite to the coring $C$ corresponds to the quadratic ring $A^{op}$ in the same way as the coring $C$ corresponds to $A$, and the cobar-complexes (7.3) of $C$ and $C^{op}$ are isomorphic.

The rest of the proof is based on the following Lemmas 7.7–7.9.

Lemma 7.7. Let $C$ be a nonpositively graded coring over a big ring $R$ with $C_0 = R$. Then the embedding $\mathcal{G} \to \mathcal{H}$ of the exact category $\mathcal{G}$ of graded right $C$-comodules, free and finitely generated as graded $R$-modules, into the exact category $\mathcal{H}$ of $R$-flat graded right $C$-comodules induces an isomorphism of the groups $\text{Ext}^1$.

Proof. Clearly, it suffices to consider the categories $\mathcal{G}_{[0,m]}$ and $\mathcal{H}_{[0,m]}$ of graded $C$-comodules concentrated in the gradings $[0, m]$. We will show that the exact functor $\mathcal{G}_{[0,m]} \to \mathcal{H}_{[0,m]}$ satisfies the assumption of Lemmas 4.4–4.5. For this purpose we will use the big ring version of the Govorov–Lazard theorem that any flat module is a filtered inductive limit of finitely generated free modules. More precisely, we will need the fact that any morphism from a finitely presented $R$-module (i.e., the cokernel of a morphism of finitely generated free $R$-modules) to a flat $R$-module factorizes through a finitely generated free $R$-module. One proves this for modules over big rings in exactly the same way as in the case of conventional rings and modules; see [14, No. 1.5–6].

Let $T \to X$ be an admissible epimorphism in $\mathcal{H}_{[0,m]}$ onto an object $X \in \mathcal{G}_{[0,m]}$; we would like to construct an admissible epimorphism $Z \to X$ in $\mathcal{G}_{[0,m]}$ factorizable through the morphism $T \to X$. Proceed by induction on $m$, assuming that the morphisms $Z_{\leq m-1} \to T_{\leq m-1} \to X_{\leq m-1}$ have been constructed already. Let $Z_m'' \to T_m$ be a morphism into the grading component $T_m$ from a right finitely presented $R$-module $Z_m''$ such that the composition $Z_m'' \to T_m \to X_m$ is surjective and the compositions $Z_{m-1}'' \to T_{m-1} \to T_m \otimes_R C_{m-1}$ of the grading components of the morphism $Z_{\leq m-1} \to T_{\leq m-1}$ with the comultiplication maps $T_{m-1} \to T_m \otimes_R C_{m-1}$ factorize through the morphism $Z_m''' \otimes_R C_{m-1} \to T_m \otimes_R C_{m-1}$ for all $1 \leq i \leq m$. One can even easily choose $Z_m''$ to be a finitely generated free $R$-module.

Suppose the above factorizations of morphisms to be fixed. Let $Z_m''' \to Z_m''$ be a morphism of finitely presented $R$-modules through which the morphism $Z_m'' \to T_m$ factorizes such that the right $R$-module $Z_{\leq m-1} \oplus Z_m'''$ is a $C$-comodule, i.e., the coassociativity equations for the above maps $Z_{m-1}'' \to Z_m''' \otimes_R C_{m-1}$ together with the coaction maps of $Z_{\leq m-1}$ hold after taking the composition with the epimorphisms $Z_m''' \otimes_R C_{m-1} \to Z_m'' \otimes_R C_{m-1}$. It is clearly possible to find such finitely presented
$R$-module $Z''_m$, since there is only a finite number of equations on the tensor products of its elements that have to be satisfied. Now the morphism $Z''_m \to T_m$ between a finitely presented and a flat $R$-module factorizes through a finitely generated free $R$-module $Z'_m$. This provides a right $C$-comodule $Z'$, free and finitely generated as a right $R$-module, together with an epimorphism $Z' \to X$ factorizable through $T$. It remains to add to the comodule $Z'$ a direct summand, free and finitely generated over $R$ and concentrated in degree $m$, to obtain a morphism $Z \to X$ whose kernel is also a free and finitely generated $R$-module.

\[\]  

**Lemma 7.8.** Let $C$ be a graded coring over a big ring $R$ such that the components $C_i$ are flat right $R$-modules. Then for any $R$-projective graded right $C$-comodule $X$ and $R$-flat graded right $C$-comodule $Y$ the groups $\text{Ext}_C^3(X, Y)$ in the exact category $\mathcal{H}$ of $R$-flat graded right $C$-comodules are computed by the cobar-complex

$$\text{Hom}_R(X, Y) \to \text{Hom}_R(X, Y \otimes_R C_+) \to \text{Hom}_R(X, Y \otimes_R C_+ \otimes_R C_+) \to \cdots,$$

where $C_+ = \ker(C \to R)$, while the differentials are constructed in terms of the comultiplication in $C$ and the right coactions of $C$ in $X$ and $Y$.

**Proof.** Notice that our assertion does not depend on any positivity assumptions on the grading. The complex

$$Y \otimes_R C \to Y \otimes_R C_+ \otimes_R C \to Y \otimes_R C_+ \otimes_R C_+ \otimes_R C \to \cdots$$

is a right resolution of the graded right $C$-comodule $Y$ in the exact category $\mathcal{H}$. Actually, this resolution is even split over $R$. Its terms are $C$-comodules $V \otimes_R C$ coinduced from flat right $R$-modules $V$. One only has to check that such coinduced comodules are adjusted to the functor $\text{Hom}(X, -)$ on the exact category $\mathcal{H}$.

Indeed, the exact functor $V \mapsto V \otimes_R C$ from the category of flat right $R$-modules to the category of $R$-flat right $C$-comodules satisfies the dual version of the assumption of Lemmas 4.4–4.5. To check this, consider an admissible monomorphism $V \otimes_R C \to N$ in the category $\mathcal{H}$. Consider the morphism of $R$-modules $V \otimes_R C \to V$ induced by the counit of $C$. Let $K$ be the fibered coproduct of the $R$-modules $V$ and $N$ over $V \otimes_R C$, then $K$ is a flat right $R$-module and the morphism $V \to K$ is an admissible monomorphism of flat right $R$-modules. The morphism of right $R$-modules $N \to K$ induces a morphism of right $C$-comodules $N \to K \otimes_R C$, which forms a commutative triangle with the morphism $V \otimes_R C \to N$ and the morphism $V \otimes_R C \to K \otimes_R C$ coinduced from the admissible monomorphism $K \to V$.

Now since the exact triples of right $C$-comodules coinduced from exact triples of right $R$-modules remain exact after applying the functor $\text{Hom}_\mathcal{H}(X, -)$, one has $\text{Ext}_C^n(X, V \otimes_R C) = 0$ for $n > 0$.  

**Lemma 7.9.** Let $C' \to C$ be a morphism of nonpositively graded corings over a big ring $R$ such that the map $C'_{-i} \to C_{-i}$ is an isomorphism for $i < m$. Let $X$ and $Y$ be finitely generated free right $R$-modules placed in the gradings $0$ and $m$, respectively. Then the maps $\text{Ext}_C^n(X, Y) \to \text{Ext}_C^n(X, Y)$ between the Ext groups in the categories of right $C'$- and $C$-comodules, free and finitely generated as graded $R$-modules, are isomorphisms for $n \geq 3$.  

Proof. It is claimed that the groups $\text{Ext}^n_k(X, Y)$ for $n \geq 3$ only depend on the exact subcategories $\mathcal{G}_{[0, m-1]}$ and $\mathcal{G}_{[1, m]} \subset \mathcal{G}$. Indeed, any class in $\text{Ext}^n_k(X, Y)$ can be decomposed into the product of classes in $\text{Ext}^n_k(X, Z)$ and $\text{Ext}^{n-1}_k(Z, Y)$, where $Z \in \mathcal{G}_{[1, m-n+1]}$. The product of such two classes vanishes if and only if the class in $\text{Ext}^n_k(X, Z)$ is the composition of a class in $\text{Ext}^1(X, Z')$ and a morphism $Z' \to Z$, while the composition of the same morphism with the class in $\text{Ext}^{n-1}_k(Z, Y)$ vanishes. Moreover, one can choose $Z' \in \mathcal{G}_{[1, m-n+2]}$ (see the proof of Theorem 7.3, "Only if" part).

Let us finish the proof of Theorem 7.5. "If": the diagonal cohomology of the cobar-complex (7.3) can be easily identified with the components $A_i$. Knowing that $A_i$ are flat right $R$-modules and the cobar-complex has no cohomology outside of the diagonal, one shows by induction that the components $C_{-i}$ are flat $R$-modules, too. Then it remains to apply Lemmas 7.7–7.8.

"Only if": proceed by induction on the internal grading $m$. If the cohomology of the cobar-complex in the internal grading strictly above $-m$ are concentrated on the diagonal, then $C_{-i}$ are flat right $R$-modules for $i < m$. Consider the graded cobar $C'$ over $R$ with $C'_{-i} = C_{-i}$ for $i < m$ and $C'_{-i} = 0$ for $i \geq m$. It follows from Lemmas 7.7–7.9 that $\text{Ext}^n_k(X, Y)$ for $X \in \mathcal{E}_0$ and $Y \in \mathcal{E}_m$ for $n \geq 3$ can be computed in terms of the cobar-complex of the cobar $C$. Since we assume that these groups are zero for $n \neq m$, it follows that the cobar-complex has no cohomology outside of the diagonal in the internal grading $-m$.

Corollary 7.10. Let $k$ be a commutative ring and $A$ be a big graded ring with a $k$-algebra structure, i.e., the components $A_{m;i,n}$ are $k$-modules and the multiplications are $k$-linear. Let $S$ be a (conventional associative, not necessarily commutative) $k$-algebra. Assume that either $S$ is $k$-flat, or the components of $A$ are flat $k$-modules. Then the big graded ring $S \otimes_k A$ is Koszul whenever the big graded ring $A$ is Koszul. Assuming additionally that for any $k$-module $M$ the vanishing of $S \otimes_k M$ implies the vanishing of $M$, the converse implication also holds: $A$ is Koszul if $S \otimes_k A$ is.

Proof. Let us first consider the case when $S$ is $k$-flat. Then one can easily see that $S \otimes_k A$ is quadratic whenever $A$ is, and the converse also holds if $S$ is faithfully $k$-flat. The nonpositively graded cobar over $S \otimes_k A_0$ quadratic dual to $S \otimes_k A$ is naturally isomorphic to $S \otimes_k C$, where $C$ is the cobar quadratic dual to $A$. The category of graded right comodules over $S \otimes_k C$ is naturally identified with the category of graded right comodules over $C$ endowed with a right $S$-modules structure which agrees with the $k$-module structure and commutes with the coaction of $C$.

Let $\mathcal{H}_C$ and $\mathcal{H}_{S \otimes_k C}$ denote the exact categories of $A_0$-flat graded right $C$-comodules and $S \otimes_k A_0$-flat graded right $S \otimes_k A_0$-comodules. Then there is a natural exact functor $\mathcal{H}_{S \otimes_k C} \to \mathcal{H}_C$ of forgetting the action of $S$, which has an exact left adjoint functor $\mathcal{H}_C \to \mathcal{H}_{S \otimes_k C}$ sending a comodule $X$ to the comodule $S \otimes_k X$.

By [41, Lemma 2.1], there are natural isomorphisms

$$\text{Ext}^n_{\mathcal{H}_{S \otimes_k C}}(S \otimes_k A_0, S \otimes_k A_0(i)) \simeq \text{Ext}^n_{\mathcal{H}_C}(A_0, S \otimes_k A_0(i))$$
for all $n$ and $i$. By Lemma 7.7, the left hand side of this isomorphism is isomorphic to the similar group $\text{Ext}^i_S(X, S)$ free and finitely generated as $S$-modules.

By Lemma 4.5, which is applicable according to the proof of Lemma 7.7, the right hand side is isomorphic to $S \otimes_k S$. Indeed, one readily checks that for any object $X$ of the exact category $\mathcal{G}_C$ of right $C$-comodules, free and finitely generated as $A_0$-modules, and any object $Y \in \mathcal{H}_C$, there is a natural isomorphism $\text{Hom}_{\mathcal{H}_C}(X, S \otimes_k Y) \simeq S \otimes_k \text{Hom}_{\mathcal{H}_C}(X, Y)$, since there is a similar isomorphism for morphisms of graded $A_0$-modules and $S$ is $k$-flat. This proves the desired assertion.

The case when $A$ is $k$-flat is easily dealt with using the condition (c) from Theorem 7.12 below. □

When $k$ is an Artinian local commutative ring and $S = f$ is its residue field, a stronger assertion holds. Namely, if $A$ is quadratic and $A_\alpha$ is $k$-flat for $n = 1, 2$, and 3, then Koszulity of $f \otimes_k A$ implies Koszulity of $A$ and $k$-flatness of $A_\alpha$ for all $n \geq 1$. The proof is similar to that of [34, Theorem 7.3 of Chapter 6].

7.4. Generalities on flat Koszulity. Recall the definition of a quadratic big graded ring from Section 6.1 and the definitions of a quadratic coring and the quadratic duality from the first proof in Section 6.2.

Let $C = C_0 \oplus C_{-1} \oplus C_{-2} \oplus \cdots$ be a graded coring over a big ring $R$ such that $C_0 = R$. Let $\mathcal{G}$ denote the exact category of graded right $C$-comodules that are free and finitely generated as graded right $R$-modules, and let $\mathcal{H}$ be the category of graded right $C$-comodules that are flat as graded right $R$-modules.

Let $\text{Ext}^n_C(R, R(m))$ and $\text{Ext}^m_C(R, R(n))$ denote the $R$-bimodules whose components $\text{Ext}^n_C(R, R(m))_{\sigma \tau}$ are the groups $\text{Ext}^n_R$ in the categories $\mathcal{G}$ and $\mathcal{H}$ between the free right $R$-modules with one generator placed in the gradings 0 and $m$.

**Theorem 7.11.** The following conditions are equivalent:

(a) $\text{Ext}^n_C(R, R(m)) = 0$ for all $n \neq m$ and $\text{Ext}^n_C(R, R(n))$ is a flat right $R$-module for all $n$;

(b) $\text{Ext}^n_C(R, R(m)) = 0$ for all $n \neq m$ and $\text{Ext}^n_C(R, R(n))$ is a flat right $R$-module for all $n$;

(c) the coher-complex (7.3) has no cohomology outside of the diagonal $i + n = 0$, and its cohomology on this diagonal are flat right $R$-modules;

(d) the coring $C$ is quadratic, and for any $m \geq 1$ the lattice of subbimodules of the $R$-bimodule $C_1 \otimes_R C_m$ generated by the subbimodules $C_1 \otimes_R C_{m-j}$, $1 \leq j \leq m-1$, is distributive and the quotient bimodule for any pair of embedded bimodules in this lattice is a flat right $R$-module.

Let $A = A_0 \oplus A_1 \oplus A_2 \oplus \cdots$ be a big graded ring with the zero-degree component $A_0 = R$. Consider the reduced bar-complex

$$R \leftarrow A_+ \leftarrow A_+ \otimes_R A_+ \leftarrow A_+ \otimes_R A_+ \otimes_R A_+ \leftarrow \cdots,$$  \hspace{1cm} (7.4)
For a left $A$-module $M$ and a right $A$-module $N$, let $\text{Tor}_n^A(N, M)$ denote the derived functor of tensor product of $A$-modules. The groups $\text{Tor}_n^A(N, M)$ inherit the internal grading of $M$, $N$, and $A$.

**Theorem 7.12.** Assume that the components $A_i$ are flat right $R$-modules. Then the following conditions are equivalent:

(a) the graded abelian group $\text{Tor}_n^A(N, M)$ is concentrated in degree $n$ for any finitely generated free (left and right) $R$-modules $M$ and $N$ considered as graded $A$-modules concentrated in degree 0;

(b) the graded abelian group $\text{Tor}_n^A(N, M)$ is concentrated in degree $n$ for any left $R$-module $M$ and any flat right $R$-module $N$ considered as graded $A$-modules concentrated in degree 0;

(c) the bar-complex (7.4) has no cohomology outside of the diagonal $i = n$;

(d) the big ring $A$ is quadratic with the $R$-bimodule of quadratic relations $I \subset A_1 \otimes_R A_1$, and for any $m \geq 1$ the lattice of subbimodules of the $R$-bimodule $A_1 \otimes^m \otimes_R I \otimes_R A_1^{(m-j-1)}$, $1 \leq j \leq m - 1$, is distributive.

Suppose a quadratic big ring $A$ and a quadratic coring $C$ are quadratic dual to each other. Consider the tensor products $A \otimes_R C$ and $C \otimes_R A$; they are endowed with the differentials constructed as the composition $A_i \otimes_R C_{-j} \rightarrow A_i \otimes_R C_{-1} \otimes_R C_{-j+1} \simeq A_i \otimes_R A_1 \otimes_R C_{-j+1} \rightarrow A_{i+1} \otimes_R C_{-j+1}$ of the comultiplication and the multiplication maps, and analogously for $C \otimes_R A$. Define the internal grading on $A \otimes_R C$ and $C \otimes_R A$ by the rule that the component $A_i \otimes_R C_{-j}$ or $C_{-j} \otimes_R A_i$ lives in the grading $i+j$.

The complexes $A \otimes_R C$ and $C \otimes_R A$ are called the Koszul complexes of the quadratic dual big ring $A$ and coring $C$.

**Corollary 7.13.** The following conditions are equivalent:

(A) the big graded ring $A$ satisfies the equivalent conditions of Theorem 7.11;

(B) the graded coring $C$ satisfies the equivalent conditions of Theorem 7.12;

(C) the components $A_i$ are flat right $R$-modules and either of the Koszul complexes $A \otimes_R C$ or $C \otimes_R A$ is exact in the internal grading $m \geq 1$.

A big graded ring $A$ or a graded coring $C$ is called right flat Koszul if it satisfies the equivalent conditions of Theorem 7.12 or Theorem 7.11, respectively. According to the corollary, quadratic dual quadratic big ring and quadratic coring are Koszul simultaneously. Notice that our terminology is consistent: if $A$ is a big graded ring whose components $A_i$ are flat right $A_0$-modules, then $A$ is right flat Koszul in the sense of the above definition if and only if it is Koszul in the sense of the definition given in the beginning of Section 7. To see this, it suffices to compare Theorem 7.5 with Theorem 7.11(c) and use Corollary 7.13.

**Proof of Theorems 7.11–7.12 and Corollary 7.13.** It was explained in Section 7.3 how to prove the equivalence of (a), (b), and (c) in Theorem 7.11. Proving the equivalences (a) ⇔ (c) and (b) ⇔ (c) in Theorem 7.12 is easy, since one can compute the Tor in terms of the bar-complex. To prove the equivalence of (c) and (d) in both theorems, one can use Lemma 1 and the big ring version of Lemma 2(a) from [38,
Section 11.4.3. This also allows to prove the equivalence of (A) and (B) in the corollary and deduce (C) from (A–B). Finally, to pass from (C) of the corollary to Theorem 7.12(a) one simply uses the Koszul complex as a resolution of free (left or right) \( R \)-modules considered as \( A \)-modules concentrated in degree 0. □

**Remark 7.14.** When one is thinking of the conditions (a–b) of Theorem 7.12, one keeps in mind that for any nonnegatively graded ring \( A \) whose components are flat right \( R \)-modules, the graded abelian groups \( \text{Tor}^A_n(N, M) \) are concentrated in degrees \( \geq n \). Without the flatness condition, this is no longer true. For a counterexample, it suffices to consider a field \( k \), the ring of polynomials in one variable \( R = k[x] \), and the graded commutative ring \( A = k[x, y]/(xy) \) with \( \deg x = 0 \) and \( \deg y = 1 \). Another example is the graded ring \( B \) over \( R = \mathbb{Z} \) with \( B_0 = \mathbb{Z} \), \( B_1 = \mathbb{Q}/\mathbb{Z} \), and \( B_n = 0 \) for \( n \geq 2 \). The graded ring \( B \) is Koszul (see Example 7.2). To compute \( \text{Tor}^B_\ast(Z, Z) \) one can replace \( B \) with its flat graded DG-algebra resolution over \( \mathbb{Z} \) and write down the bar-complex of the resolution. Hence one finds that the graded group \( \text{Tor}^B_n(Z, Z) \) vanishes for even \( n \geq 2 \) and is isomorphic to the group \( \mathbb{Q}/\mathbb{Z} \) placed in the degree \( (n + 1)/2 \) for odd \( n \geq 1 \). Of course, one can still use the reduced bar-complex (7.4) to compute the \( \text{Tor} \) over \( A \) relative to \( R \) in the nonflat case, so the relative \( \text{Tor} \) is concentrated in the usual degrees.

**Remark 7.15.** Let \( A = R \oplus A_1 \oplus A_2 \oplus \cdots \) be a nonnegatively graded ring and \( S \to R \) be a morphism of rings such that \( A_i \) are flat right \( R \)-modules and flat right \( S \)-modules for all \( i \geq 1 \). Then it follows from our results that the graded rings \( A \) and \( B = S \oplus A_1 \oplus A_2 \oplus \cdots \) satisfy the conditions of Theorem 7.12 simultaneously. This can be proved directly in several ways. In particular, one can use the spectral sequence \( E_{pq}^2 = \text{Tor}^A_p(\text{Tor}^B_q(S, A), R) \Rightarrow \text{Tor}^B_{p+q}(S, R) \) corresponding to the morphism of rings \( B \to A \). There is also a simple lattice-theoretical argument.

### 8. Nonfiltered Exact Categories

For any big graded ring \( A = A_0 \oplus A_1 \oplus A_2 \oplus \cdots \), denote by \( quA \) the “quadratic part” of \( A \), i.e., the quadratic ring for which there is a natural morphism of big graded rings \( quA \to A \) that is an isomorphism in degrees \( n = 0 \) and \( 1 \), and a monomorphism in degree \( n = 2 \).

The following set of stronger assumptions on the morphism \( quA \to A \) and the big graded ring \( quA \) will play the key role in this section:

- the natural morphism \( quA \to A \) is an isomorphism in degree \( n = 2 \) and a monomorphism in degree \( n = 3 \); (8.1)
- the quadratic big ring \( quA \) is Koszul. (8.2)

Let \( \mathcal{E} \) be an exact category, \( \mathcal{E}_0 \) be a small additive category, and \( \Phi_0 : \mathcal{E}_0 \to \mathcal{E} \) be a fully faithful additive functor. Consider the category \( \mathcal{E}_0 \) as an exact category with the trivial exact category structure and use the construction of Example 4.1 to obtain an exact category \( \mathcal{F} \) with full subcategories \( \mathcal{E}_i \) and a twist functor \( X \mapsto X(1) \). Let \( \Phi : \mathcal{F} \to \mathcal{E} \) denote the forgetful functor.
Let \( \mathcal{J} \subseteq \mathcal{E}_0 \) be a full subcategory such that every object of \( \mathcal{E}_0 \) is a finite direct sum of objects from \( \mathcal{J} \). Consider the big graded ring \( A = (\text{Ext}^i_\mathcal{E}(X, \Phi(Y)))_{Y, X \in \mathcal{J}, n \geq 0} \) over the set \( \text{Ob} \mathcal{J} \).

**Proposition 8.1.** Assume that the big graded ring \( A \) satisfies (8.1–8.2). Then the natural maps \( \text{Ext}^i_\mathcal{E}(X, Y(m)) \to \text{Ext}^i_\mathcal{E}(X, Y(m + 1)) \) are isomorphisms for all \( X, Y \in \mathcal{E}_0 \) and \( n \leq m \), and the big graded ring \( (\text{Ext}^i_\mathcal{E}(X, Y(n)))_{Y, X \in \mathcal{J}, n \geq 0} \) is isomorphic to \( \text{qu} A \).

**Proof.** The case \( n = 0 \) is clear. According to part (2) of Theorem 3.1, the morphisms \( \text{Ext}^i_\mathcal{E}(X, Y(m)) \to \text{Ext}^i_\mathcal{E}(X, Y(m + 1)) \) are isomorphisms for \( X, Y \in \mathcal{E}_0 \) and \( m \geq n = 1 \), and monomorphisms for \( m \geq n = 2 \). The former observation proves both assertions of the proposition for \( n = 1 \).

By the result of Section 6.1, one has \( \text{Ext}^i_\mathcal{E}(X, Y(m)) = 0 \) for \( n > m \) and the big graded ring \( (\text{Ext}^i_\mathcal{E}(X, Y(n)))_{Y, X \in \mathcal{J}, n \geq 0} \) is quadratic. This establishes the second assertion in all degrees. We have not yet used the assumptions (8.1–8.2) so far.

Since by the assumption (8.1) the component \( A_2 \) is multiplicatively generated by \( A_1 \), the first assertion of the proposition for \( n = 2 \) also follows.

Now consider the exact category \( \mathcal{G} \) constructed in Section 4. From the long exact sequence (4.5) we see that \( (\text{Ext}^n_\mathcal{G}(X, Y(n)))_{Y, X \in \mathcal{J}, n \geq 0} \simeq \text{qu} A \), \( \text{Ext}^1_\mathcal{G}(X, Y(m)) = 0 \) for \( m \geq 2 \), and \( \text{Ext}^0_\mathcal{G}(X, Y(3)) = 0 \).

Let us prove by induction that \( \text{Ext}^2_\mathcal{G}(X, Y(m)) = 0 \) for \( m \geq 4 \). Assume that \( \text{Ext}^2_\mathcal{G}(X, Y(j)) = 0 \) for \( 3 \leq j \leq m - 1 \). Let \( \mathcal{G}' \) denote the exact category from Section 6.2 corresponding to the quadratic ring \( \text{qu} A \). Then the exact subcategories \( \mathcal{G}'[0, m-1] \) and \( \mathcal{G}'[0, m-1] \) are naturally equivalent. Since the ring \( \text{qu} A \) is Koszul, one has \( \text{Ext}^2_\mathcal{G'}(X, Y(i)) = 0 \) for \( n \neq i \). Hence \( \text{Ext}^2_\mathcal{G}(X, Y(j)) = 0 \) for \( 4 \leq j \leq m - 1 \).

Consequently, the map \( \text{Ext}^2_\mathcal{G}(X, Y(3)) \to \text{Ext}^2_\mathcal{G}(X, Y(m-1)) \) is an isomorphism. By the assumption (8.1), the map \( \text{Ext}^2_\mathcal{G}(X, Y(3)) \to \text{Ext}^2_\mathcal{G}(X, Y(3)) \) is a monomorphism. It follows that the map \( \text{Ext}^2_\mathcal{G}(X, Y(m-1)) \to \text{Ext}^2_\mathcal{G}(X, Y(m)) \) is a monomorphism, too. Thus \( \text{Ext}^2_\mathcal{G}(X, Y(m)) = 0 \).

Now since \( \text{qu} A \) is Koszul, we have \( \text{Ext}^2_\mathcal{G}(X, Y(m)) = 0 \) for all \( n \neq m \), hence the map \( \text{Ext}^2_\mathcal{G}(X, Y(m-1)) \to \text{Ext}^2_\mathcal{G}(X, Y(m)) \) is an isomorphism for all \( n < m \).

**Lemma 8.2.** In the above setting, assume that every object of \( \mathcal{E} \) can be obtained from objects of \( \Phi_0(\mathcal{E}_0) \) by iterated extensions. Then the natural maps

\[
\lim_{\substack{\rightarrow \\ m}} \text{Ext}^2_\mathcal{E}(X, Y(m)) \to \text{Ext}^2_\mathcal{E}(\Phi(X), \Phi(Y))
\]

are isomorphisms for all \( X, Y \in \mathcal{F} \) and \( n \geq 0 \).

**Proof.** The cases \( n = 0 \) and 1 are easy and do not depend on the assumption of the lemma. To check surjectivity of our maps for all \( n \), it suffices to notice that the functor \( \Phi \) is surjective on objects. One can use Corollary A.16 to prove both surjectivity and injectivity. Alternatively, use Lemma 4.5 for the functor \( \Phi \), which satisfies its assumption. This argument does not depend on the assumption that the exact category structure on \( \mathcal{E}_0 \) is trivial. When it is, one can additionally notice that all the maps \( \text{Ext}^2_\mathcal{E}(X, Y(m)) \to \text{Ext}^2_\mathcal{E}(X, Y(m+1)) \) constituting our inductive systems are injective for \( n \leq 2 \). \( \square \)
Example 8.3. The following example was suggested to the author by A. Beilinson. Consider the case when the functor $\Phi$ is an equivalence of additive categories. Then the natural maps $\text{Ext}^2_{\mathcal{E}}(X, Y(m)) \rightarrow \text{Ext}^2_{\mathcal{E}}(\Phi(X), \Phi(Y))$ are isomorphisms for all $X, Y \in \mathcal{E}_0$ and $n \leq m$. Indeed, present any class in $\text{Ext}^2_{\mathcal{E}}(\Phi(X), \Phi(Y))$ as the composition of a chain of classes in $\text{Ext}^1_{\mathcal{E}}(T_{i-1}, T_i)$ with $T_i \in \mathcal{E}$, $Z_0 = \Phi(X)$, and $T_n = \Phi(Y)$. For all $1 \leq i \leq n - 1$, choose objects $Z_i \in \mathcal{E}_i$ so that $T_i = \Phi(Z_i)$; set $Z_0 = X$ and $Z_n = Y(m)$. Clearly, there are unique classes in $\text{Ext}^1_{\mathcal{E}}(Z_{i-1}, Z_i)$ lifting the given classes in $\text{Ext}^1_{\mathcal{E}}(T_{i-1}, T_i)$. The product of these classes provides a class in $\text{Ext}^2_{\mathcal{E}}(X, Y(m))$. One checks that this construction defines a map $\text{Ext}^2_{\mathcal{E}}(\Phi(X), \Phi(Y)) \rightarrow \text{Ext}^2_{\mathcal{E}}(X, Y(m))$ inverse to the natural map that we are interested in. Using the construction of the exact category $\mathcal{G}$ from Section 4 and the long exact sequence (4.5) (cf. Section 9.1), one can conclude that the big graded ring $A = (\text{Ext}^2_{\mathcal{E}}(X, Y))_{Y, X \in \mathcal{J}, n \geq 0}$ is Koszul.

Let $\mathcal{E}$ be a small exact category and $\mathcal{J} \subset \mathcal{E}$ be a full subcategory such that every object of $\mathcal{E}$ can be obtained from objects of $\mathcal{J}$ by iterated extensions. Consider the big graded ring $A = (\text{Ext}^2_{\mathcal{E}}(X, Y))_{Y, X \in \mathcal{J}, n \geq 0}$ over the set $\text{Ob} \mathcal{J}$.

The following theorem is a far-reaching generalization of the main result of [42].

Theorem 8.4. Assume that the big graded ring $A$ satisfies the assumptions (8.1–8.2). Then $A$ is quadratic (and consequently, Koszul).

Proof. Consider the full additive subcategory $\mathcal{E}_0 \subset \mathcal{E}$ consisting of the finite direct sums of objects from $\mathcal{J}$, and apply Proposition 8.1 and Lemma 8.2. □

Let $\mathcal{D}$ be a triangulated category and $\mathcal{E} \subset \mathcal{D}$ be a full exact subcategory closed under extensions (see Section A.8). Let $\mathcal{J} \subset \mathcal{E}$ be a full subcategory such that every object of $\mathcal{E}$ can be obtained from objects of $\mathcal{J}$ by iterated extensions.

In addition to the above big graded ring $A$, consider the big graded ring $B = (\text{Hom}_{\mathcal{D}}(X, Y[n]))_{Y, X \in \mathcal{J}, n \geq 0}$ over the same set $\text{Ob} \mathcal{J}$.

The following corollary generalizes the results of [36, Section 5].

Corollary 8.5. Assume that the big graded ring $B$ satisfies (8.1–8.2). Then the natural morphism $A \rightarrow B$ induces an isomorphism of big graded rings $A \simeq \text{qu} B$. In particular, if the big graded ring $B$ is Koszul, then $A \simeq B$ and the natural morphisms $\text{Ext}^2_{\mathcal{E}}(X, Y) \rightarrow \text{Hom}_{\mathcal{D}}(X, Y[n])$ are isomorphisms for all $X, Y \in \mathcal{E}$ and $n \geq 0$.

Proof. By Corollary A.17, the morphism $A \rightarrow B$ is an isomorphism in the degrees 0 and 1 and a monomorphism in the degree 2. It follows that $\text{qu} A \simeq \text{qu} B$ and $A$ satisfies (8.1–8.2) whenever $B$ does. If this is the case, $A$ is quadratic by Theorem 8.4, hence $A \simeq B$. If $B$ is also quadratic, then $A \simeq B$ and induction by the number of iterated extensions proves the last assertion of the corollary. □

One can easily extend Lemma 8.2, Theorem 8.4, and Corollary 8.5 to the situation when every object of $\mathcal{E}$ is a direct summand of an object obtained from objects of $\mathcal{J}$ (resp. $\mathcal{E}_0$) by iterated extensions. It suffices to use Corollary A.18.
9. Conclusions and Epilogue

9.1. Main theorem. Let $D$ be a triangulated category and $E_i \subset D$ be its full subcategories, closed under extensions and such that

$$\text{Hom}_D(X, Y[n]) = 0 \quad \text{for} \quad X \in E_i, \quad Y \in E_j, \quad n \geq -1, \quad \text{and} \quad n > j - i. \quad (9.1)$$

Let $E$ be an exact category and $\Phi: D \to D(E)$ be a triangulated functor mapping $E_i$ into $E$. Assume that

the induced morphisms $\text{Hom}_D(X, Y[n]) \to \text{Ext}^n_E(X, Y)$

are isomorphisms for all $X \in E_i, \quad Y \in E_j, \quad n \geq -1, \quad \text{and} \quad n \leq j - i. \quad (9.2)$

Finally, assume that there exists a triangulated autoequivalence $X \mapsto X(1)$ on $D$ such that $E_i(1) = E_i + 1$ and there is a functorial isomorphism $\Phi(X(1)) \cong \Phi(X)$ for all $X \in D$.

Let $M$ be the minimal full subcategory of $D$, containing all $E_i$ and closed under extensions; by [18] or Section A.8, $M$ has a natural structure of exact category.

Let $J \subset E_0$ be a full subcategory such that every object of $E_0$ is a finite direct sum of objects of $J$. Consider the big graded ring $A = (\text{Ext}^n_E(\Phi(X), \Phi(Y)))_{Y, X \in J; \ n \geq 0}$.

Theorem 9.1. The natural morphisms $\text{Ext}^n_M(X, Y) \to \text{Hom}_D(X, Y[n])$ are isomorphisms for all $X, Y \in M$ and $n \geq 0$ if and only if the big graded ring $A$ is Koszul.

Proof. By part (1) of Theorem 3.1, the exact category $M$ is equivalent to the exact category $\mathcal{F}$ constructed in Example 4.1 for the trivial exact category structure on $E_0$. Now the “if” part follows from Proposition 8.1. To prove “only if”, it suffices to consider the exact category $\mathcal{G}$ constructed in Section 4. It follows from the long exact sequence (4.5) that $\text{Ext}^n_M(X, Y) = 0$ for all $X \in E_i, \ Y \in E_j$, and $n \neq j - i$, and that the big graded ring $(\text{Ext}^n_M(X, Y(n)))_{Y, X \in J; \ n \geq 0}$ can be identified with $A$. Thus $A$ is Koszul. □

9.2. Main conjecture. Let $k = \mathbb{Z}, \mathbb{Q}, \mathbb{Z}[m^{-1}]$, or $\mathbb{Z}/m$, $m \geq 2$, be a coefficient ring and $K$ be a field. In the remaining part of this paper we discuss conjectural properties of certain subcategories of the triangulated category $\text{DM}(K, k)$ of motives over $K$ with coefficients in $k$.

A few words about the definition of $\text{DM}(K, k)$ are due. We are not in a position to discuss various definitions of the triangulated category of motives existing in the literature, so we simply presume that the category we are considering is the “right” triangulated category. Voevodsky’s definition [49] is certainly a good approximation, as it is very natural and has many properties that are important for us. However, their proofs sometimes depend on various undesirable assumptions, such as that the field $K$ is perfect, has finite étale dimension over $k$, or has resolution of singularities. Other known definitions have some other properties that are also important for us [20]. In the course of our discussion, we refer to various results as to indicators of the properties that the “right” category is supposed to have.

Let $M/K$ be a Galois field extension. Consider the full triangulated subcategory $D \subset \text{DM}(K, k)$ generated by the Artin–Tate motives $k[L](i)$, where $k[L]$ are the
motives of finite field extensions $L/K$ contained in $M$, and $X \mapsto X(i)$, $i \in \mathbb{Z}$, denotes the Tate twist. Let $\mathcal{M}$ be the minimal full subcategory of $\mathcal{D}$, containing the objects $k[L](i)$ and closed under extensions.

**Conjecture 9.2.** Any morphism $X \to Y[n]$ of degree $n \geq 2$ in $\mathcal{D}$ between two objects $X, Y \in \mathcal{M}$ can be presented as the composition of a chain of morphisms $Z_{i-1} \to Z_i[1]$ with $Z_i \in \mathcal{M}$, $Z_0 = X$, and $Z_n = Y$.

By Propositions B.2, B.4, B.6, this conjecture can be equivalently restated as follows:

$$\mathcal{D} = \bigcup_{a \leq b \in \mathbb{Z}} \mathcal{M}[-b] * \cdots * \mathcal{M}[-a],$$

where $*$ denotes the class of all extensions of objects from two given classes in a triangulated category [4, 1.3.9–10]. Iterated extensions of this form generalize silly filtrations on complexes; thus the above conjecture can be called the silly filtration conjecture for Artin–Tate motives.

**9.3. Elementary construction for finite coefficients.** Consider the case when $k = \mathbb{Z}/m$ and char $K$ is prime to $m$. In this case, there is the étale realization functor $\Phi$ [49, Section 3.3] (see also [23]) from $\mathcal{D}\mathcal{M}(K, k)$ to the derived category $\mathcal{D}(\mathcal{E})$ of the abelian category $\mathcal{E}$ of discrete $G_K$-modules over $\mathbb{Z}/m$, where $G_K$ is the absolute Galois group of $K$. The functor $\Phi$ takes the object $k[L](i)$ to the $G_K$-module $\mu_m^{\text{cycl}}[G_K/G_L]$, where $\mu_m \subset K$ is the module of $m$-roots of unity.

The Milnor–Bloch–Kato conjecture implies [46], [21] the Beilinson–Lichtenbaum formulas

$$\text{Hom}_\mathcal{D}(k[L'](i), k[L''(j)|n]) \simeq \text{Ext}^2_{\mathcal{E}}(\Phi(k[L'](i)), \Phi(k[L''(j)])), \quad \text{for } \leq j - i;$$

$$\text{Hom}_\mathcal{D}(k[L'](i), k[L''(j)|n]) = 0, \quad \text{otherwise.}$$

(9.3)

Assuming (9.3), by part (1) of Theorem 3.1 the exact subcategory $\mathcal{M} \subset \mathcal{D}$ is equivalent to the exact category $\mathcal{F}$ of filtered discrete $G_K$-modules $(N, F)$ over $\mathbb{Z}/m$ with a finite decreasing filtration $F$ such that the $G_K$-module $F^i N/F^{i+1} N$ is isomorphic to a direct sum of copies of “cyclotomic-permutational” $G_K$-modules $\mu_m^{\text{cycl}}[G_K/G_L]$, where $L/K$ are finite extensions, $K \subset L \subset M$. By the results of Appendix D, this equivalence can be extended to a triangulated functor $\Theta: \mathcal{D}^\text{B}(\mathcal{F}) \to \mathcal{D}$.

The main conjecture from Section 9.2 holds for $k$ and $K \subset M$ if and only if the functor $\Theta$ is an equivalence of triangulated categories. This provides an elementary description of the triangulated category $\mathcal{D}$ in terms of the Galois group $G_K$, solving (for Artin–Tate motives over a field) the problem posed in [2, Section 5.10.D(vi)].

**Remark 9.3.** Notice that even when $M = K$ is algebraically/nn separably closed, the category of “cyclotomic-permutational” $G_K$-modules is still substantially different from the category of all discrete $G_K$-modules over $k$, as there are many discrete $G_K$-modules that are not direct summands of permutational ones. Ignoring this difference, one could consider the exact category $\mathcal{F}'$ of all finitely filtered discrete $G_K$-modules over $k$, with exact triples that become split after passing to associated graded $G_K$-modules. For the exact category $\mathcal{F}'$, the Beilinson–Lichtenbaum formulas always hold (see Example 8.3) and no additional hypotheses are needed.
9.4. Diagonal cohomology. The supporting evidence for Conjecture 9.2 that we possess is based on the properties of the big graded ring

\[ A = (\text{Hom}_D(k[L'], k[L''(n)][n]))_{K \subseteq L'' \subseteq M} \]  

over the set of all (isomorphism classes over \( K \)) intermediate fields \( K \subseteq L \subseteq M \) finite over \( K \). When the extension \( M/K \) is finite, one can equivalently consider the conventional graded ring (0.2).

By [46, Theorem 3.4], the \( k \)-module \( \text{Hom}_D(k[L'], k[L''(n)][n]) \) is isomorphic to the direct sum of the degree-\( n \) components of Milnor K-theory rings \( K_M^n(N) \) over the field direct summands \( N \) of the tensor product \( L' \otimes_K L'' \). The multiplication in \( A \) is described in terms of the multiplications in the Milnor rings and the maps of inclusion and transfer between the Milnor rings induced by morphisms of fields over \( K \).

According to Theorem 6.1, it follows from the conjecture that the (big) graded ring \( A \) is quadratic. In the case of Tate motives, i.e., when \( K = M \), this is obviously so, since the Milnor K-theory ring is quadratic by definition. In the general case of Artin–Tate motives, it is not difficult to see that the (big) graded ring \( A \) is multiplicatively generated by \( A_1 \) over \( A_0 \). In fact, it is only essential that the set of all fields \( L/K \) entering into the definition of \( A \) is closed under the operation of taking the composite extensions. For further evidence, see Sections 9.5 and 9.8, and also [40].

9.5. Koszul cases. Let us consider the three “Koszul” cases (i–iii) from Section 0.10 one by one.

When \( k = \mathbb{Q} \) and char \( K = p \neq 0 \), the Beilinson–Parshin conjecture [19] predicts that \( \text{Hom}_D(k[L'], k[L''(i)][n]) = 0 \) for \( i \neq n \). By part (1) of Theorem 7.4, it follows that Conjecture 9.2 holds if and only if the (big) graded ring \( A \) is Koszul in the sense of the definition given in the beginning of Section 7.

Similarly, when \( k = \mathbb{Z}/p^r \) and char \( K = p \), it is known [20] that \( \text{Hom}_D(k[L'], k[L''(i)][n]) = 0 \) for \( i \neq n \). Again, it follows that Conjecture 9.2 holds if and only if the (big) graded ring \( A \) is Koszul in the sense of the beginning of Section 7.

Finally, when \( k = \mathbb{Z}/m \) and \( K \) contains a primitive \( m \)-root of unity, the étale realization functor \( \Phi \) transforms the twist functor \( X \mapsto X(1) \) on \( D(E) \) to the identity functor on \( D(E) \), so the conditions of Section 9.1 are satisfied. Assuming (9.3), by Theorem 9.1 (and the last assertion of Corollary A.17) it follows that Conjecture 9.2 holds if and only if the (big) graded ring \( A \) is Koszul in the same sense.

In any of the above three cases, in order to interpret the Koszulity condition, one can replace the component \( A_0 \) of the graded ring (0.2) with \( A_0' = k \), or replace the component \( A_0 \) of the big graded ring (9.4) with \( A'_{L''(0)} = k \) for \( L' = L'' \) and 0 otherwise. The Koszul property of the (big) graded ring \( A \) is equivalent to the same property of the (big) graded ring \( A' = A_0' \oplus A_1 \oplus A_2 \oplus \cdots \), and the latter (big) graded ring is flat over its zero-degree component \( A_0' \), so the characterization of Koszulity from Sections 7.3–7.4 applies. When \( k \) is a field, this further simplifies to the classical Koszul property of \( k \)-algebras [34], [42], [36].
By Corollary 7.10, the Koszulity conditions for coefficients \( k = \mathbb{Z}/p^r \) or \( \mathbb{Z}/l^r \) in the cases (ii) and (iii) are equivalent to the Koszulity conditions for the coefficients \( \mathbb{Z}/p \) or \( \mathbb{Z}/l \), where \( p = \text{char} \, K \) or \( l \neq \text{char} \, K \) are prime numbers.

**9.6. Tate motives with finite coefficients.** Consider the case when \( k = \mathbb{Z}/l \) and the field \( K = M \) contains a primitive \( l \)-root of unity.

It was proven in [42] that Koszulity of the Milnor algebra \( K^{M}(K)/l \) for all finite extensions \( K \) of a given field \( F \) implies the Milnor–Bloch–Kato conjecture for the field \( F \), assuming that the latter conjecture holds in small degrees (the norm residue homomorphism in an isomorphism in the degree \( n = 2 \) and a monomorphism in the degree \( n = 3 \)). Furthermore, Koszulity of \( K^{M}(K)/l \) together with the Beilinson–Lichtenbaum conjecture implies Conjecture 9.2 for Tate motives with coefficients \( \mathbb{Z}/l \) over \( K \), as explained in Section 9.5.

Conversely, assuming the Milnor–Bloch–Kato conjecture and Conjecture 9.2 for Tate motives with coefficients \( \mathbb{Z}/l \) over \( K \), Koszulity of the algebra \( K^{M}(K)/l \) follows due to [40], [21] and the results from Section 9.5. So Koszulity of the Milnor algebra \( K^{M}(K)/l \) together with the low-degree part of the Milnor–Bloch–Kato conjecture are equivalent to the full Milnor–Bloch–Kato conjecture together with Conjecture 9.2 for Tate motives with finite coefficients \( \mathbb{Z}/l \).

When all these conjectures hold, the triangulated category \( \mathcal{D} \) of Tate motives with coefficients \( \mathbb{Z}/l \) over \( K \) is simply described as the derived category \( \mathcal{D}^{b}(\mathcal{F}) \) of the exact category \( \mathcal{F} \) of finitely filtered discrete \( G_{K} \)-modules \((N, F) \) over \( \mathbb{Z}/l \) such that \( G_{K} \) acts trivially on the quotient modules \( F^{i}N/F^{i+1}N \).

Thus the silly filtration conjecture provides a motivic interpretation [35] of the Koszulity conjecture from [42].

**9.7. Torsion Tate motives.** Let \( K \) be a field and \( m \geq 2 \) be an integer prime to \( \text{char} \, K \). Imagine that there is a \( \mathbb{Z}/m \)-linear triangulated category \( \mathcal{D}' \) generated by objects \( \mathbb{Z}/d(i) \) for all \( d \) dividing \( m \) and \( i \in \mathbb{Z} \). There is a shift functor \( X \mapsto X(1) \) on \( \mathcal{D}' \) transforming \( \mathbb{Z}/d(i) \) to \( \mathbb{Z}/d(i + 1) \), and the triangulated subcategory in \( \mathcal{D}' \) generated by \( \mathbb{Z}/d(0) \) is identified with the bounded derived category of \( \mathbb{Z}/m \)-modules.

The conventional triangulated category \( \mathcal{D} \) of Tate motives with coefficients \( \mathbb{Z}/m \) over \( K \) is embedded into \( \mathcal{D}' \) as the triangulated subcategory generated by \( \mathbb{Z}/m(i) \). One has \( \text{Hom}_{\mathcal{D}}(\mathbb{Z}/d(i), \mathbb{Z}/d'(j)[n]) = 0 \) for all \( n < 0 \) and \( i, j \in \mathbb{Z} \).

Finally, there is the étale realization functor \( \Phi \colon \mathcal{D}' \to \mathcal{D} \), where \( \mathcal{E} \) denotes the abelian category of discrete \( G_{K} \)-modules over \( \mathbb{Z}/m \). This functor agrees with the étale realization functor for \( \mathcal{D} \subset \mathcal{D}' \) (so the groups \( \text{Hom}_{\mathcal{D}}(\mathbb{Z}/m(i), \mathbb{Z}/m(j)) \) are described by the Beilinson–Lichtenbaum formulas) and its restriction to the subcategory generated by \( \mathbb{Z}/d(0) \) coincides with the obvious functor (of “trivial \( G_{K} \)-action”) from the bounded derived category of \( \mathbb{Z}/m \)-modules to \( \mathcal{D} \).

Then one can easily prove by induction on the cohomological degree \( n \) that the subcategories \( \mathcal{E}' \subset \mathcal{D}' \) consisting of finite direct sums of the objects \( \mathbb{Z}/d(i) \) satisfy the conditions (3.1–3.2). Thus the minimal full subcategory \( \mathcal{M}' \subset \mathcal{D}' \) containing all \( \mathbb{Z}/d(i) \) and closed under extensions is equivalent to the exact category \( \mathcal{F}' \) of finitely filtered discrete \( G_{K} \)-modules \((N, F) \) over \( \mathbb{Z}/m \) such that the quotient \( G_{K} \)-modules \( F^{i}N/F^{i+1}N \otimes_{\mathbb{Z}/m} \mu_{m}^{\otimes -1} \) are finitely generated over \( \mathbb{Z}/m \) with a trivial action of \( G_{K} \).
Let $\mathcal{M}$ denote the minimal full subcategory of $\mathcal{D}$ containing the objects $\mathbb{Z}/m(i)$ and closed under extensions. It would be interesting to know under what assumptions all the maps $\text{Ext}^{n}_{\mathcal{M}}(X, Y) \rightarrow \text{Ext}^{n}_{\mathcal{M}'}(X, Y)$ are isomorphisms, or equivalently, all the maps $\text{Ext}^{n}_{\mathcal{M}}(X, Y) \rightarrow \text{Hom}_{\mathcal{D}'}(X, Y[n])$ are isomorphisms.

**9.8. Cyclic extension of prime degree.** Let $k = \mathbb{Z}/l$ and $M/K$ be a cyclic extension of degree $l$ of fields containing a primitive $l$-root of unity. Assume that the Milnor–Bloch–Kato conjecture holds for fields $M$ and $K$ and coefficients $k$. In this case, the graded ring (0.2) has the form

$$A = \bigoplus_{n} \text{Ext}^{n}_{\mathcal{M}}(k \oplus k[G_{K}/G_{M}], k \oplus k[G_{K}/G_{M}])$$

$$\simeq H^{*}(G_{K}, \mathbb{Z}/l) \oplus H^{*}(G_{M}, \mathbb{Z}/l) \oplus H^{*}(G_{M}, \mathbb{Z}/l) \oplus H^{*}(G_{M}, \mathbb{Z}/l)[G_{K}/G_{M}],$$

where $\mathcal{E}$ is the abelian category of discrete $G_{K}$-modules over $\mathbb{Z}/l$.

There is a conjecture [37, Conjecture 16] that $H^{n+1}(G_{M}, \mathbb{Z}/l)$ is a Koszul module over a Koszul algebra $H^{*}(G_{K}, \mathbb{Z}/l)$. By [36, Corollary 6.2(b)], it follows from this conjecture that the graded algebra $A' = k \oplus A_{1} \oplus A_{2} \oplus \cdots$ is Koszul. Consequently, the graded ring $A$ is also Koszul. Thus, according to Section 9.5, Conjecture 9.2 follows from [37, Conjecture 16] for such a field extension $M/K$ and coefficients $k$.

**9.9. Artin–Tate motives and extensions of the basic field.** Let $k$ be a coefficient ring and $M/K'$ be a tower of fields such that $M/K$ is a Galois extension. Then the silly filtration conjecture for Artin–Tate motives holds for the field extension $M/K'$ provided that it holds for the extension $M/K$ with the same coefficients $k$.

Indeed, passage to the inductive limit with respect to the functors of extension of scalars reduces the question to the case when the field extension $K'/K$ is finite. In this case, the functor of extension of scalars $\mathcal{D}(K, k) \rightarrow \mathcal{D}(K', k)$ is right adjoint to the functor of restriction of scalars $\mathcal{D}(K', k) \rightarrow \mathcal{D}(K, k)$. Both functors send the Artin–Tate motives $k[L/K](i)$ or $k[L/K'](i)$ over $K$ or $K'$ corresponding to fields $L \subset M$ to (finite direct sums of) similar motives over $K'$ or $K$, respectively. Moreover, any motive $k[L/K'](i)$ over $K'$ is a direct summand of the image of the motive $k[L/K](i)$ under the extension of scalars functor. The assertion now follows from (the dual version of) Proposition B.1.

**9.10. New approach to Milnor–Bloch–Kato conjecture.** Let $l$ be a prime number and $K$ be a field of characteristic different from $l$ having no finite separable extensions of degree prime to $l$. Set $M = \overline{K}$ to be the separable closure of $K$ and let $A$ be the corresponding big graded ring of diagonal $\text{Hom}$ for Artin–Tate motives (9.4) with coefficients $\mathbb{Z}/l$. Consider also the related big graded ring $A'$ (see Section 9.5).

Assume that the Galois symbol (norm residue homomorphism) for finite extensions of the field $K$ and coefficients $\mathbb{Z}/l$ is an isomorphism in degree $n = 2$ and a monomorphism in degree $n = 3$. Then whenever the big graded ring $A$ (or, equivalently, $A'$) is Koszul, this map is an isomorphism in all degrees for such fields and such coefficients. This follows from Theorem 8.4. This is another version of the approach to the Milnor–Bloch–Kato conjecture suggested in [42]. Notice that
by Section 9.9 the Koszulity condition that appears here holds for all algebraic extensions of a field \( K \) if holds for \( K \).

**9.11. Koszulity of cohomology.** As a general heuristic rule, the cohomology algebra \( H^*(X) \) of an object \( X \) is Koszul (as a graded ring with the cohomological grading) if and only if two conditions hold:

1. \( X \) is of a \( K(\pi, 1) \) type; and
2. the DG-algebra computing \( H^*(X) \) is “quasi-formal”, meaning that the higher Massey products (defined as the differentials in the spectral sequence converging from the cohomology of the bar-construction of \( H^*(X) \) to the cohomology of the bar-construction of the DG-algebra computing it) in \( H^*(X) \) vanish.

In particular, any formal DG-algebra (i.e., DG-algebra which can be connected with its cohomology by a chain of multiplicative quasi-isomorphisms) is quasi-formal. Concerning the \( K(\pi, 1) \) condition, it has to be interpreted in a way consistent with the cohomology theory under consideration. A discussion of the situation when \( X \) is a rational homotopy type and \( H^*(X) = H^*(X, \mathbb{Q}) \) can be found in [33].

In particular, given a profinite group \( G \) and a prime number \( l \), the cohomology algebra \( H^*(G, \mathbb{Z}/l) \) is Koszul if and only if

1. the natural map \( H^*(G^{(l)}, \mathbb{Z}/l) \to H^*(G, \mathbb{Z}/l) \) induced by the map \( G \to G^{(l)} \) from the group \( G \) to its maximal quotient pro-\( l \)-group \( G^{(l)} \) is an isomorphism of graded algebras; and
2. the higher Massey products in \( H^*(G, \mathbb{Z}/l) \) vanish.

Assuming that \( H^*(G, \mathbb{Z}/l) \) is Koszul, a proof of (1) can be found in [36, Section 5] and (2) tautologically holds for the grading reasons. To deduce Koszulity from (1) and (2), notice that the coalgebra \( \mathbb{Z}/l(G^{(l)}) \) of locally constant \( \mathbb{Z}/l \)-valued functions on \( G^{(l)} \) is conilpotent, hence the bar-construction of its cobar-construction, being quasi-isomorphic to it [39, Theorem 6.10(b)], has cohomology concentrated in degree 0.

A very general version of the implication Koszulity \( \Rightarrow K(\pi, 1) \) is provided by Corollary 8.5.

Since it suffices to prove the Milnor–Bloch–Kato conjecture for the fields whose Galois groups are pro-\( l \)-groups, it follows that this conjecture, taken together with the silly filtration conjecture for Tate motives with coefficients \( \mathbb{Z}/l \) over fields containing a primitive \( l \)-root of unity, are equivalent to the assertion that the higher Massey products in \( H^*(G_K, \mathbb{Z}/l) \) vanish for any such field \( K \).

Notice that the DG-algebra computing the Galois cohomology with coefficients in \( \mathbb{Z}/l \) is not in general formal, only conjecturally quasi-formal. Indeed, the Koszulity means that the associated graded coalgebra of \( \mathbb{Z}/l(G_K^{(l)}) \) with respect to the coaugmentation filtration is Koszul and quadratic dual to \( H^*(G_K, \mathbb{Z}/l) \) [42]. The formality would mean that \( \mathbb{Z}/l(G_K^{(l)}) \) is isomorphic to this associated graded coalgebra, i.e., admits a Koszul grading.

Let \( K \) be a finite extension of \( \mathbb{F}_p((z)) \) or \( \mathbb{Q}_p \), with \( p \neq l \); assume that \( K \) contains a primitive \( l \)-root of unity if \( l \) is odd, or a square root of \(-1\) if \( l = 2 \). Then the algebra \( H^*(G_K, \mathbb{Z}/l) \) is an exterior algebra with two generators [40], so its quadratic dual
coalgebra is a symmetric coalgebra with two generators. If the group coalgebra \( \mathbb{Z}/l(G^{(i)}) \) of \( G_K^{(i)} \) were quasi-isomorphic to the latter coalgebra, it would mean that \( G_K^{(i)} \) is commutative. This is not the case; in fact, \( G_K^{(i)} \) is a semidirect product of two copies of \( \mathbb{Z}_l \) with one of them acting nontrivially in the other one.

9.12. Tate motivic sheaves over a scheme. The following attempt to describe the triangulated category of Tate motives/motivic sheaves with finite coefficients \( \mathbb{Z}/m \) over a smooth variety \( S \) over a field \( K \) of characteristic not dividing \( m \) looks natural. Its development was influenced by the author’s conversations with V. Vologodsky.

Consider the exact category \( \mathcal{F} \) whose objects are finitely filtered étale sheaves of \( \mathbb{Z}/m \)-modules \( (\mathcal{N}, F') \) over \( S \) such that the quotient sheaf \( F^i\mathcal{N}/F^{i+1}\mathcal{N} \) is the tensor product of a sheaf of \( \mathbb{Z}/m \)-modules lifted from the Zariski/Nisnevich topology of \( S \) with the étale sheaf \( \mu_{m^i}^{\otimes i} \). Let \( \mathcal{D} \) be the full triangulated subcategory of \( \mathcal{D}^b(\mathcal{F}) \) generated by the Tate objects \( \mathbb{Z}/m(i) \), which are identified with the sheaves \( \mu_{m^i}^{\otimes i} \) placed in the filtration component \( i \).

Then \( \mathcal{D} \) is the candidate triangulated category of Tate motivic sheaves over \( S \). The main piece of evidence supporting this conjecture that is presently known to the author is that both the motivic cohomology of \( S \) and \( \mathbb{Z}/m \)-modules \( \text{Ext} \) between the Tate objects in the triangulated category \( \mathcal{D} \) localize in the Zariski topology. So it suffices to consider the case when \( S \) is the spectrum of the local ring of a scheme point on a smooth variety.

A different version of this construction (for Artin–Tate rather than Tate motivic sheaves) is shown to work, under certain assumptions, in the forthcoming paper [41].

9.13. Tate motives and discrete valuation rings. The following purports to answer a question posed to the author by V. Vologodsky. Let \( V \) be a discrete valuation ring with quotient field \( K \) and residue field \( k \). Let \( m = l^r \) be a power of a prime different from \( \text{char } k \). Consider the embeddings of schemes \( \nu: \text{Spec } K \rightarrow \text{Spec } V \) and \( \iota: \text{Spec } k \rightarrow \text{Spec } V \). The functor \( \iota^* \nu_*: \mathcal{D} \text{Mot}(K, \mathbb{Z}/m) \rightarrow \mathcal{D} \text{Mot}(k, \mathbb{Z}/m) \) is supposed to take the triangulated subcategory of Tate motives in \( \mathcal{D} \text{Mot}(K, \mathbb{Z}/m) \) into the triangulated subcategory of Tate motives in \( \mathcal{D} \text{Mot}(k, \mathbb{Z}/m) \). Below we suggest a conjectural description of this functor on Tate motives in terms of complexes of filtered modules over the absolute Galois groups \( G_K \) and \( G_k \).

There is a natural closed subgroup \( G_L \subset G_K \) corresponding to the Henselization \( L \) of the discrete valuation field \( K \). The group \( G_L \) is the quotient of \( G_K \) by the inertia subgroup \( I \). Since \( l \neq \text{char } k \), the maximal quotient pro-\( l \)-group \( I_l = I/I' \) of the group \( I \) is naturally isomorphic to the projective limit \( \mathbb{Z}_l(1) \) of the groups \( \mu_{l^i} \) of \( l^i \)-roots of unity in \( \overline{k} \) (or equivalently, in \( \overline{L} \)), while the (profinite) order of the group \( I' \) is not divisible by \( l \).

Let \( (N, F) \) be a finitely filtered discrete \( G_K \)-module over \( \mathbb{Z}/m \) whose quotient modules \( g_{i_F}^j N \) are finite direct sums of the modules \( \mu_{m^i}^{\otimes i} \). Restrict the action of \( G_K \) in \( N \) to \( G_L \); since the subgroup \( I \subset G_L \) acts in \( N \) by endomorphisms unipotent with respect to the filtration \( F \), its action factorizes through \( I_l \). Hence the quotient group \( G_L/I_l' \) acts in \( N \).
Let $x$ be a topological generator of the group $I_l = \mathbb{Z}_l(1)$ and $\bar{x}$ be the corresponding generator of the group $\mu_m$. Consider the map $R_x: (x - 1) \otimes \bar{x}^{-1}: N \to N \otimes_{\mathbb{Z}_l/m} \mu_m^{\otimes -1}$. Since $x$ acts trivially in $\mathfrak{gr}_F N$, this map shifts the filtration, i.e., defines a morphism of filtered $\mathbb{Z}/m$-modules $N \to N(-1)$. Unless $k$ contains all the $l'$-roots of unity, this map does not respect the action of $G_L/I'$, however.

To deal with this problem, consider the expression $\phi(x, n) = 1 + x + \cdots + x^{n-1}$, defined for all nonnegative integers $n$ and taking values in the endomorphisms of $N$. The equations $\phi(x, a + b) = \phi(x, a) + x^a \phi(x, b)$ and $\phi(x, ab) = \phi(x, a)\phi(x^a, b)$ hold. One easily checks that the function $\phi$ can be extended by continuity to a locally constant function of $n \in \mathbb{Z}_l$. For any $n \in \mathbb{Z}_l$, set $\phi_x(x^n) = \phi(x, n)$; then $\phi_x$ is a 1-cocycle of the group $I_l$ with coefficients in the filtration-preserving endomorphisms of $N$, i.e., the equation $\phi_x(yz) = \phi_x(y) + y\phi_x(z)$ holds for $y, z \in I_l$.

For any $n \in \mathbb{Z}_l^*$, set $\psi_x(n) = \phi(x, n); n$; then the function $\psi_x$ takes values in the automorphisms of $N$ unipotent with respect to $F$ and satisfies the cocycle equation $\psi_x(ab) = \psi_x(a)\psi_x(b)$.

Let $\rho: G_L/I' \to \text{Aut}_{\mathbb{Z}_l/m}(N(-1))$ be the action of $G_L/I'$ in $N(-1)$ induced by the actions of $G_L/I'$ in $N$ and $\mu_m$. Define a new action $\rho_x: G_L/I' \to \text{Aut}_{\mathbb{Z}_l/m}(N(-1))$ by the rule $\rho_x(g) = \psi_x(\chi(g))^{-1}\rho(g)$, where $\chi: G_L/I' \to \mathbb{Z}_l^*$ is the cyclotomic character. This new action is associative due to the above cocycle equation for $\psi$, since $gxg^{-1} = x\chi(g)$. Denote the filtered $\mathbb{Z}/m$-module $N(-1)$ endowed with this new action of the group $G_L/I'$ by $N(-1_x)$. Then $N(-1)_x$ is a finitely filtered $G_L/I'$-module with cyclotomic associated quotients, and one readily checks that $R_x: N \to N(-1)_x$ is a morphism of filtered $G_L/I'$-modules.

Replacing $x$ with $x^n$, where $n \in \mathbb{Z}_l^*$, we obtain a similar morphism $R_{x^n}: N \to N(-1)_x$. The isomorphism of filtered $G_L/I'$-modules $\psi_x(n): N(-1)_x \to N(-1)_y^n$ identifies the morphisms $R_x$ and $R_{y^n}$, which makes the two-term complex of filtered $G_L/I'$-modules $R_x: N \to N(-1)_x$, denoted symbolically by $R: N \to N(-1)$, defined uniquely up to a unique isomorphism.

Now we can assign to any bounded complex $(N^\bullet, F)$ of finitely filtered discrete $G_K$-modules over $\mathbb{Z}/m$ with cyclotomic associated quotients the total complex of the bicomplex with two rows $R: N^\bullet \to N^\bullet(-1)$. The complex so obtained is a bounded complex of finitely filtered $G_L/I'$-modules with cyclotomic associated quotients. We need to transform it into a similar complex of $\bar{G}_k$-modules.

Pick a uniformizing element $\pi$ in the ring $\mathfrak{V}$ (or even in the field $L$). Then one can extend the field $L$ by adjoining a compatible system of $l'$-roots of $\pi$. This (not necessarily normal, but separable) algebraic field extension corresponds to a section $G_k \to G_L/I'$ of the surjective profinite group homomorphism $G_L/I' \to G_k$. Composing the action of $G_L/I'$ with this section, we obtain the desired complex of filtered $G_k$-modules.

A change of the compatible system of $l'$-roots of $\pi$ corresponds to an element of the kernel $\mathbb{Z}_l(1) = I_l$ of the group homomorphism $G_L/I' \to G_k$, and the conjugation with this element transforms one of the related two sections $G_k \to G_L/I'$ into the other. The action of this element defines the complex of $G_k$-modules that we have constructed as independent of the choice of the compatible system of roots of $\pi$ up to a unique isomorphism.
Finally, assume that \( \pi' \) and \( \pi'' \) are two uniformizing elements, and compatible systems of \( l' \)-roots have been chosen for each of them. Then we have two sections \( \sigma', \sigma'' : G_k \to G_k/l' \) differing by a cocycle \( \xi : G_k \to I_l \); so \( \sigma'(g) = \sigma''(g)\xi(g) \).

Consider the two two-term complex of \( G_k \)-modules \( R_{x'} : N_{\sigma'} \to N(-1)_{x,\sigma'} \) and \( R_{x''} : N_{\sigma''} \to N(-1)_{x,\sigma''} \) obtained by composing the action of \( G_k \) in the two-term complex \( R_{x} : N \to N(-1)_{x} \) with \( \sigma' \) and \( \sigma'' \). We will construct a two-term complex of finitely filtered \( G_k \)-modules with cyclotomic associated quotients \( \widetilde{R} : \tilde{N} \to \tilde{M} \) together with two quasi-isomorphisms \( p' \) and \( p'' \) mapping this intermediate complex onto each of the two complexes that we need to compare.

The filtered \( G_k \)-module \( \tilde{N} \) is simply the direct sum \( N_{\sigma'} \oplus N_{\sigma''} \); its morphisms \( p' \) and \( p'' \) to \( N_{\sigma'} \) and \( N_{\sigma''} \) are the projections to the direct summands. The filtered \( G_k \)-module \( \tilde{M} \) is an extension of \( N(-1)_{x,\sigma'} \) with the kernel \( N_{\sigma''} \). We construct it as the filtered \( \mathbb{Z}/m \)-module \( N \oplus N(-1) \) endowed with the action of \( G_k \) given by the formula \( g(u, v) = (\sigma'(g)(u) + \sigma''(g)\xi(g))(v \otimes x) \). This action is associative due to the cocycle equations for \( \phi \).

The morphisms \( p' : \tilde{M} \to N(-1)_{x,\sigma'} \) and \( p'' : \tilde{M} \to N(-1)_{x,\sigma''} \) are given by the rules \( p'(u, v) = v \) and \( p''(u, v) = v + R_{x}(u) \). One checks that the kernels of \( p' \) and \( p'' \) are contractible two-term complexes.

Notice that the above construction is not applicable to Artin–Tate motives, since the action of \( \mathbb{Z}/l(1) \) on the associated quotient modules of the related filtered modules can be nontrivial, so the compatibility with the filtration breaks down.

9.14. Milnor ring with integral coefficients. Due to the results of this paper (see Section 7), we now know what it means for the Milnor ring (with integral coefficients) \( K^M(K) \) of a field \( K \) to be Koszul.

It is still a mystery whether one should expect it to be Koszul for an arbitrary field \( K \), or what the motivic interpretation of it being Koszul might consist in. In fact, we do not know this even for the algebra \( K^M(K) \otimes_{\mathbb{Z}} \mathbb{Q} \) (see Section 10).

9.15. Tate motivic DG-algebra \( A \). Fix a field \( K \). We are interested in a negatively internally graded DG-algebra \( A \) over \( \mathbb{Z} \) (see Appendix C) such that for any coefficient ring \( k \) as above the full triangulated subcategory of the derived category of internally graded DG-modules over \( A \otimes_{\mathbb{Z}} k \) generated by the free DG-modules \( A \otimes_{\mathbb{Z}} k(i) \) is equivalent to the full triangulated subcategory of \( DM(K, k) \) generated by the Tate objects \( k(i) \). Moreover, the free DG-modules \( A \otimes_{\mathbb{Z}} k(i) \) should correspond to the Tate objects \( k(i) \) under this equivalence of triangulated categories, and the underlying bigraded \( \mathbb{Z} \)-module of the DG-algebra \( A \) should be flat (i.e., torsion-free). In particular, the cohomology \( H(A \otimes_{\mathbb{Z}} k) \) of the DG-algebra \( A \otimes_{\mathbb{Z}} k \) should be isomorphic to the motivic cohomology of \( K \) with coefficients in \( k \).

There must be many candidate constructions of the DG-algebra \( A \) obtainable from the contemporary literature; we will suggest just one such construction adopted to Voevodsky’s definition [49] of the triangulated category of geometric motives. It was inspired by the papers [8], [12]. Consider the additive category \( SimCor \) of smooth schemes over \( k \) and finite correspondences between them, and pass to the DG-category of bounded complexes over \( SimCor \). The latter is a tensor DG-category with respect to the Cartesian product of schemes over \( k \); in particular, there
is the DG-endofunctor of Tate twist acting on it. Consider the full DG-subcategory of the “relations” of homotopy invariance and Mayer–Vietoris; close it under the Tate twists and apply the construction of Drinfeld localization [17, Section 3]. Set

$$A_i = \lim_{i \to j} \text{Hom}(\mathbb{Z}(i + j), \mathbb{Z}(j))$$

for $i < 0$, the Hom being taken in the DG-category we have constructed; $A_0 = k$, and $A_i = 0$ for $i > 0$. It is clear that this construction is compatible with tensoring with a ring of coefficients $k$ in a reasonable sense.

Another approach is to use one of the various constructions of the complex of algebraic cycles (see, e.g., [12]) in the role of $A$.

9.16. Classical $K(\pi, 1)$-conjecture and integral Tate motives. Now let $C$ denote the reduced bar-construction of the DG-algebra $A$ over $\mathbb{Z}$. By Theorem C.1, the main conjecture from Section 9.2 for $M = K$ and $k = \mathbb{Z}$ is equivalent to the DG-coalgebra $C$ having no cohomology in the positive cohomological degrees, $H^n(C) = 0$ for $n > 0$.

By Proposition C.2(1), the Beilinson–Soulé vanishing conjecture with rational coefficients is equivalent to $C \otimes_{\mathbb{Z}} \mathbb{Q}$ having no cohomology in the negative cohomological degrees, $H^n(C \otimes_{\mathbb{Z}} \mathbb{Q}) = 0$ for $n < 0$. For the same reason, one expects $H^n(C \otimes_{\mathbb{Z}} \mathbb{Z}/p) = 0$ for $n < 0$ if $K$ has a prime characteristic $p$ (see Section 9.5). Finally, by Theorem C.3(1), the Beilinson–Lichtenbaum conjecture implies $H^n(C \otimes_{\mathbb{Z}} \mathbb{Z}/l) = 0$ for $n < -1$ and any prime number $l \neq \text{char } K$.

By the universal coefficients formula, it follows that one should expect $H^n(C) = 0$ for all $n \neq 0$. However, $H^0(C)$ is not supposed to be a torsion-free $\mathbb{Z}$-module; indeed, it should have nontrivial $l$-torsion for any $l \neq \text{char } K$. Conversely, if $H^n(C) = 0$ for $n \neq 0$, then $H^n(A/\mathbb{Z}) = 0$ for $n \leq 0$, $H^n(A \otimes_{\mathbb{Z}} k) = 0$ for $n < 0$ and any coefficient ring $k$, and the silly filtration conjecture holds for $M = K$ and any $k$.

As to the cohomology coalgebra $H(C \otimes_{\mathbb{Z}} \mathbb{Z}/l)$, one can expect it to be described by the assertions of Theorem C.3(2–3).

9.17. Tate motivic DG-coalgebra $C$ and its cohomology coalgebra. In general, given a flat DG-coalgebra $C$ over $\mathbb{Z}$ with nonflat cohomology $H(C)$, there is no way to define a coalgebra structure on $H(C)$, as the natural map $H(C) \otimes_{\mathbb{Z}} H(C) \to H(C \otimes_{\mathbb{Z}} C)$ has no natural inverse. However, when $H^n(C) = 0$ for $n \neq 0$, there is a natural coassociative coalgebra structure on $H^0(C)$. Moreover, assume that $C$ is negatively internally graded, and consider the minimal full subcategory $\mathcal{M}$ of the derived category of internally graded DG-comodules over $C$, containing the trivial DG-comodules $\mathbb{Z}(i)$ and closed under extensions. Since the homological dimension of $\mathbb{Z}$ is equal to 1, $\mathcal{M}$ is an exact subcategory of the triangulated category $\mathcal{D}$ it generates. Now there is an exact cohomology functor from $\mathcal{M}$ to the exact category $\mathcal{G}$ of comodules over $H^0(C)$, free and finitely generated as $\mathbb{Z}$-modules.

But this functor is not an equivalence. It suffices to consider the example when $K = \mathbb{F}_p$ is the algebraic closure of a finite field. In this case, the internally graded DG-coalgebra $C$ should be quasi-isomorphic to the DG-coalgebra with the only nonzero components $C_0 = \mathbb{Z}$ and $C_{-1} = (\mathbb{Z}[q^{-1}] \to \mathbb{Q})$, the term $\mathbb{Z}[q^{-1}]$ being
placed in the cohomological degree \(-1\) and the term \(\mathbb{Q}\) in the cohomological degree 0, with the identity embedding of \(\mathbb{Z}[q^{-1}]\) into \(\mathbb{Q}\) as the differential. Using the reduced cobar-construction, one can compute that \(\text{Hom}_{\mathcal{M}}(\mathbb{Z}(i), \mathbb{Z}(j)) = \mathbb{Z}\) and \(\text{Ext}^1_{\mathcal{M}}(\mathbb{Z}(i), \mathbb{Z}(j)) = \mathbb{Q}/\mathbb{Z}[q^{-1}]\) for \(i < j\), while all the other Ext groups between the objects \(\mathbb{Z}(i)\) in the exact category \(\mathcal{M}\) vanish (cf. Section 9.18). In the exact category \(\mathcal{G}\), the groups \(\text{Ext}^1_{\mathcal{G}}(\mathbb{Z}(i), \mathbb{Z}(j)) = 0\) for \(i + 2 \leq j\) differ from those in \(\mathcal{M}\) (while all the other Ext groups between the objects \(\mathbb{Z}(i)\) are the same).

Nor such a description of the exact category \(\mathcal{M}\) in terms of the nonflat coalgebra \(H^0(C)\), if it existed, would be of much use; see Remark 7.1. Instead, it appears that one has to learn how to work with the DG-coalgebra \(C\) up to a quasi-isomorphism in the class of negatively internally graded DG-coalgebras with torsion-free underlying bigraded \(\mathbb{Z}\)-modules. It is impossible in general to recover such a quasi-isomorphism class of a DG-coalgebra \(C\) with \(H^n(C) = 0\) for \(n \neq 0\) from the graded coalgebra structure on \(H^0(C)\), as one can see in the case when \(C_{-1}\) and \(C_{-2}\) are nonzero, while \(C_{-i} = 0\) for \(i \geq 3\). The point is, the map of complexes of \(\mathbb{Z}\)-modules \(C_{-1} \to C_{-1} \otimes_{\mathbb{Z}} C_{-1}\) is not determined, as a morphism in the derived category of \(\mathbb{Z}\)-modules, by the induced map of the cohomology.

9.18. Integral Tate motives over finite field. One example when the derived category of Tate motives with integral coefficients admits an elementary construction is that of motives over a finite field. One expects that

\[
\begin{align*}
\text{Hom}_{\mathcal{D}M}(\mathbb{F}_q, \mathbb{Z})(\mathbb{Z}(0), \mathbb{Z}(i)[1]) &\simeq \mu_{q^i-1}^\otimes, & \text{for } i \geq 0; \\
\text{Hom}_{\mathcal{D}M}(\mathbb{F}_q, \mathbb{Z})(\mathbb{Z}(0), \mathbb{Z}(i)[n]) &\simeq 0, & \text{for } i \neq 0, n \neq 1.
\end{align*}
\] (9.5)

Since \(\text{Hom}_{\mathcal{D}M}(\mathbb{Z}(i), \mathbb{Z}(j)[n]) = 0\) for \(n \geq 2\), the silly filtration condition is trivial in this case. One can construct an exact category \(\mathcal{F}\) with the Ext groups given by (9.5), except that \(\mu_{q^i-1}\) is replaced with \(\mathbb{Z}/(q^i - 1)\), in the following way.

First let us describe an exact category \(\mathcal{F}\) resembling mixed Tate motives over the algebraic closure of a finite field \(\mathbb{F}_q\) with integral coefficients. Consider the category of finitely filtered abelian groups \((N, F)\) endowed with a (fixed) splitting of the filtration over \(\mathbb{Z}_{(p)}\), i.e., \(N \otimes_{\mathbb{Z}} \mathbb{Z}_{(p)} \simeq \text{gr}_F N \otimes_{\mathbb{Z}} \mathbb{Z}_{(p)}\). Here \(\mathbb{Z}_{(p)}\) denotes the localization of \(\mathbb{Z}\) at the prime ideal \((p)\). It is also required that \(\text{gr}_F N\) be a finitely generated free abelian group. Define the objects \(\mathbb{Z}(i) \in \mathcal{F}\) as the groups \(\mathbb{Z}\) placed in the filtration component \(i\). Then one has \(\text{Hom}_\mathcal{F}(\mathbb{Z}(i), \mathbb{Z}(j)) = \mathbb{Z}\) and \(\text{Ext}_\mathcal{F}^1(\mathbb{Z}(i), \mathbb{Z}(j)) \simeq \mathbb{Q}/\mathbb{Z}[q^{-1}]\) for \(i < j\), while all the remaining Ext groups between the objects \(\mathbb{Z}(i)\) vanish. All objects of \(\mathcal{F}\) are iterated extensions of \(\mathbb{Z}(i)\).

Now consider the case of mixed Tate motives over \(\mathbb{F}_q\) with coefficients in \(\mathbb{Z}[q^{-1}]\). Consider the exact category \(\mathcal{F}\) of finitely filtered \(\mathbb{Z}[q^{-1}]-\)modules \((N, F)\) endowed with an endomorphism \(\phi: N \to N\) that is compatible with the filtration \(\mathcal{F}\) and acts by multiplication with \(q^i\) on the successive quotient \(F^i N / F^{i+1} N\). It is required that \(\text{gr}_F N\) be a finitely generated free module over \(\mathbb{Z}[q^{-1}]\). Define the objects \(\mathbb{Z}[q^{-1}](i) \in \mathcal{F}\) as the modules \(\mathbb{Z}[q^{-1}]\) placed in the filtration component \(i\), with \(\phi\) acting on them by \(q^i\). Then one has \(\text{Hom}_\mathcal{F}(\mathbb{Z}[q^{-1}](i), \mathbb{Z}[q^{-1}](i)) = \mathbb{Z}[q^{-1}]\) and \(\text{Ext}_\mathcal{F}^1(\mathbb{Z}[q^{-1}](i), \mathbb{Z}[q^{-1}](j)) \simeq \mathbb{Z}/(q^{i-j} - 1)\) for \(i \leq j\), while all the remaining Ext groups between the objects \(\mathbb{Z}[q^{-1}](i)\) vanish.
Finally, to construct an exact category $F$ resembling mixed Tate motives over $\mathbb{F}_q$ with integral coefficients, consider finitely filtered abelian groups $(N, F)$ endowed with a family of endomorphisms $\phi^{(i)}: F^i N \to F^i N$ such that $\phi^{(i)}|_{F^j N} = q^{i-j} \phi^{(j)}$ for $i \leq j$ and the action of $\phi^{(i)}$ on $F^i N/F^{i+1} N$ is the identity endomorphism. Define the objects $Z(i) \in F$ as the groups $Z$ placed in the filtration component $i$, with $\phi^{(j)}$ acting on them by $q^{i-j}$. Then one has $\text{Hom}_F(Z(i), Z(i)) = \mathbb{Z}$ and $\text{Ext}^1_F(Z(i), Z(j)) \simeq \mathbb{Z}/(q^{j-i} - 1)$ for $i \leq j$, while all the remaining Ext groups between the objects $Z(i)$ vanish.

9.19. Epilogue. One of the most important problems of the theory around the Milnor–Bloch–Kato conjecture is to describe as precisely as possible the special properties of absolute Galois groups, their cyclotomic characters, their subgroups, their cohomology, etc. One particular aspects of this problem is to describe the behavior of Galois cohomology with constant/cyclotomic coefficients with respect to extensions of the field $K$.

This project was originally conceived as an approach to the latter problem. The hope was that the main conjecture from Section 9.2 would impose strong restrictions on the behavior of Galois cohomology in field extensions. This hope did not quite materialize, as it now appears that the main conjecture is not so strong.

Consider the case of a cyclic extension of prime degree $M/K$ and arbitrary coefficients $k$. Then the graded algebra $A$ from (0.2) is isomorphic to

$$k \otimes_{\mathbb{Z}} (K^M(K) \oplus K^M(M) \oplus K^M(M) \oplus K^M(M)[G_K/G_M]).$$

The multiplication in this algebra is defined in terms of the map $K^M(K) \to K^M(M)$ induced by the embedding of fields $K \to M$, the transfer map $K^M(M) \to K^M(K)$, and the action of $G_K/G_M$ on $K^M(M)$.

We have mentioned already in Section 9.4 that the algebra $A$ is generated by $A_1$ over $A_0$. Furthermore, either a weak form of Hilbert theorem 90 for the Milnor $K$-theory or the statement of the Bass–Tate lemma are both sufficient to conclude that $A$ is quadratic. And in the situation of Section 9.8, Koszulity of $A$ follows from the conjecture from [37], but there is no apparent way to obtain the converse implication.

Thus the main our achievements in this paper are the connection of the silly filtration conjecture with Koszulity conjectures established in Section 9.5 and the elementary construction of the category of mixed Artin–Tate motives with finite coefficients obtained in Section 9.3. In addition, there is the result of Section 9.16 on the $K(\pi, 1)$-conjecture with integral coefficients.

**Appendix A. Exact Categories**

**A.1. Preadditive categories.** A preadditive category $A$ is a category in which the set of morphisms $\text{Hom}_A(X, Y)$ between any two given objects is endowed with the structure of an abelian group in such a way that the composition maps are biadditive. A functor $F: A \to B$ between preadditive categories is called additive if it takes the sums of morphisms in $A$ to the sums of morphisms in $B$.

In particular, a preadditive category with a single object is the same that a (noncommutative) ring. For this reason, we will use the term big ring over a set $\Sigma$
as another name for a small preadditive category with the set of objects \( \Sigma = \text{Ob} \mathcal{A} \).

In other words, a big ring over \( \Sigma \) is a collection of abelian groups \((A_{\sigma \tau})_{\sigma, \tau \in \Sigma}\), satisfying the conventional biadditivity, associativity, and unit axioms. One can think of \( A \) with multiplication maps \( A_{\sigma \tau} \times A_{\tau \rho} \rightarrow A_{\sigma \rho} \) and unit elements \( e_\sigma \in A_{\sigma \sigma} \) satisfying the conventional axioms.

Let \( \mathcal{A}b \) denote the category of abelian groups. A left module over a big ring \( A \) over \( \Sigma \) is another name for a covariant additive functor \( A \rightarrow \mathcal{A}b \), and a right module over \( A \) is a contravariant additive functor between the same categories. In other words, a left-\( A \)-module \( M \) is a collection of abelian groups \((M_\tau)_{\tau \in \Sigma}\) together with action maps \( A_{\sigma \tau} \times M_\tau \rightarrow M_\sigma \), and similarly for right modules. Given a big ring \( A \) over \( \Sigma \) and a big ring \( B \) over \( \Pi \), a bimodule \( K \) over \( A \) and \( B \) is a collection of abelian groups \((K_{\tau \rho})_{\tau \in \Sigma, \rho \in \Pi}\) together with biaction maps \( A_{\sigma \tau} \times K_{\tau \rho} \times B_{\rho \pi} \rightarrow K_{\sigma \pi} \) satisfying the obvious triadditivity, associativity, and unit axioms.

It follows from the latter definition that a bimodule over big graded rings can not be literally viewed as a left or a right module over one of the big rings; rather, it is the standard properties of the functor Tor over a ring; in particular, resolving either \( A \)-side, and homology \( A \)-side, will speak of bimodules as if they have underlying left and right module structures, omitting the references to collections of modules for brevity. Any operations with collections of modules are performed with every module in the collection, providing the corresponding collections of outputs; any properties of collections of modules are meant to hold for any module in the collection.

Let \( M \) be a left \( A \)-module and \( N \) be a right \( A \)-module; then the tensor product \( N \otimes_A M \) is the abelian group generated by the formal symbols \( n \otimes m \), where \( n \in N_\sigma \) and \( m \in M_\tau \), subject to the conventional relations \( na \otimes m = n \otimes am \) for any \( n \in N_\sigma \), \( a \in A_{\sigma \tau} \), and \( m \in M_\tau \), and biadditivity. As explained above, this simultaneously defines the operation of tensor product of bimodules; in particular, the tensor product of two \( A \)-bimodules is again an \( A \)-bimodule.

The category of \( A \)-(bi)modules is an abelian category satisfying Ab5 and Ab4*, with a set of generators, and enough projectives and injectives \([22]\). For any set \( I \) mapping into \( \Sigma \) one defines the free left \( A \)-module \( M \) generated by \( I \) by the rule \( M_\tau = \bigoplus_{i \in I} A_{\tau, \sigma(i)} \), and similarly for free right modules. These are just direct sums of representable functors on \( \mathcal{A} \). An \( A \)-module is projective if and only if it is a direct summand of a free module.

The functor of tensor product over \( A \) is right exact. A right \( A \)-module \( N \) is flat if the functor \( M \mapsto N \otimes_A M \) is exact on the abelian category of left \( A \)-modules. Any projective \( A \)-module is flat. One defines the left derived functors \( \text{Tor}_n^A(N, M) \) for \( n \geq 0 \), a right \( A \)-module \( N \) and a left \( A \)-module \( M \), by the conventional derived functor procedure, using projective or flat resolutions. The derived functors have the standard properties of the functor Tor over a ring; in particular, resolving either argument leads to the same result.

A big ring \( A \) over a set \( \Sigma \) is said to be graded if every abelian group \( A_{\sigma \tau} \) is graded. In this paper, we only consider big rings graded by nonnegative integers. Thus a big graded ring is a collection of abelian groups \((A_{\sigma \tau, n})_{\sigma, \tau \in \Sigma, n \geq 0}\) endowed with multiplication maps \( A_{\sigma \tau, n} \times A_{\tau \rho, m} \rightarrow A_{\sigma \rho, n+m} \) and unit elements \( e_\sigma \in A_{\sigma \sigma, 0} \) satisfying the conventional biadditivity, associativity, and unit axioms. One can consider graded modules over big graded rings in the obvious sense.

For a further discussion of rings with several objects, see \([30]\).
A.2. Additive categories. One can show that if an object $X$ of a preadditive category $A$ is the product of a finite set of objects $X_i \in A$, then it is also the coproduct of this set of objects, and vice versa. In this case, $X$ is called the direct sum of $X_i$. An additive category is a preadditive category in which the (co)product of any finite set of objects exists. The preadditive category structure on an additive category can be recovered from its abstract category structure.

Following the terminology of A. Neeman's paper [31], we call an additive category $A$ semi-saturated (weakly idempotent complete) if any pair of its morphisms $p: X \to Y$ and $i: Y \to X$ such that $p \circ i = id_Y$ comes from an isomorphism $X \cong Y \oplus Z$ for some object $Z \in A$. An additive category is called saturated (Karoubian, pseudo-abelian, idempotent complete) if any its morphism $e: X \to X$ such that $e \circ e = e$ is the projection on a direct summand of a decomposition $X \cong Y \oplus Z$.

For any additive category $A$ there exists a unique, up to a uniquely defined equivalence, semi-saturated additive category $A_{ss}$ (called the semi-saturation of $A$) together with an additive functor $ss: A \to A_{ss}$ such that any additive functor from $A$ to a semi-saturated additive category $B$ can be factorized through the functor $ss$ in a unique, up to an isomorphism, way. There also exists a unique, up to a uniquely defined equivalence, saturated additive category $A_{sat}$ (called the saturation of $A$) together with an additive functor $sat: A \to A_{sat}$ satisfying the same condition with respect to functors from $A$ to saturated additive categories $B$.

Let $A$ be a full additive subcategory of an additive category $B$. Then the semi-saturation closure $A_{ss}^B$ of the subcategory $A$ in $B$ is the full subcategory of $B$ whose objects are all the objects $Z \in B$ for which there exists an object $Y \in A$ such that the object $X \oplus Y$ is also isomorphic to an object from $A$. The saturation closure $A_{sat}^B$ of a subcategory $A$ is defined in the same way except that one allows $Y \in B$.

For example, any additive category admitting either the kernels or the cokernels of all morphisms (see below) is saturated. Any triangulated category is semi-saturated. A triangulated subcategory of a triangulated category is thick if and only if it coincides with its saturation closure [31]. The saturation of a triangulated category is naturally a triangulated category again [1].

Example A.1. To see just how bad a nonsaturated additive category can be, consider the category $A$ of all vector spaces $V$ over a field $k$ such that $\dim V \neq 1, 2, \text{ or } 5$. This is an additive subcategory of the category of vector spaces, since it is closed under direct sums. The category $A$ is not even semi-saturated. On the other hand, the category $B$ of all finite-dimensional vector spaces of dimension divisible by 3 over $k$ is an example of a semi-saturated, but not saturated additive category. The category of finitely generated free modules over a ring $R$ is not even semi-saturated in general.

A morphism $k: K \to X$ in a preadditive category $A$ is called the kernel of a morphism $f: X \to Y$ if for any object $Z \in A$ the sequence

$$0 \to \text{Hom}_A(Z, K) \to \text{Hom}_A(Z, X) \to \text{Hom}_A(Z, Y)$$

is exact; in this case we write $K = \text{Ker } f$ and $k = \text{ker } f$. Analogously, a morphism $c: Y \to C$ is called the cokernel of a morphism $f: X \to Y$ if for any object $Z \in A$
there is an exact sequence
\[ 0 \rightarrow \text{Hom}_A(C, Z) \rightarrow \text{Hom}_A(Y, Z) \rightarrow \text{Hom}_A(X, Z); \]
the notation: \( C = \text{Coker} f \) and \( c = \text{coker} f \). A morphism \( f \) is called injective if one has \( \text{Ker} f = 0 \) and surjective if \( \text{Coker} f = 0 \).

Throughout this appendix, we will sometimes use the following notation for computations in additive categories: the composition of several (previously defined) morphisms, say \( X \rightarrow Y, Y \rightarrow Z, \) and \( Z \rightarrow T \), will be denoted by \( [X \rightarrow Y \rightarrow Z \rightarrow T] \). Then an equation like \( [X \rightarrow Y \rightarrow Z] = [X \rightarrow T \rightarrow Z] \) means that the morphisms form a commutative square, etc.

**A.3. Axioms.** There is a very detailed recent exposition [15] of the theory of exact categories, covering most of the material that one needs to know in order to feel at ease while working with these things. The purpose of the following subsections is to complement that exposition with several observations which will tend to add some clarity as far as our goals are concerned, or present an independent interest.

Let \( \mathcal{E} \) be an additive category endowed with a class of admissible (or exact) triples of objects and morphisms
\[ \mathcal{T}_E = \{ X' \rightarrow X \rightarrow X'' \}, \quad X', X, X'' \in \mathcal{E}. \]
A morphism \( X \rightarrow Y \) in the category \( \mathcal{E} \) will be called an admissible monomorphism if it can be embedded into an admissible triple \( X' \rightarrow X \rightarrow X'' \) and an admissible epimorphism if there exists an admissible triple \( T \rightarrow X \rightarrow Y \). An additive category \( \mathcal{E} \) together with a class of admissible triples \( \mathcal{T}_E \) is called an exact category if it satisfies the following axioms Ex0–Ex3:

**Ex0:** The zero triple \( 0 \rightarrow 0 \rightarrow 0 \) is admissible. Any triple isomorphic to an admissible triple is admissible.

**Ex1:** For any admissible triple \( X' \rightarrow X \rightarrow X'' \) and any object \( Z \in \mathcal{E} \) there are exact sequences
\[ 0 \rightarrow \text{Hom}_{\mathcal{E}}(Z, X') \rightarrow \text{Hom}_{\mathcal{E}}(Z, X) \rightarrow \text{Hom}_{\mathcal{E}}(Z, X''), \]
\[ 0 \rightarrow \text{Hom}_{\mathcal{E}}(X'', Z) \rightarrow \text{Hom}_{\mathcal{E}}(X, Z) \rightarrow \text{Hom}_{\mathcal{E}}(X', Z). \]
In other words, the morphisms \( X' \rightarrow X \) and \( X \rightarrow X'' \) are each other’s kernel and cokernel.

**Ex2:** Let \( X' \rightarrow X \rightarrow X'' \) be an admissible triple. Then (a) for any morphism \( X' \rightarrow Y' \) there exists a commutative diagram
\[ X' \rightarrow X \rightarrow X'' \]
\[ \downarrow \quad \downarrow \]
\[ Y' \rightarrow Y \] (A.1)
with an admissible triple \( Y' \rightarrow Y \rightarrow X'' \); and analogously, (b) for any morphism \( Y'' \rightarrow X'' \) there exists a commutative diagram

\[
\begin{array}{ccc}
X' & \rightarrow & X \\
\downarrow & & \downarrow \\
Y & \rightarrow & Y''
\end{array}
\]

with an admissible triple \( X' \rightarrow Y \rightarrow Y'' \).

**Ex3:** (a) The composition of any two admissible monomorphisms is an admissible monomorphism. (b) The composition of any two admissible epimorphisms is an admissible epimorphism.

This list of axioms roughly corresponds to the axioms for exact categories commonly used in modern expositions [24], [15], with two exceptions. Firstly, the numbering is different, and secondly, our axiom Ex2 is usually stated in a different form; see axiom Ex2’ below. We prefer our axiom Ex2.

We will show that for any class of admissible triples \( \mathcal{T}_E \) satisfying Ex0–Ex2 the diagrams (A.1) and (A.2) in Ex2 are defined uniquely up to a unique isomorphism by the original triple \( X' \rightarrow X \rightarrow X'' \) and the morphism \( X' \rightarrow Y' \) or \( Y'' \rightarrow X'' \), respectively. The object \( Y \) in the diagram (A.1) is necessarily the fibered coproduct of the morphisms \( X' \rightarrow Y' \) and \( X' \rightarrow X \) and the object \( Y \) in the diagram (A.2) is the fibered product of the morphisms \( Y'' \rightarrow X'' \) and \( X \rightarrow X'' \). In other words, the axiom Ex2 is equivalent modulo Ex0–Ex1 to the following axiom Ex2’.

**Ex2’:** (a) For any admissible monomorphism \( X' \rightarrow X \) and any morphism \( X' \rightarrow Y' \) there exists a fibered coproduct \( Y = Y' \sqcup_X X \) in the category \( \mathcal{E} \) and the natural morphism \( Y' \rightarrow Y \) is an admissible monomorphism.

(b) For any admissible epimorphism \( X \rightarrow X'' \) and any morphism \( Y'' \rightarrow X'' \) there exists a fibered product \( Y = Y'' \sqcap_X X \) in the category \( \mathcal{E} \) and the natural morphism \( Y'' \rightarrow Y'' \) is an admissible epimorphism.

Furthermore, the axiom Ex2 together with the condition that the additive category \( \mathcal{E} \) be semi-saturated is equivalent modulo Ex0–Ex1 to the following axiom Ex2”.

**Ex2”:** (a) A right divisor \( g \) of an admissible monomorphism \( fg \) is an admissible monomorphism.

(b) A left divisor \( f \) of an admissible epimorphism \( fg \) is an admissible epimorphism.

(c) If in the following commutative diagram

\[
\begin{array}{ccc}
X' & \rightarrow & X_1 \\
\downarrow & & \downarrow \\
X_2 & \rightarrow & X''
\end{array}
\]

both triples \( X' \rightarrow X_1 \rightarrow X'' \) and \( X' \rightarrow X_2 \rightarrow X'' \) are admissible, then the morphism \( X_1 \rightarrow X_2 \) is an isomorphism.
The conditions Ex2’(a–b) are a stronger version of the last “obscure” axiom in Quillen’s list of axioms for exact categories [43]. The obscure axiom claims that a right divisor of an admissible monomorphism is an admissible monomorphism provided that it has a cokernel, and a left divisor of an admissible epimorphism is an admissible epimorphism provided that it has a kernel. It is known [24], [15] that the obscure axiom follows from the other ones. The above stronger form of the obscure axiom holds if and only if $E$ is semi-saturated [25], [15]. The condition Ex2”(c) follows from Ex0–Ex1 and any of the conditions Ex2(a) or Ex2(b).

Finally, it is known that the conditions Ex3(a) and Ex3(b) are equivalent modulo Ex0–Ex2 (see [24]). Sketches of proofs of the above equivalence assertions are given in the next subsection.

**A.4. Proofs.** In what follows we assume that an additive category $E$ is endowed with a class of admissible triples satisfying the axioms Ex0–Ex1.

**Proposition A.2.** It follows from the condition Ex2(a) that if in the diagram (A.1) the triple $Y' \rightarrow Y \rightarrow X''$ is admissible and the morphism $X \rightarrow X''$ is the cokernel of the morphism $X' \rightarrow X$, then the object $Y$ is the fibered coproduct $Y = Y' \sqcup_X X$ in the category $E$. Analogously, it follows from Ex2(b) that if in the diagram (A.2) the triple $X' \rightarrow Y \rightarrow X''$ is admissible and the morphism $X' \rightarrow X$ is the kernel of the morphism $X \rightarrow X''$, then the object $Y$ is the fibered product $Y = Y'' \cap_{X''} X$.

**Proof.** We have to show that for any object $Z \in E$ there is a bijective correspondence between the set of all morphisms $Y \rightarrow Z$ and the set of all pairs of morphisms $Y' \rightarrow Z$ and $X \rightarrow Z$ which form a commutative diagram with $X' \rightarrow Y'$ and $X' \rightarrow X$. Suppose a morphism $Y \rightarrow Z$ is annihilated by the compositions with $Y' \rightarrow Y$ and $X \rightarrow Y$. By Ex1, $f$ factorizes through the morphism $Y \rightarrow X''$. Since the morphism $X \rightarrow X''$ is assumed to be a cokernel, it follows that $f = 0$.

Now let us assume that we are given a compatible pair of morphisms $Y' \rightarrow Z$ and $X \rightarrow Z$. Applying Ex2 to the admissible triple $Y' \rightarrow Y \rightarrow X''$ and the morphism $Y' \rightarrow Z$, we obtain an admissible triple $Z \rightarrow T \rightarrow X''$ together with the commutative diagram

$$
\begin{array}{ccc}
X' & \rightarrow & X \\
\downarrow & & \downarrow \\
Y' & \rightarrow & Y \\
\downarrow & & \downarrow \\
Z & \rightarrow & T
\end{array}
$$

Consider the morphism $\chi: X \rightarrow T$ that is equal to the difference of two compositions $\chi = [X \rightarrow Y \rightarrow T] - [X \rightarrow Z \rightarrow T]$. We have $[X' \rightarrow X \rightarrow Z] = 0$, since $[X' \rightarrow X \rightarrow Y \rightarrow T] = [X' \rightarrow Y' \rightarrow Z \rightarrow T]$ and $[X' \rightarrow Y' \rightarrow Z] = [X' \rightarrow X \rightarrow Z]$. Therefore, the morphism $\chi$ factorizes into the composition $\chi = [X \rightarrow X'' \rightarrow T]$ for some morphism $X'' \rightarrow T$. The composition $X'' \rightarrow Z \rightarrow T$ is the identity, since $[X \rightarrow X'' \rightarrow Z \rightarrow T \rightarrow X'''] = [X' \rightarrow X \rightarrow Z \rightarrow T \rightarrow X'''] = [X \rightarrow X'' \rightarrow Z \rightarrow T \rightarrow X'''] = [X \rightarrow X'' \rightarrow T \rightarrow X''']$, and the morphism $X \rightarrow X''$ is surjective. It follows that...
the morphism \( \text{id}_T - [T \to X'' \xrightarrow{\phi} T] \) annihilates \( T \to X'' \) and, therefore, factorizes into the composition \( [T \xrightarrow{\phi} Z \to T] \) for some morphism \( T \xrightarrow{\phi} Z \).

Let us check that the morphism \( f = [Y \xrightarrow{\phi} Z \to T] \) is the desired one. We have \( [Y \xrightarrow{\phi} Z \to T] = [Y \to T \xrightarrow{\phi} Z \to T] = [Y \to T] - [Y \to T \to X'' \xrightarrow{\phi} T] = [Y \to T] - [Y \to X'' \xrightarrow{\phi} T] \). Now \( [X \to Y \xrightarrow{\phi} Z \to T] = [X \to Y \to T] - [X \to Y \to X'' \xrightarrow{\phi} T] = [X \to Y \to T] - [X \to X'' \xrightarrow{\phi} T] = [X \to Y \to T] - [X \xrightarrow{\phi} T] = [X \xrightarrow{\phi} Z \to T] \), which implies \( [X \to Y \xrightarrow{\phi} Z] = [X \xrightarrow{\phi} Z] \). Similarly, \( [Y' \to Y \xrightarrow{\phi} Z \to T] = [Y' \to Y \to T] - [Y' \to Y \to X'' \xrightarrow{\phi} T] = [Y' \to Y \to T] - [Y' \to T] = [Y' \xrightarrow{\phi} Z \to T] \), hence \( [Y' \to Y \xrightarrow{\phi} Z] = [Y' \xrightarrow{\phi} Z] \).

\[ \Box \]

**Corollary A.3.** The conditions Ex2(a) and Ex2'(a) are equivalent modulo Ex0–Ex1. Analogously, the conditions Ex2(b) and Ex2'(b) are equivalent modulo Ex0–Ex1. \[ \Box \]

**Proposition A.4.** If the axioms Ex0–Ex1 are satisfied, then the axiom Ex2'' holds if and only if the additive category \( \mathcal{E} \) is semi-saturated and the axiom Ex2 holds.

**Proof.** It follows from Proposition A.2 that any of the conditions Ex2(a) or Ex2(b) implies Ex2''(c). We already know that Ex2 is equivalent to Ex2', and it is proven in [24], [25] that Ex2' implies Ex2''(a–b) if \( \mathcal{E} \) is semi-saturated. Conversely, it is easy to see [25] that \( \mathcal{E} \) is semi-saturated whenever any of the conditions Ex2''(a) or Ex2'(b) holds. We will deduce Ex2 from Ex2'' below.

Let \( X' \to X \to X'' \) be an admissible triple and \( X' \to Y' \) be a morphism. By the condition Ex2''(a), the morphism \( X' \xrightarrow{(1,1)} Y' \oplus X \) is an admissible monomorphism. Let \( Y' \oplus X \xrightarrow{(1,1)} Y \) be its cokernel. Clearly, there exists a unique morphism \( Y \to X'' \) such that the diagram (A.1) is commutative and the composition \( Y'' \to Y \to X'' \) is zero. By the condition Ex2''(b), the morphism \( Y \to X'' \) is an admissible epimorphism. It remains to show that the morphism \( Y' \to Y \) is its kernel. It is clear that the morphism \( Y \to X'' \) is the cokernel of the morphism \( Y' \to Y \).

Let \( K \to Y \) be the kernel of the morphism \( Y \to X'' \); then there is a natural morphism \( Y' \to K \). First let us show that the latter morphism is surjective. Suppose that the composition \( Y' \to K \to Z \) vanishes for a certain morphism \( K \to Z \). Repeating the above construction starting with the admissible triple \( K \to Y \to X'' \) and the morphism \( K \to Z \), we obtain a commutative diagram

\[
\begin{array}{ccc}
Y' & \longrightarrow & K \\
\downarrow & & \downarrow \\
Z & \longrightarrow & T
\end{array}
\]

where the triple \( K \xrightarrow{(1,1)} Z \oplus Y \xrightarrow{(1,1)} T \) is admissible. Since the morphism \( K \to Y \) is injective, the morphism \( Z \to T \) is injective, too. Since the composition \( [Y' \to K \to Y \to T] = [Y' \to K \to Z \to T] \) vanishes and the morphism \( Y \to X'' \) is the cokernel of the morphism \( Y' \to Y \), the morphism \( Y \to T \) factors into the composition \( Y \to X'' \to T \) for some morphism \( X'' \to T \). Hence \( [K \to Z \to T] = [K \to Y \to X'' \to T] = 0 \), and it follows that \( [K \to Z] = 0 \).
Now consider the commutative diagram

\[
\begin{array}{ccc}
X' & \rightarrow & Y' \oplus X \\
\downarrow & & \downarrow \\
K \oplus X & \rightarrow & Y
\end{array}
\]

The upper triple is admissible, and the morphism \(X' \rightarrow K \oplus X\) is an admissible monomorphism by Ex2''(a). Using the fact that the vertical morphism is surjective, one can check that the morphism \(K \oplus X \rightarrow Y\) is the cokernel of the morphism \(X' \rightarrow K \oplus X\). It remains to apply the condition Ex2''(c). □

**Example A.5.** The following counterexample shows that the condition Ex2''(c) is indeed necessary. Let \(A\) be the additive category whose objects are morphisms of vector spaces \(f: V'' \rightarrow V'\) endowed with a subspace \(V \subset \text{Im } f\) and let \(T_A\) be the class of all triples for which Ex1 holds. One can check that this class of admissible triples satisfies Ex0–Ex1, Ex2''(a–b), and Ex3, but not Ex2''(c).

Note that if two classes of triples \(T'_E\) and \(T''_E\) satisfy the axioms Ex0–Ex2, then their union \(T'_E \cup T''_E\) also does. In particular, one has to use the axiom Ex3 in order to prove that the direct sum of two admissible triples is an admissible triple. The next counterexample shows that even if one assumes the latter property, the conditions Ex0–Ex2 still wouldn’t imply Ex3.

**Example A.6.** Let \(B\) be the abelian category of 3-term sequences of vector spaces \(V^{(1)} \rightarrow V^{(2)} \rightarrow V^{(3)}\) (the composition can be nonzero). There are six indecomposable objects in this category; we will denote them by \(E_1, E_2, E_3, E_{12}, E_{23}, E_{123}\), where \(\dim E^{(i)}_J = 1\) for \(i \in J\) and 0 otherwise. Let \(T_B\) be the class of all exact triples \(X' \rightarrow X \rightarrow X''\) in the abelian category \(B\) such that for any morphism \(X' \rightarrow E_3\) the triple \(E_{23} \rightarrow Y \rightarrow X''\) induced from the original triple using the composition of morphisms \(X' \rightarrow E_3 \rightarrow E_{23}\) is split. Then it is not difficult to check that the class \(T_B\) satisfies Ex0–Ex2 and is closed under direct sums, but the composition of two admissible monomorphisms \(E_3 \rightarrow E_{23}\) and \(E_{23} \rightarrow E_{123}\) is not an admissible monomorphism with respect to \(T_B\).

An additive functor between exact categories is said to be exact if it sends admissible triples to admissible triples.

**A.5. Examples.** Some examples of exact categories are listed below.

1. The trivial exact category structure: for any additive category \(A\), the class of all split triples \(X' \rightarrow X' \oplus X'' \rightarrow X''\) satisfies the axioms of an exact category.

2. The canonical exact category structure on an abelian category: the class of all short exact sequences in any abelian category satisfies the axioms Ex0–Ex3.

3. Let \((A, T_A)\) be an exact category and \(\mathcal{E} \subset A\) be a full additive subcategory. Then \(\mathcal{E}\) is called a full exact subcategory of \(A\) if the class \(T_{\mathcal{E}}\) of all triples in the category \(\mathcal{E}\) which belong to \(T_A\) is an exact category structure on \(\mathcal{E}\). Any of the following two conditions is sufficient for \(\mathcal{E}\) to be a full exact subcategory in \(A\):
   (a) the subcategory \(\mathcal{E}\) contains the middle term \(X\) of any admissible triple \(X' \rightarrow \)
Whenever it contains the middle term and one of the other terms.

Consider the category \( E \) whose objects are pairs of objects \( A \in A \) and \( B \in B \) together with an isomorphism \( \alpha \). Set a triple in \( E \) to be admissible if its images in \( A \) and \( B \) are admissible. Then \( E \) is an exact category.

A filtered object \( X \) in an exact category \( E \) is a collection of objects \( \text{gr}^{a,b} X \in E \) for all \( a \leq b \in \mathbb{Z} \) and morphisms \( \text{gr}^{c,d} X \to \text{gr}^{a,b} X \) for all \( a \leq c \) and \( b \leq d \) compatible with the compositions and such that all the triples \( \text{gr}^{a+c,b} X \to \text{gr}^{a,b} X \to \text{gr}^{a,b} X \) are admissible. A triple of filtered objects \( X' \rightarrow X \rightarrow X'' \) is admissible if all the triples \( \text{gr}^{a,b} X' \rightarrow \text{gr}^{a,b} X \to \text{gr}^{a,b} X'' \) are admissible in the category \( E \), or equivalently, all the triples \( \text{gr}^{a} X' \to \text{gr}^{a} X \to \text{gr}^{a} X'' \) are admissible, where one denotes \( \text{gr}^{a} X = \text{gr}^{a,a} X \). A finitely filtered object is a filtered object \( X \) such that one has \( \text{gr}^{a} X = 0 \) for all but a finite number of indices \( a \). The category of (finitely) filtered objects in an exact category is an exact category.

Let \( E \) be an exact category. Define a triple in \( E^{\text{ss}} \) or \( E^{\text{sat}} \) to be admissible if it is a direct summand of an admissible triple in \( E \). Then \( E^{\text{ss}} \) and \( E^{\text{sat}} \) become exact categories, and \( E \) is closed under extensions (cf. (3a)) in each of them. Conversely, if \( A \) is an exact category and \( E \subset A \) is a full exact subcategory such that every object of \( A \) is a direct summand of an object of \( E \), then \( E \) is closed under extensions in \( A \) if and only if every triple from \( T_A \) is a direct summand of a triple from \( T_E \).

(7) Let \( E \) be an additive category in which all morphisms admit kernels and cokernels. For any morphism \( f : X \to Y \) in \( A \) consider the natural morphism \( \text{Coim} f = \text{Coker} (\ker f) \to \text{Im} f = \text{Ker} (\text{coker} f) \). Then the morphism \( \text{Coim} f \to \text{Im} f \) is surjective for any morphism \( f \) in \( A \) if and only if the composition of any two kernels is a kernel (of some morphism) in \( A \), if and only if a right divisor of any kernel is a kernel, and if and only if any two morphisms \( X' \to X \) and \( X' \to Y' \), the former of which is a kernel, can be embedded into a commutative square \( [X' \to X \to Y] = [X' \to Y' \to Y] \), where the morphism \( Y' \to Y \) is injective. The dual assertions relate injectivity of the morphisms \( \text{Coim} f \to \text{Im} f \) with the properties of cokernels.

The class of all triples satisfying axiom Ex1 defines an exact category structure on \( A \) if and only if it satisfies axiom Ex2′(c) and all the above properties of kernels and cokernels hold in \( A \). In this case, the additive category \( A \) is said to be quasi-abelian. (Cf. [45] .)

Example A.5 shows that the requirement of axiom Ex2′(c) cannot be dropped. For an example of an additive category where kernels do not have the above properties, consider the abelian category \( B \) from Example A.6 and its full subcategory \( A \) whose objects are the direct sums of all the indecomposables except \( E_{12} \). Then the morphism \( f : E_0 \to E_{123} \) is a composition of two kernels but not a kernel, and the morphism \( \text{Coim} f \to \text{Im} f \) is not surjective (moreover, it is a kernel).

One can show that any semi-saturated additive category \( A \) admits a maximal exact category structure, that is a class of triples satisfying Ex0–Ex3 and containing any other such class of triples.
More precisely, it is clear that in any additive category $\mathcal{A}$ there exists a maximal class of triples satisfying Ex0–Ex2. In fact, this class consists of all triples $X' \to X \to X''$ satisfying Ex1 such that for any morphisms $X' \to Y'$ and $Z'' \to X''$ the fibered coproduct $Y = Y' \sqcup_X X$ exists and the morphism $Y' \to Y$ is a kernel, the fibered product $Z = Z'' \cap_X X$ exists and the morphism $Z \to Z''$ is a cokernel; and the fibered product $Z'' \cap_Y Y$ exists. In this case, the fibered coproduct $Y' \sqcup_X Y$ also exists and is isomorphic to $Z'' \cap_X Y$ (equivalently, one could require existence of the former and deduce existence of the latter together with their isomorphism).

We claim that when $\mathcal{A}$ is semi-saturated, this class of triples $X' \to X \to X''$ also satisfies Ex3.

All the above assertions are quite straightforward to prove, except the ones from Examples (7–8). The proofs of the latter are given below.

Proof of (7). Let us prove the assertions from the first paragraph; the assertion from the second paragraph will then follow from Proposition A.4.

Since the morphism $X \to \Coim f$ is a cokernel, the morphism $\Coim f \to \Im f$ is surjective if and only if the morphism $X \to \Im f$ is surjective. Let us show that this is the case if the composition of two kernels is a kernel. Let $c: Y \to C$ be the cokernel of the morphism $f$; by the definition, the morphism $\im f: \Im f \to Y$ is the kernel of $c$. Let $d: \Im f \to D$ be the cokernel of the morphism $X \to \Im f$ and $l: L \to \Im f$ be the kernel of the morphism $d$. By the assumption, the composition $(\im f) \circ l: L \to Y$ should be a kernel. Since the morphism $X \to \Im f$ factors through $l$ and the composition $L \to Y \to C$ is zero, it is easy to deduce that $c$ is the cokernel of the morphism $L \to Y$. Now it turns out that both the morphisms $\Im f \to Y$ and $L \to Y$ are the kernels of the morphism $Y \to C$, hence the morphism $L \to \Im f$ is an isomorphism and $d = 0$.

Conversely, let us show that the composition $f$ of two kernels $K \to L$ and $L \to M$ is a kernel whenever the morphism $\Coim f \to \Im f$ is surjective. The morphism $f$ is equal to the composition $K \to \Im f \to M$; by the assumption, the morphism $K \to \Im f$ is surjective. Since the morphism $\Im f \to M$ is a kernel, it suffices to check that the morphism $K \to \Im f$ is an isomorphism. The latter is a particular case of the following general statement, which is not difficult to prove: a surjective right divisor of a composition of several kernels is an isomorphism.

Now let us show that a right divisor of a kernel is a kernel provided that the composition of two kernels is a kernel. Let $f: K \to Y$ and $Y \to Z$ be a pair of morphisms whose composition $K \to Z$ is the kernel of a morphism $Z \to D$. Let $c: Y \to C$ be the cokernel of the morphism $K \to Y$ and $\im f: \Im f \to Y$ be kernel of $c$; then the morphism $K \to Y$ factors through $\im f$. Since we have $[K \to Y \to Z \to D] = 0$, it is clear that the composition $Y \to Z \to D$ factors through $c$ and, consequently, $[\im f \to Y \to Z \to D] = 0$. Since the morphism $K \to Z$ is the kernel of the morphism $Z \to D$, there exists a morphism $\im f \to K$ such that $[\im f \to Y \to Z] = [\im f \to K \to Y \to Z]$. We have constructed morphisms between $K$ and $\im f$ in both directions; since the morphism $K \to Z$ is injective and $[K \to \im f \to K \to Y \to Z] = [K \to \im f \to Y \to Z] = [K \to Y \to Z]$, it follows that $[K \to \im f \to K] = \id K$. Therefore, the morphism $K \to \im f$ is the embedding.
of a direct summand, hence it is a kernel and the morphism \( f: K \to Y \) is the composition of two kernels \( K \to \text{Im} f \) and \( \text{Im} f \to Y \).

Furthermore, assume that a right divisor of a kernel is a kernel. Let a morphism \( K \to L \) be the kernel of a morphism \( c: L \to C \) and a morphism \( l: L \to M \) be the kernel of a morphism \( d: M \to D \). Consider the anti-diagonal morphism \((c, -l): L \to C \oplus M\); since its composition with the projection \( C \oplus M \to M \) is a kernel, the morphism \((c, -l)\) should be the kernel of a certain morphism \((i, e): C \oplus M \to E\). Since the morphism \( l: L \to M \) is injective, it is easy to see that the morphism \( i: C \to E \) is injective, too. Now one can check that the composition \( K \to L \to M \) is the kernel of the diagonal morphism \((d, e): M \to D \oplus E\). We have also shown that any pair of morphisms \( L \to M \) and \( L \to C \), where \( L \to M \) is a kernel, can be embedded into a commutative square \([L \to M \to E] = [L 
 L \to C \to E]\) with an injective morphism \( C \to E \).

Finally, assume that the latter condition holds. Let \( U \to T \) and \( T \to V \) be a pair of morphisms whose composition \( U \to V \) is the kernel of a morphism \( V \to W \). Consider the pair of morphisms \( U \to V \) and \( U \to T \), and suppose that there is a commutative square \([U \to V \to Q] = [U \to T \to Q]\) such that the morphism \( T \to Q \) is injective. Then one can check that the morphism \( U \to T \) is the kernel of the morphism \( T \to Q \oplus W \) with the components \([T \to Q] - [T \to V \to Q]\) and \([T \to V \to W]\).  

Proof of (8). To prove the assertion from the second paragraph, notice first of all that the triples \( Y' \to Y \to X'' \) and \( X' \to Z \to Z'' \) satisfy Ex1. For \( T = Z'' \cap X'' \), the functoriality of fibered (co)products provides two morphisms of triples with one common object \( X' \to Z \to Z'' \to Y' \to T \to Z'' \to Y \to X'' \). By the definition of \( T \) and since \( Y' = \text{Ker}(Y \to X'') \), it follows that \( Y' = \text{Ker}(T \to Z'') \). It remains to show that \( T = Y' \cap X' \), then it will follow that the triple \( Y' \to T \to Z'' \) satisfies Ex1, and the class of all triples of this form, where the original triple \( X' \to X \to X'' \) is fixed and the morphisms \( X' \to Y' \) and \( Z'' \to X'' \) vary, satisfies Ex2.

For any morphism \( Y' \to Y_2' \), applying our construction to the composition \( Y \to Y' \to Y'_2 \) in place of the morphism \( Y \to Y' \), we obtain an object \( T_2 = Z'' \cap X'' \) (\( Y'_2 \cap X' \)) together with a morphism of triples with one common object \( (Y' \to T \to Z'') \to (Y'_2 \to T_2 \to Z'') \). Since \( Y'_2 = \text{Ker}(T_2 \to Z'') \) and \( Z'' = \text{Coker}(X' \to Z) \), the argument from the proof of Proposition A.2 shows that \( T = Y' \cap X' \), \( Z \).

Let us turn to the assertion from the third paragraph. Whenever one is dealing with the axiom Ex3 in the assumption of Ex0–Ex2, the following commutative diagram (A.3) plays the key role.

\[
\begin{array}{ccc}
W & \rightarrow & Q \\
\downarrow P & & \downarrow Q \\
U & \rightarrow & V \\
\end{array}
\]

(A.3)
Given admissible monomorphisms $U \to P$ and $P \to H$, one considers admissible triples $U \to P \to W$ and $P \to H \to V$. Then one applies the property Ex2(a) or Ex2'(a) to the latter admissible triple and the morphism $P \to W$, obtaining an admissible triple $W \to Q \to V$. Hence the above commutative diagram. It is easy to check that the triple $U \to H \to Q$ satisfies Ex1. The morphism $U \to H$ is the composition of two admissible monomorphisms, and the morphism $H \to Q$ is a direct summand of the composition of two admissible epimorphisms $P \oplus H \to W \oplus H \to Q$ (see [24]).

In the situation of Example (8), one can readily check that the triple $U \to H \to Q$ allows the application of the push-forward procedure of axiom Ex2'(a) and then the pull-back procedure of axiom Ex2'(b), and continues to satisfy Ex1 after that. □

A.6. Embedding theorem. A small additive category $E$ endowed with a class of admissible triples $T_E$ is an exact category if and only if there exists an abelian category $A$ and a fully faithful functor $\rho: E \to A$ such that the subcategory $\rho(E) \subset A$ is closed under extensions and a triple $X' \to X \to X''$ in the category $E$ belongs to $T_E$ if and only if its image $\rho(X') \to \rho(X) \to \rho(X'')$ is a short exact sequence in $A$. In other words, the exact category structure on $E$ is induced from the canonical exact category structure on the abelian category $A$ in the sense of the above example (3a) from Section A.5. This is the statement of an embedding theorem first formulated by Quillen in [43] and proven in detail in several papers, including [47], [24], and [15].

In fact, any small exact category has two natural embeddings into abelian categories satisfying all the properties mentioned above; the two embeddings differ by the categorical duality. They are constructed in the following way. Consider the abelian category $Fun_{ad}(E^{op}, Ab)$ of contravariant additive functors from $E$ to the category of abelian groups $Ab$. A functor $F: E^{op} \to Ab$ is called left exact if for any admissible triple $X' \to X \to X''$ in the category $E$ the sequence of abelian groups

$$0 \to F(X'') \to F(X) \to F(X')$$

is exact. Let us denote by $A'(E) \subset Fun_{ad}(E^{op}, Ab)$ the full additive subcategory of left exact functors and by $\rho_{E}': E \to A'(E)$ the additive functor sending an object $X \in E$ to the representable contravariant functor $Home(-, X)$.

The category $A'(E)$ is abelian. This result is an additive version of the sheafification theory: arbitrary additive functors play the role of presheaves and the left exact functors are the sheaves. Note that the category $A'(E)$ is not an abelian subcategory of the category $Fun_{ad}(E^{op}, Ab)$: the embedding functor $A'(E) \to Fun_{ad}(E^{op}, Ab)$ is only left exact. The functor $Fun_{ad}(E^{op}, Ab) \to A'(E)$ left adjoint to the embedding is exact; however, this is the additive sheafification functor. Its construction is the main part of the proof. One can also view the category $A'(E)$ as the quotient category of $Fun_{ad}(E^{op}, Ab)$ by the kernel of the sheafification.

The second embedding $\rho_{E}'' : E \to A''(E)$ is defined in terms of the covariant representable functors; the category $A''(E)$ is the full subcategory of $Fun_{ad}(E, Ab)^{op}$ whose objects are all the left exact covariant functors. For example, if $E$ is the category of finitely generated free (or projective) left modules over a ring $R$ endowed with the trivial exact category structure, then the functor $\rho_{E}$ is the obvious
embedding into the abelian category of all left \( R \)-modules and the functor \( \rho'_E \) is the embedding into the abelian category opposite to the category of all right \( R \)-modules given by the rule \( \rho''(M) = \text{Hom}_R(M, R)^{\text{op}} \). The following result demonstrates the difference between the two canonical embeddings \( \rho'_E \) and \( \rho''_E \).

**Proposition A.7.** The functor \( \rho'_E \) preserves kernels, and more generally, any limits. In particular, for any morphism \( f \) in an exact category \( \mathcal{E} \), the morphism \( \rho'_E(f) \) is injective if and only if a morphism \( f \) is injective. For any morphism \( f \) in an exact category \( \mathcal{E} \), the morphism \( \rho'_E(f) \) is surjective if and only if \( f \) is a left divisor of some admissible epimorphism \( fg \) in \( \mathcal{E} \). In particular, if the category \( \mathcal{E} \) is semi-saturated, then the morphism \( \rho'_E(f) \) is surjective if and only if a morphism \( f \) is an admissible epimorphism. The dual statements hold for the embedding \( \rho''_E \).

**Proof.** The first assertion holds since all limits exist in a Grothendieck category \( \mathcal{A}'(\mathcal{E}) \) and the embedding \( \mathcal{A}'(\mathcal{E}) \to \text{Fun}_{\text{ad}}(\mathcal{E}^{\text{op}}, \text{Ab}) \) preserves limits. The third one follows from exactness of the functor \( \rho'_E \) with respect to admissible triples in \( \mathcal{E} \) and the next Proposition A.8, and the fourth one from axiom Ex2"(b).

**Proposition A.8.** For any objects \( A \in \mathcal{A}'(\mathcal{E}) \) and \( X \in \mathcal{E} \) and any surjective morphism \( A \to \rho'_E(X) \) in \( \mathcal{A}'(\mathcal{E}) \) there exists an admissible epimorphism \( Y \to X \) in \( \mathcal{E} \) and a morphism \( \rho'_E(Y) \to A \) in \( \mathcal{A}'(\mathcal{E}) \) such that the triangle \( \rho'_E(Y) \to A \to \rho'_E(X) \) is commutative in \( \mathcal{A}'(\mathcal{E}) \).

**Proof.** See [47, Lemma A.7.15] or [15, Lemma A.22].

### A.7. Derived categories.

Whenever one is working with exact categories, one is faced with an unpleasant choice between making the (semi-)saturated assumptions or doing without them. The former approach restricts generality, while the second one complicates matters; both the restrictions and the complications are felt as irrelevant and unnecessary. One ends up oscillating between the two ways by passing from a category to its (semi-)saturation and back, thus experiencing the worst aspects of both approaches. No good solution to this problem is known to the author.

In the definition of the derived category of an exact category, the (semi-)saturation problem presents itself in a particularly complicated form. We attempt to clarify the issues involved in the exposition below.

Given an additive category \( \mathcal{A} \), we denote by \( \mathcal{K}(\mathcal{A}) \) the homotopy category of (unbounded) complexes over \( \mathcal{A} \). The homotopy category of complexes bounded from above, below, and both sides are denoted by \( \mathcal{K}^{-}(\mathcal{A}), \mathcal{K}^{+}(\mathcal{A}), \) and \( \mathcal{K}(\mathcal{A}) \subset \mathcal{K}(\mathcal{A}) \). For \( * = \emptyset, -, +, \) or \( b \), we say that a complex \( X^\bullet \) over \( \mathcal{A} \) is \( * \)-bounded if \( X \) is respectively any complex, or a complex bounded from above, etc.

Let \( \mathcal{E} \) be an exact category. A complex \( X^\bullet \) over \( \mathcal{E} \) is said to be exact if there exist objects \( Z^i \in \mathcal{E} \) and admissible triples \( Z^i \to X^i \to Z^{i+1} \) such that the differentials \( X^i \to X^{i+1} \) in \( X^\bullet \) are equal to the compositions \( X^i \to Z^{i+1} \to X^{i+1} \). It is known [31], [15] that the cone of a closed morphism of exact complexes is exact. A complex \( X^\bullet \) is called acyclic if it is homotopy equivalent to an exact complex. The full subcategory of \( * \)-bounded acyclic complexes is denoted by \( \mathcal{A}c^*(\mathcal{E}) \subset \mathcal{K}^*(\mathcal{E}) \).
Lemma A.9.  (1) For any $\ast = \emptyset, -, +$, or $b$, a $\ast$-bounded complex over $E$ is acyclic if and only if it is homotopy equivalent to a $\ast$-bounded exact complex and if and only if it is a direct summand of a $\ast$-bounded exact complex.

(2) For any exact category $E$, the full subcategory $\Ac^\ast(E) \subset K^\ast(E)$ is thick.

(3) An exact category $E$ is saturated if and only if any acyclic complex over $E$ is exact. A complex over $E$ is acyclic if and only if it is exact as a complex over $E^{\text{sat}}$. For $\ast = -, +$, or $b$, an exact category $E$ is semi-saturated if and only if any $\ast$-bounded acyclic complex over $E$ is exact. A $\ast$-bounded complex over $E$ is acyclic if and only if it is exact as a complex over $E^{\text{sat}}$.

(4) For $\ast = \emptyset, -, +$, or $b$, the natural functor $K^\ast(E) \to K^\ast(E^{\text{sat}})$ is an equivalence of triangulated categories identifying $\Ac^\ast(E)$ with $\Ac^\ast(E^{\text{sat}})$. For any $\ast$, the natural functor $K^\ast(E) \to K^\ast(E^{\text{ss}})$ is an equivalence of triangulated categories identifying $\Ac^\ast(E)$ with $\Ac^\ast(E^{\text{ss}})$.

Proof. This lemma is just a somewhat more precise rephrasing of the results of [31]. Notice that the canonical truncations are defined for exact complexes over an exact category. In particular, any $\ast$-bounded complex homotopy equivalent to an exact complex is homotopy equivalent to a $\ast$-bounded exact complex.

If $X^\bullet$ is a $\ast$-bounded complex over $E$ homotopy equivalent to a $\ast$-bounded exact complex $Y^\bullet$ over $E$, then $X^\bullet$ is a direct summand of the $\ast$-bounded exact complex $Y^\bullet \oplus \text{Cone} (\text{id}_{X^\bullet})$ over $E$ [31]. Clearly, any direct summand of a $\ast$-bounded exact complex over $E^{\text{sat}}$ is itself a $\ast$-bounded exact complex over $E^{\text{sat}}$. If $X^\bullet$ is a $\ast$-bounded exact complex over $E^{\text{sat}}$, then there is a $\ast$-bounded contractible complex $Y^\bullet$ over $E^{\text{sat}}$ such that $X^\bullet \oplus Y^\bullet$ is an exact complex over $E$. It is easy to show this using the fact that $E$ is closed under extensions in $E^{\text{sat}}$. Consequently, $X^\bullet$ is homotopy equivalent to $X^\bullet \oplus Y^\bullet$. This suffices to prove parts (1–2), the second assertion of (3), the “if” part of the fourth assertion of (3), and the second parts of both assertions of (4).

Similarly one proves the first parts of the assertions of (4). The “if” parts of the first and third assertions of (3) are easy [31], and the “only if” parts are equivalent to the “only if” parts of the second and fourth assertions. Finally, the “only if” part of the third assertion of (3) follows by induction from axiom Ex2''(a–b) or the last two assertions of Proposition A.7.

Example A.10. Let $E$ and $E_i, i \in \mathbb{Z}$, be exact categories, $\Phi_i : E_i \to E$ be exact functors, and $F$ be the exact category of finitely filtered objects in $E$ with successive quotients lifted to $E_i$ as defined in Section 3. Then a complex $X^\bullet$ over $F$ is exact (acyclic) if and only if the complex of successive quotients $q_i(X^\bullet)$ is exact (acyclic) over $E_i$ for every $i \in \mathbb{Z}$. In particular, if the exact category structures on $E_i$ are trivial, then the complex $X^\bullet$ is acyclic if and only if all the complexes $q_i(X^\bullet)$ are contractible.

A morphism of complexes $X^\bullet \to Y^\bullet$ in $K(E)$ is called a quasi-isomorphism if its cone is acyclic. The (bounded or unbounded) derived categories of an exact category $E$ are defined as the triangulated quotient categories $D(E) = K(E)/Ac(E)$ or $D^\ast(E) = K^\ast(E)/Ac^\ast(E)$ for $\ast = -, +$, or $b$. We are not discussing the set-
Corollary A.11. For any exact category $\mathcal{E}$ and any $\ast = -, +$, or $b$, the natural functor $\mathcal{D}^\ast(\mathcal{E}) \to \mathcal{D}(\mathcal{E})$ is fully faithful.

Proof. This follows from Proposition A.8 and its dual version. □

Corollary A.12. For any small exact category $\mathcal{E}$, the functors $\mathcal{D}^-(\mathcal{E}) \to \mathcal{D}^-(\mathcal{A}'(\mathcal{E}))$ and $\mathcal{D}^+(\mathcal{E}) \to \mathcal{D}^+(\mathcal{A}''(\mathcal{E}))$ induced by the canonical embeddings $\rho': \mathcal{E} \to \mathcal{A}'(\mathcal{E})$ and $\rho'': \mathcal{E} \to \mathcal{A}''(\mathcal{E})$ are fully faithful.

Proof. This follows from the existence of canonical truncations of exact complexes. □

Let $\mathcal{E}$ be a small exact category. By the definition, we put $\text{Ext}^0_{\mathcal{E}}(X, Y) = \text{Hom}_{\mathcal{D}^0(\mathcal{E})}(X, Y[n])$. The composition of morphisms in the derived category defines multiplication maps $\text{Ext}^0_{\mathcal{E}}(Y, Z) \times \text{Ext}^0_{\mathcal{E}}(X, Y) \to \text{Ext}^0_{\mathcal{E}}(X, Y)$.

Proposition A.13. In any exact category $\mathcal{E}$, the Ext groups with negative numbers are zero, $\text{Ext}^n_{\mathcal{E}}(X, Y) = 0$ for $n < 0$. The natural morphism $\text{Hom}_{\mathcal{E}}(X, Y) \to \text{Ext}^0_{\mathcal{E}}(X, Y)$ is an isomorphism; in other words, the functor $\mathcal{E} \to \mathcal{D}^b(\mathcal{E})$ is fully faithful.

The Ext groups with positive numbers $n > 0$ are computed by the following Yoneda construction. Consider the set $\text{Yon}^{\ast n}_{\mathcal{E}}(X, Y)$ of all exact complexes $A^\ast$ over $\mathcal{E}$ such that $A^i = 0$ for all $i < 0$ and $i > n + 1$, $A^0 = Y$, and $A^{n+1} = X$. Two elements $A$ and $B$ in $\text{Yon}^{\ast n}_{\mathcal{E}}(X, Y)$ are said to be equivalent if there exists a third element $C \in \text{Yon}^{\ast n}_{\mathcal{E}}(X, Y)$ and two morphisms of complexes $C \to A$ and $C \to B$, both inducing identity morphisms on the terms $Y$ in degree $0$ and $X$ in degree $n + 1$. This is indeed an equivalence relation and the quotient set of the set of Yoneda extensions $\text{Yon}^{\ast n}_{\mathcal{E}}(X, Y)$ modulo this equivalence relation is canonically bijective to $\text{Ext}^n_{\mathcal{E}}(X, Y)$. Alternatively, one can use morphisms of exact complexes going in the opposite direction, $A \to C$ and $B \to C$; this defines the same equivalence relation.

The addition in the Ext groups is given by the Baer sum construction. The multiplication on the Ext groups corresponds to the obvious composition operation on the Yoneda extensions.

Proof. This follows from the construction of the triangulated quotient category [48] and the existence of canonical truncations of exact complexes. □

Another important explicit construction of the higher Ext groups in an exact category is provided by Corollary A.16.

Corollary A.14. The product of the elements in $\text{Ext}^1_{\mathcal{E}}(X, Z)$ and $\text{Ext}^1_{\mathcal{E}}(Z, Y)$ corresponding to admissible triples $Z \to V \to X$ and $Y \to U \to Z$ in $\mathcal{E}$ vanishes in $\text{Ext}^2_{\mathcal{E}}(X, Y)$ if and only if the composition of morphisms $U \to Z \to V$ can be factorized as $U \to T \to V$ in such a way that the triples $Y \to T \to V$ and $U \to T \to X$ are admissible in $\mathcal{E}$.

Proof. This is most simply deduced from the long exact sequence of Ext groups corresponding to an admissible triple, which in turn follows from the definition of $\text{Ext}_{\mathcal{E}}$ in terms of morphisms in $\mathcal{D}^b(\mathcal{E})$. □
An object of an exact category is called \textit{projective (injective)} if the functor of morphisms from (into) this objects sends admissible triples to short exact sequences. A projective (injective) \textit{resolution} of an object, or a complex of objects, in an exact category is a bounded above (below) complex of projective (injective) objects endowed with a quasi-isomorphism into (from) the given object or complex. Since any morphism into (from) an acyclic complex from (into) a bounded above (below) complex of projective (injective) objects is homotopic to zero, one can use projective (injective) resolutions to compute the groups $\text{Ext}$ in an exact category.

\textbf{A.8. Exact subcategories of triangulated categories.} A full subcategory $\mathcal{E}$ of a triangulated category $\mathcal{D}$ is called an \textit{exact subcategory} if $\text{Hom}_D(X, Z[-1]) = 0$ for all $X, Z \in \mathcal{D}$ and the class of all triples $X \to Y \to Z$ in $\mathcal{E}$ that can be embedded into a distinguished triangle $X \to Y \to Z \to X[1]$ in $\mathcal{D}$ defines an exact category structure on $\mathcal{E}$. Notice that the former condition guarantees that the distinguished triangle in the latter condition is unique if it exists. Axioms Ex0 and Ex1 are satisfied automatically by the class of admissible triples defined in the above way; it is only axioms Ex2 and Ex3 that have to be checked.

A full subcategory $\mathcal{E}$ in a triangulated category $\mathcal{D}$ is said to be \textit{closed under extensions} if it contains the middle term $Y$ of any distinguished triangle $X \to Y \to Z \to X[1]$ with $X, Z \in \mathcal{E}$. Any full subcategory $\mathcal{E} \subset \mathcal{D}$ that is closed under extensions and satisfies the condition that $\text{Hom}_D(X, Z[-1]) = 0$ for all $X, Z \in \mathcal{E}$ is an exact subcategory of $\mathcal{D}$ \cite{18}. One applies the octahedron axiom in $\mathcal{D}$ in order to show that axioms Ex2 and Ex3 hold in $\mathcal{E}$.

In particular, it follows from the description of $\text{Ext}_2^n$ in Proposition A.13 for $n = -1, 0, 1$ that any exact category $\mathcal{E}$ is an exact subcategory, closed under extensions, in its derived category $\mathcal{D}^b(\mathcal{E})$. For any exact subcategory $\mathcal{E}$ in a triangulated category $\mathcal{D}$, there is a natural injective map of abelian groups $\text{Ext}_2^1(X, Z) \to \text{Hom}_D(X, Z[1])$ for all $X, Z \in \mathcal{E}$ assigning to an admissible triple $X \to Y \to Z$ in $\mathcal{E}$ the rightmost map of the distinguished triangle $X \to Y \to Z \to Y[1]$. To check additivity, one can consider the direct sum of two copies of either $X$ or $Z$ and use the functoriality, which is verified using the condition of vanishing of $\text{Hom}_D(X, Z[-1])$. The maps $\text{Ext}_2^1(X, Z) \to \text{Hom}_D(X, Z[1])$ are isomorphisms for all $X, Z \in \mathcal{E}$ if and only if the subcategory $\mathcal{E}$ is closed under extensions in $\mathcal{D}$.

Let $\mathcal{E} \subset \mathcal{D}$ be a small exact subcategory in a triangulated category. Consider the big graded ring of higher Hom groups

$$\mathcal{H}(\mathcal{E}, \mathcal{D}) = \bigoplus_{n=0}^{\infty} \mathcal{H}^n(\mathcal{E}, \mathcal{D}); \quad \mathcal{H}^n(\mathcal{E}, \mathcal{D}) = (\text{Hom}_D(X, Y[n]))_{Y, X \in \mathcal{E}}.$$  

Let $\mathcal{H}(\mathcal{E}) = \mathcal{H}(\mathcal{E}, \mathcal{D}^b(\mathcal{E}))$ denote the big graded ring of Ext groups in an exact category $\mathcal{E}$. There is a natural isomorphism of big rings $\mathcal{H}^0(\mathcal{E}) \simeq \mathcal{H}^0(\mathcal{E}, \mathcal{D})$ and a natural injective morphism of bimodules $\mathcal{H}^1(\mathcal{E}) \to \mathcal{H}^1(\mathcal{E}, \mathcal{D})$.

\textbf{Proposition A.15.} \textit{For any small exact subcategory $\mathcal{E}$ in a triangulated category $\mathcal{D}$, the multiplication maps $\mathcal{H}^1(\mathcal{E}) \otimes_{\mathcal{H}^0(\mathcal{E})} \mathcal{H}^n(\mathcal{E}, \mathcal{D}) \to \mathcal{H}^{n+1}(\mathcal{E}, \mathcal{D})$ and $\mathcal{H}^n(\mathcal{E}, \mathcal{D}) \otimes_{\mathcal{H}^0(\mathcal{E})} \mathcal{H}^1(\mathcal{E}) \to \mathcal{H}^{n+1}(\mathcal{E}, \mathcal{D})$ are injective for all $n \geq 0$.}

\textit{Proof.} It is easy to check using the existence of finite direct sums in the category $\mathcal{E}$ that any element of $\mathcal{H}^1(\mathcal{E}) \otimes_{\mathcal{H}^0(\mathcal{E})} \mathcal{H}^n(\mathcal{E}, \mathcal{D})$ has the form $\xi \otimes \eta$ for some $\xi \in \mathcal{H}^1(\mathcal{E})$ and $\eta \in \mathcal{H}^n(\mathcal{E}, \mathcal{D})$. The result follows. 

\textit{Remark.} One can show that $\mathcal{H}(\mathcal{E})$ is a subring of $\mathcal{H}(\mathcal{E}, \mathcal{D})$. For the proof, it suffices to check that $\mathcal{H}^0(\mathcal{E})$ is a subring of $\mathcal{H}^0(\mathcal{E}, \mathcal{D})$. This is straightforward. 

\textit{Proof.} It is easy to check using the existence of finite direct sums in the category $\mathcal{E}$ that any element of $\mathcal{H}^1(\mathcal{E}) \otimes_{\mathcal{H}^0(\mathcal{E})} \mathcal{H}^n(\mathcal{E}, \mathcal{D})$ has the form $\xi \otimes \eta$ for some $\xi \in \mathcal{H}^1(\mathcal{E})$ and $\eta \in \mathcal{H}^n(\mathcal{E}, \mathcal{D})$. The result follows.
$\text{Ext}^1_{\mathcal{E}}(Y, Z)$ and $\eta \in \text{Hom}_D(X, Y[n])$. Consider the distinguished triangle $Z \to T \xrightarrow{\xi} Y \to Z[1]$ in $D$ corresponding to the admissible triple $Z \to T \to Y$ in $\mathcal{E}$ representing $\xi$; we will denote the morphism $Y \to Z[1]$ also by $\xi$. Now if the composition $\xi \circ \eta : X \to Z[n + 1]$ is zero, there exists a morphism $\eta' : X \to T[n]$ such that $\eta = f \circ \eta'$. Then we have $\xi \otimes \eta = \xi \otimes f \eta' = \xi f \otimes \eta' = 0$ in the group $H^1(\mathcal{E}) \otimes_{H^0(\mathcal{E})} H^n(\mathcal{E}, D)$.

**Corollary A.16.** For any small exact category $\mathcal{E}$, the big graded ring of Ext groups $H = H(\mathcal{E})$ is a free big graded ring generated by the $H^0$-bimodule $H^1$, that is the multiplication morphisms $H^1 \otimes_{H^0} H^1 \to H^0$ are isomorphisms.

**Proof.** The morphisms $H^1 \otimes_{H^0} H^n \to H^{n+1}$ are injective by the above proposition and surjective by Proposition A.13. □

**Corollary A.17.** For any exact subcategory $\mathcal{E}$ in a triangulated category $D$, there exists a unique sequence of morphisms of functors of two arguments $\mathcal{E}^{op} \times \mathcal{E} \to \text{Ab}$

$$\theta^n = \theta^n_{\mathcal{E}, D} : \text{Ext}^n_{\mathcal{E}}(X, Y) \to \text{Hom}_D(X, Y[n]), \quad n \geq 0,$$

with the following properties: the maps $\theta^n$ are compatible with the composition, the map $\theta^0$ is the identity, and the map $\theta^1$ sends the Yoneda class of an admissible triple $Y \to T \to X$ in the exact category $\mathcal{E}$ to the third arrow $X \to Y[1]$ of the corresponding distinguished triangle in the triangulated category $D$.

Moreover, if the morphism of functors $\theta^n_{\mathcal{E}, D}$ is an isomorphism for a certain $n \geq 0$, then all the maps $\theta^n_{\mathcal{E}, D}$ are injective. In particular, if $\mathcal{E}$ is closed under extensions in $D$, then $\theta^1_{\mathcal{E}, D}$ is an isomorphism and $\theta^n_{\mathcal{E}, D}$ is injective; if all the maps $\theta^n$ are surjective for $n \leq m$, then all of them are isomorphisms.

**Proof.** Existence and uniqueness follow from Corollary A.16; alternatively, one can use the universal property of effaceable homological functors (see [22]). Injectivity follows from the proposition. □

**Corollary A.18.** Let $\mathcal{A}$ be an exact category and $\mathcal{E}$ be its full exact subcategory closed under extensions and such that any object of $\mathcal{A}$ is a direct summand of an object of $\mathcal{E}$ (see Section A.5(6)). Then the natural maps $\text{Ext}^n_{\mathcal{E}}(X, Y) \to \text{Ext}^n_{\mathcal{A}}(X, Y)$ are isomorphisms for all $X, Y \in \mathcal{E}$ and $n \geq 0$.

A full subcategory $\mathcal{A}$ in a triangulated category $D$ is the heart of a bounded $t$-structure on $D$ if and only if $\mathcal{A}$ is closed under extensions, $\text{Hom}_D(X, Y[n]) = 0$ for all $X, Y \in \mathcal{A}$ and $n < 0$, the exact category structure on $\mathcal{A}$ is the canonical exact category structure of an abelian category, and the triangulated category $D$ is generated by $\mathcal{A}$ [4, Proposition 1.3.13]. Thus all the above results are applicable in the case when $\mathcal{E} = \mathcal{A}$ is the heart of a $t$-structure on a triangulated category $D$.

**Appendix B. Silly Filtrations**

The results of this appendix elaborate on the condition that the morphisms $\theta^n_{\mathcal{E}, D}$ of Corollary A.17 are surjective (or equivalently, isomorphisms) for an exact subcategory $\mathcal{E} \subset D$ closed under extensions. It turns out that one does not have to assume that the groups $\text{Hom}(X, Y[−1])$ are zero in order to discuss this condition.
We will freely use the *-operation notation for classes of objects in triangulated categories [4, 1.3.9–10]. Besides, will use the notation of Section A.2 related to semi-saturated completions and saturated closures.

**Proposition B.1.** Let $\mathcal{D}$ be a triangulated category, $\mathcal{A} \subset \mathcal{D}$ be a full subcategory, and $\mathcal{M} = \bigcup_m \mathcal{A}^m \subset \mathcal{D}$ be the minimal full subcategory containing $\mathcal{A}$ and closed under extensions. Then for any $n \geq 2$ the following three conditions are equivalent:

(a) Any morphism $X \to Y[k]$ with $2 \leq k \leq n$ between two objects $X, Y \in \mathcal{M}$ can be presented as the composition of a chain of morphisms $Z_{i-1} \to Z_i[1]$ with $Z_i \in \mathcal{M}$, $Z_0 = X$, and $Z_k = Y$.

(b) Any morphism $\mathcal{A} \to Y[k]$ with $2 \leq k \leq n$ between two objects $\mathcal{A} \in \mathcal{A}$ and $Y \in \mathcal{M}$ can be presented as the composition of a morphism $\mathcal{A} \to Z[1]$ and a morphism $Z[1] \to Y[k]$ such that $Z \in \mathcal{M}$.

(c) Any morphism $\mathcal{A} \to Y[k]$ with $2 \leq k \leq n$ between two objects $A \in \mathcal{A}$ and $Y \in \mathcal{M}$ can be presented as the composition of a morphism $\mathcal{A} \to Z[k-1]$ and a morphism $Z[k-1] \to Y[k]$ such that $Z \in \mathcal{M}$.

Furthermore, any of the next two conditions implies the previous three:

(d) Any morphism $\mathcal{A} \to B[k]$ with $2 \leq k \leq n$ between two objects $A, B \in \mathcal{A}$ can be presented as the composition of a morphism $\mathcal{A} \to Z[1]$ and a morphism $Z[1] \to B[k]$ such that $Z \in \mathcal{M}$ and a cone of the morphism $\mathcal{A} \to Z[1]$ belongs to $\mathcal{A}[1]$.

(e) Any morphism $\mathcal{A} \to Y[k]$ with $2 \leq k \leq n$ between two objects $A, B \in \mathcal{A}$ can be presented as the composition of a morphism $\mathcal{A} \to Z[k-1]$ and a morphism $Z[k-1] \to B[k]$ such that $Z \in \mathcal{M}$ and a cone of the morphism $Z[k-1] \to B[k]$ belongs to $\mathcal{A}[k]$.

**Proof.** A simple induction on $n$ proves (c) $\implies$ (b); including the equivalence of (a–c) for $k \leq n - 1$ in the induction assumption, we obtain (b) $\implies$ (c). It is obvious that (a) implies (b) and (c).

To prove (c) $\implies$ (a), reformulate (c) as the assertion that for any morphism $\mathcal{A} \to Y[k]$ with $A \in \mathcal{A}$ and $Y \in \mathcal{M}$ there exists a distinguished triangle $Y[k] \to W[k] \to Z[k] \to Y[k+1]$ with $Z \in \mathcal{M}$ such that the composition $\mathcal{A} \to Y[k] \to W[k]$ vanishes. The condition (a) can be restated as the similar assertion with $A \in \mathcal{A}$ replaced by $X \in \mathcal{M}$. Let $A_1 \to A \to A_2 \to A_1[1]$ be a distinguished triangle in $\mathcal{D}$. Assuming that both objects $A_1$ and $A_2$ have the above property for any morphism $A_1 \to Y[k]$ with $Y \in \mathcal{M}$, we will show that the object $A$ has the same property. Let $A \to Y[k]$ be any morphism; consider the composition $A_1 \to A \to Y[k]$. Then there exists a distinguished triangle $Y[k] \to W_1[k] \to Z_1[k]$ with $Z_1 \in \mathcal{M}$ such that the composition $A_1 \to A \to Y[k] \to W_1[k]$ vanishes. Hence the composition $A \to Y[k] \to W_1[k]$ factorizes through the morphism $A \to A_2$. Consider the morphism $A_1 \to W_1[k]$ that we have obtained. There exists a distinguished triangle $W_1[k] \to W[k] \to Z_2[k] \to W_1[k+1]$ with $Z_2 \in \mathcal{M}$ such that the composition $A_2 \to W_1[k] \to W[k]$ vanishes. Then the composition $A \to Y[k] \to W_1[k] \to W[k]$ also vanishes. By the octahedron axiom, the cone of the composition $Y[k] \to W_1[k] \to W[k]$ is an extension of $Z_2[k]$ and $Z_1[k]$, so it belongs to $\mathcal{M}[k]$. 

To prove (d) \(\Rightarrow\) (b), reformulate (d) as the assertion that for any morphism \(A \to B[k]\) with \(A, B \in A\) there exists a distinguished triangle \(Z \to C \to A \to W[1]\) with \(Z \in \mathcal{M}\) and \(C \in A\) such that the composition \(C \to A \to B[k]\) vanishes. Then argue as above. Now we know that (d) \(\Rightarrow\) (a), and the implication (e) \(\Rightarrow\) (a) follows by duality. □

**Proposition B.2.** Let \(D\) be a triangulated category and \(\mathcal{M} \subset \mathcal{D}\) be a full subcategory closed under extensions. Then any morphism \(X \to Y[n]\) with \(n \geq 2\) between two objects \(X, Y \in \mathcal{D}\) can be presented as the composition of a chain of morphisms \(Z \to C \to A \to B[k]\) with \(Z \in \mathcal{M}\) and \(C \in A\) such that the composition \(C \to A \to B[k]\) vanishes. Then argue as above. Now we know that (d) \(\Rightarrow\) (a), and the implication (e) \(\Rightarrow\) (a) follows by duality.

**Proposition B.2.** Let \(D\) be a triangulated category and \(\mathcal{M} \subset \mathcal{D}\) be a full subcategory closed under extensions. Then any morphism \(X \to Y[n]\) with \(n \geq 2\) between two objects \(X, Y \in \mathcal{D}\) can be presented as the composition of a chain of morphisms \(Z \to C \to A \to B[k]\) with \(Z \in \mathcal{M}\) and \(C \in A\) such that the composition \(C \to A \to B[k]\) vanishes. Then argue as above. Now we know that (d) \(\Rightarrow\) (a), and the implication (e) \(\Rightarrow\) (a) follows by duality.

The key ideas of the proof are summarized in the following lemma.

**Lemma B.3.** Let \(D\) be a triangulated category. Then

(1) Suppose that a morphism \(f: A \to B\) in \(D\) factorizes through an object \(E\). Then \(\{B\} \ast \{A[1]\} \ni \text{Cone}(f) \in \{E\} \ast \{A[1]\} \ast \{B\} \ast \{E[1]\}\).

(2) Suppose that the cones of two morphisms \(A \to B\) and \(C \to D\) are isomorphic in \(D\). Then both morphisms factorize through an object \(E\) belonging to the intersection \(\{A\} \ast \{D\} \cap \{C\} \ast \{B\}\).

(3) Suppose that an object \(W\) is a direct summand of an extension of objects \(A\) and \(D\) and also a direct summand of an extension of objects \(C\) and \(B\). Then, in particular, there are morphisms \(A \to W\) and \(W \to B\); suppose moreover, that their composition factorizes through an object \(E\). Then \(W\) is a direct summand of an object in \(\{C\} \ast \{E\} \ast \{E\} \ast \{D\}\).

**Proof.** Part (1): Consider the distinguished triangles

\[
A \to E \to D \to A[1],
\]

\[
B[-1] \to C \to E \to B.
\]

By the octahedron axiom, there are also distinguished triangles

\[
A \to B \to K \to A[1],
\]

\[
C \to D \to K \to C[1].
\]

So \(D \in \{E\} \ast \{A[1]\}\) and \(C[1] \in \{B\} \ast \{E[1]\}\), hence

\[
\{B\} \ast \{A[1]\} \ni K \in \{D\} \ast \{C[1]\} \subset \{E\} \ast \{A[1]\} \ast \{B\} \ast \{E[1]\}.
\]

Part (2): By the octahedron axiom, there exist four distinguished triangles as above and the morphisms \(A \to B\) and \(C \to D\) factorize through \(E\). Clearly, \(E \in \{A\} \ast \{D\} \cap \{C\} \ast \{B\}\).
Part (3): By our assumption, there exist objects $S, T \in \mathcal{D}$ and distinguished triangles

\[
\begin{align*}
A &\rightarrow S \oplus W \rightarrow D \rightarrow A[1] \\
B[-1] &\rightarrow C \rightarrow T \oplus W \rightarrow B.
\end{align*}
\]

Combining the given morphisms with appropriate signs, we get a pair of morphisms $A \rightarrow S \oplus T \oplus W \oplus E \rightarrow B$ with zero composition. There are distinguished triangles

\[
\begin{align*}
A &\rightarrow S \oplus T \oplus W \oplus E \rightarrow T \oplus K \rightarrow A[1] \\
E &\rightarrow K \rightarrow D \rightarrow E[1]
\end{align*}
\]

and

\[
\begin{align*}
S \oplus L &\rightarrow S \oplus T \oplus W \oplus E \rightarrow B \rightarrow S[1] \oplus L[1] \\
C &\rightarrow L \rightarrow E \rightarrow C[1]
\end{align*}
\]

and a pair of morphisms $A \rightarrow S \oplus L, T \oplus K \rightarrow B$ forming a morphism of distinguished triangles with a common vertex $S \oplus T \oplus W \oplus E$. Applying the octahedron axiom, we obtain distinguished triangles

\[
\begin{align*}
A &\rightarrow S \oplus L \rightarrow F \rightarrow A[1] \\
F &\rightarrow T \oplus K \rightarrow B \rightarrow F[1]
\end{align*}
\]

Finally, there is a morphism $T \oplus K \rightarrow S[1] \oplus L[1]$ that can be obtained as the composition $T \oplus K \rightarrow A[1] \rightarrow S[1] \oplus L[1]$ or $T \oplus K \rightarrow B \rightarrow S[1] \oplus L[1]$. This morphism can be included in the distinguished triangle

\[
T[-1] \oplus K[-1] \rightarrow S \oplus L \rightarrow S \oplus T \oplus W \oplus E \oplus F \rightarrow T \oplus K,
\]

where the morphisms $S \rightarrow S \oplus T \oplus W \oplus E \rightarrow T$ are just the obvious embedding and projection, while the components $L \rightarrow S$ and $T \rightarrow K$ vanish. Hence we obtain the distinguished triangle

\[
K[-1] \rightarrow L \rightarrow W \oplus E \oplus F \rightarrow K.
\]

Now $L \in \{C\} \ast \{E\}$ and $K \in \{E\} \ast \{D\}$, hence $W \oplus E \oplus F \in \{L\} \ast \{K\} \subset \{C\} \ast \{E\} \ast \{E\} \ast \{D\}$.

\[\square\]

Proof of Proposition B.2. First let us check the implication “if”. Let $X, Y \in \mathcal{M}$, and $f: X \rightarrow Y[n + 1]$ be a morphism in $\mathcal{D}$, where $n \geq 1$. Consider the object $Z = \text{Cone}(f[-1])$; then there is a distinguished triangle

\[
Y[n] \rightarrow Z \rightarrow X \rightarrow Y[n + 1],
\]

so $Z \in \mathcal{M}[n] \ast \mathcal{M}$. By (i), there exists a distinguished triangle

\[
U \rightarrow Z \rightarrow V \rightarrow U[1],
\]

where $U \in \mathcal{M}$ and $V \in \mathcal{M}[1] \ast \cdots \ast \mathcal{M}[n]$. So $Z$ is also a cone of the morphism $V[-1] \rightarrow U$. According to part (2) of Lemma B.3, the morphism $f[-1]$ factorizes through an object $E \in \{X[-1]\} \ast \{U\} \cap \{V[-1]\} \ast \{Y[n]\} \subset (\mathcal{M}[-1] \ast \mathcal{M}) \cap (\mathcal{M} \ast \cdots \ast \mathcal{M}[n])$. By (ii), $E \in \mathcal{M}_D^{\text{nat}}$. Now the morphism $f$ factorizes through $E[1]$, thus it also factorizes through an object of $\mathcal{M}[1]$.

It is not difficult to prove by induction that the minimal subcategory of $\mathcal{D}$ containing $\mathcal{M}, \ldots, \mathcal{M}[n]$ and closed under extensions coincides with $\mathcal{M} \ast \cdots \ast \mathcal{M}[n]$.
for any $n \geq 0$ provided that (i) holds. Specifically, one proceeds by induction on $n$, and then in the number of factors $\mathcal{M}[i]$ with the largest possible value $i = n$ in an iterated extension. This proves the last assertion of the proposition.

Now let us prove “only if”. To verify (i), consider an object $Z \in \mathcal{M}[n] \ast \mathcal{M}$. As above, we have $Z = \text{Cone}(f[-1])$ for some morphism $f : X \rightarrow Y[n + 1]$, where $X,Y \in \mathcal{M}$. Decompose the morphism $f$ as $X \rightarrow E[1] \rightarrow Y[n + 1]$, where $E \in \mathcal{M}$. By part (1) of Lemma B.3, $Z \in \{E\} \ast \{X\} \ast \{Y[n]\} \ast \{E[1]\} \subset \mathcal{M} \ast \mathcal{M} \ast \mathcal{M}[n] \ast \mathcal{M}[1]$. A simple induction on $n$ finishes the proof of (i).

To prove (ii), let us first check that

$$(\mathcal{M}[-1] \ast \cdots \ast \mathcal{M}[n-1])_{\text{sat}} \cap (\mathcal{M} \ast \cdots \ast \mathcal{M}[n])_{\text{sat}} \subset (\mathcal{M} \ast \cdots \ast \mathcal{M}[n-1])_{\text{sat}}.$$  

Let $W$ be an object in the intersection; then $W$ is a direct summand of an extension of $A = X[-1] \in \mathcal{M}[-1]$ and $B \in \mathcal{M} \ast \cdots \ast \mathcal{M}[n-1]$ and also a direct summand of an extension of $C \in \mathcal{M} \ast \cdots \ast \mathcal{M}[n-1]$ and $B = Y[n] \in \mathcal{M}[n]$. The morphism $A \rightarrow B$ factorizes through an object $E \in \mathcal{M}$. According to part (3) of Lemma B.3, $W$ is a direct summand of an object from $\{C\} \ast \{E\} \ast \{D\} \subset \mathcal{M} \ast \cdots \ast \mathcal{M}[n-1] \ast \mathcal{M} \ast \mathcal{M} \ast \cdots \ast \mathcal{M}[n-1]$. Thus $W \in (\mathcal{M} \ast \cdots \ast \mathcal{M}[n-1])_{\text{sat}}$. A simple induction allows to deduce (ii).

In some cases the condition (ii) is satisfied automatically. First of all, it always holds when $\mathcal{M}$ is the heart of a $t$-structure on $\mathcal{D}$ (see below). Secondly, it holds in the filtered case described in the next proposition.

**Proposition B.4.** Let $\mathcal{D}$ be a triangulated category endowed with a sequence of triangulated subcategories $\mathcal{D}_i \subset \mathcal{D}$, $i \in \mathbb{Z}$, such that $\text{Hom}_\mathcal{D}(X, Y) = 0$ for any $X \in \mathcal{D}_i$ and $Y \in \mathcal{D}_j$ with $i > j$. Let $\mathcal{M}_i \subset \mathcal{D}_i$ be full subcategories closed under extensions. Then the minimal full subcategory containing all $\mathcal{M}_i$ and closed under extensions

$\mathcal{M} = \bigcup_{i \leq j} \mathcal{M}_i \ast \cdots \ast \mathcal{M}_i \subset \mathcal{D}$

satisfies the condition (ii) of Proposition B.2 for $a = b$ if and only if all the subcategories $\mathcal{M}_i \subset \mathcal{D}_i$ do. Consequently, if $\mathcal{M}_i \subset \mathcal{D}_i$ satisfy (ii) for $a = b$ and $\mathcal{M} \subset \mathcal{D}$ satisfies (i), then $\mathcal{M}$ also satisfies (ii).

Furthermore, if all $\mathcal{M}_i \subset \mathcal{D}_i$ satisfy the following stronger version of condition (ii), then so does $\mathcal{M} \subset \mathcal{D}$:

$(\text{ii})'$ For any $a \leq b$ and $c \leq d$, the intersection of $\mathcal{M}^{[a,b]}$ with the minimal full subcategory of $\mathcal{D}$, containing $\mathcal{M}[-c]$, ..., $\mathcal{M}[-d]$ and closed under extensions is equal to $\mathcal{M}^{[a,b][c,d]}$, where $[a, b] \cap [c, d]$ is the intersection of the segments $[a, b]$ and $[c, d]$ in $\mathbb{Z}$.

**Proof.** To verify the first assertion, it suffices to consider the associated graded object functors $\mathcal{D} \rightarrow \mathcal{D}_i$. The second one follows from Proposition B.2 and its proof in the “if” direction, which only uses (ii) for $a = b$. To prove the last assertion, let us show that the intersection of $\mathcal{M}[-1] \ast \cdots \ast \mathcal{M}[n]$ with the minimal full subcategory of $\mathcal{D}$, containing $\mathcal{M}[k]$ for $k \geq 0$ and closed under extensions coincides with $\mathcal{M} \ast \cdots \ast \mathcal{M}[n]$. Let $W \in \mathcal{M}[-1] \ast \cdots \ast \mathcal{M}[n]$, then there exists a distinguished triangle

$$V[-1] \rightarrow U \rightarrow W \rightarrow V$$

with $U \in \mathcal{M}[-1] \ast \mathcal{M}$ and $V \in \mathcal{M}[1] \ast \cdots \ast \mathcal{M}[n]$. Assume that $W$ belongs to the minimal full subcategory of $\mathcal{D}$, containing $\mathcal{M}[k]$ for $k \geq 0$ and closed under
extensions; then, since \( U \in \{ V[-1] \} \ast \{ W \} \), so does \( U \). By our assumption, the images \( U_i \) of the object \( U \) under the functors of associated graded objects \( D \to D_i \) belong to \( M_i \). Thus \( U \in M \) and \( W \in M \ast \cdots \ast M[\nu] \). The dual argument shows that the intersection of \( M[-n] \ast \cdots \ast M[\mu] \) with the minimal full subcategory of \( D \), containing \( M[k] \) for \( k \leq 0 \) and closed under extensions coincides with \( M[-n] \ast \cdots \ast M \).

**Example B.5.** The following counterexample shows, however, that the condition (ii) does not always hold for an exact subcategory \( M \subset D \), and moreover, (i) does not imply (ii) in this case. Let \( B \) be the abelian category of 3-term complexes of vector spaces \( V^{(1)} \to V^{(2)} \to V^{(3)} \) (the composition of the two arrows must be zero). There are 5 indecomposable objects in this category, denoted \( E_1, E_2, E_3, E_{12}, E_{23} \) (see Example A.6). Let \( M \subset B \) be the full additive subcategory whose objects are the direct sums of all the indecomposables except \( E_2 \). Set \( D = D^b(B) \). Then \( M \) is closed under extensions in \( B \) and \( D \) and inherits a trivial exact category structure, i.e., all the exact triples in \( M \) are split. One can check that \( M \) generates \( D \) and satisfies (i), but not (ii).

Furthermore, under the assumptions similar to those mentioned above the condition (i) allows a very simple reformulation.

**Proposition B.6.** Let \( D \) be a triangulated category and \( M \subset D \) be a full subcategory closed under extensions. Assume that we are in one of the following two situations:

(a) \( M \) is the heart of a bounded t-structure on \( D \).

(b) \( D \) is endowed with a sequence of triangulated subcategories \( D_i \subset D \), \( i \in \mathbb{Z} \), such that \( \text{Hom}_D(X, Y) = 0 \) for any \( X \in D_i \) and \( Y \in D_j \) with \( i > j \). Each \( D_i \) is equivalent to the bounded derived category \( D^b(M_i) \) of an exact category \( M_i \). The subcategory \( M \subset D \) is the minimal full subcategory containing all \( M_i \) and closed under extensions, \( M = \bigcup_{i \geq j} M_j \ast \cdots \ast M_i \).

Then the condition (ii) of Proposition B.2 always holds and (i) is equivalent to its following weaker form:

\[(i') \ D = \bigcup_{a, b} M^{[a, b]} \text{, where } M^{[a, b]} = M[-b] \ast \cdots \ast M[-a] \text{ for any } a \leq b.\]

**Proof.** In the case (b), according to Lemma A.9(4), \( D_i \simeq D^b(M_i^{\text{ss}}) \). Clearly, the condition (ii) does not become weaker when one replaces \( M_i \) with \( M_i^{\text{ss}} \) and \( M \) with \( M^{\text{ss}} \). According to Proposition B.2, the sum total of the conditions (i) and (ii) does not change, either. So we can assume that \( M_i \) are semi-saturated. With this assumption, in both cases (a) and (b) we will prove the condition (ii') of Proposition B.4. Clearly, it implies both (ii) and (i') \( \Rightarrow \) (i).

According to Proposition B.4, in the case (b) it suffices to consider the case when \( D = D_i = D^b(M_i) \) and \( M = M_i \).

As demonstrated in the proof of Proposition B.4, it suffices to show that the intersection of \( M[-1] \ast M \) with the minimal full subcategory of \( D \), containing \( M[k] \) for \( k \geq 0 \) and closed under extensions coincides with \( M \). Let \( U \in M[-1] \ast M \); then there is a distinguished triangle

\[X[-1] \to Y[-1] \to U \to X\]
with $X, Y \in \mathcal{M}$. Assume that $U$ belongs to the minimal full subcategory of $\mathcal{D}$, containing $\mathcal{M}[k]$ for $k \geq 0$ and closed under extensions. In the case (a), we have $U \in \mathcal{D}^{\leq 0}$, and it follows immediately from the long exact sequence of $t$-cohomology [4, Théorème 1.3.6] that the morphism $X \to Y$ is surjective. In the case (b), using, e. g., Corollary A.12 and Proposition A.7, we can conclude that the morphism $X \to Y$ is an admissible epimorphism. Another way is to use the existence of canonical truncations of exact complexes over $\mathcal{M}$ and axiom Ex2"(b). Alternatively, one can use Proposition B.2 in order to conclude that $U \in \mathcal{M}_{\mathcal{D}}$ sat $\mathcal{D}$, and then deduce the assertion that $X \to Y$ is an admissible epimorphism in $\mathcal{M}$ from the facts that it is such in $\mathcal{M}_{\mathcal{D}}$ and the category $\mathcal{M}$ is semi-saturated.

In both cases it follows that $U \in \mathcal{M}$. □

Appendix C. Classical $\mathbf{K}(\pi, 1)$ Conjecture

Let $k$ be a commutative ring and $A$ be DG-algebra over $k$ endowed with two $\mathbb{Z}$-valued grading, called the internal and the cohomological gradings [39, Appendix A]. The differential in $A$ raises the cohomological grading by 1 and preserves the internal grading; it also satisfies the super-Leibniz rule with respect to the cohomological grading. The cohomological grading is denoted by the upper indices and the internal grading by the lower ones. Let $X \mapsto X[1]$ denote the shift of cohomological grading of internally graded complexes by 1 down (as usually) and $X \mapsto X(1)$ denote the shift of their internal grading by 1 up. For an internally graded complex $M$ of $k$-modules with the differential $d$, let $H^n(M)$ denote its internally graded $k$-module of cohomology of $M$ with respect to $d$ in the cohomological degree $n$.

Assume further that $A$ (with the differential forgotten) is a flat bigraded $k$-module, that $A_i = 0$ for $i > 0$, and the complex $A_0$ is concentrated in the cohomological degree 0 and freely generated as a $k$-module by the unit element of $A$. We will also consider internally graded DG-coalgebras $C$ over $k$ satisfying the same list of conditions, except that the counit map $C_0 \to k$ is an isomorphism of complexes. The reduced bar- and cobar-constructions assign to an algebra $A$ of the above kind a coalgebra $C$ of the above kind and vice versa; these constructions preserve quasi-isomorphisms of algebras and coalgebras and are mutually inverse up to natural quasi-isomorphisms [39, Theorem A.1.1 and Remark A.1].

Let $\mathcal{D}(A\text{-mod})$ denote the derived category of internally graded left DG-modules over $A$. We are interested in the triangulated subcategory $\mathcal{D} \subset \mathcal{D}(A\text{-mod})$ generated by the free DG-modules $A(i)$, $i \in \mathbb{Z}$. Let $C$ be the reduced bar-construction of $A$ and $\mathcal{D}(C\text{-comod})$ be the derived category of internally graded left DG-comodules over $C$. No $k$-flatness conditions are imposed on the terms of DG-(co)modules. The categories $\mathcal{D}(A\text{-mod})$ and $\mathcal{D}(C\text{-comod})$ are not equivalent in general; however, their full subcategories formed by DG-modules and DG-comodules with cohomology bounded from above in the internal grading are equivalent [39, Theorem A.1.2 and Remark A.1]. It follows that the category $\mathcal{D}$ is equivalent to the full triangulated subcategory of $\mathcal{D}(C\text{-comod})$ generated by the trivial DG-comodules $k(i)$; the equivalence sends $A(i)$ to $k(i)$. Let $\mathcal{M}$ denote the minimal full subcategory of $\mathcal{D}$ containing the DG-modules $A(i)$ (or the DG-comodules $k(i)$) and closed under extensions.
C.1. Positive cohomology. Assume that the ring $k$ is Noetherian and has a finite homological dimension. Then the triangulated subcategory $D \subset D(C\text{-comod})$ can be equivalently defined as the subcategory of all DG-comodules whose bigraded $k$-modules of cohomology are finitely generated.

**Theorem C.1.** One has $H^n(C) = 0$ for all $n > 0$ if and only if any morphism $X \to Y[n]$ of degree $n \geq 2$ in $D$ between two objects $X, Y \in M$ can be presented as the composition of a chain of morphisms $Z_{i-1} \to Z_i[1]$ with $Z_i \in M$, $Z_0 = X$, and $Z_n = Y$.

**Proof** (cf. [39, Theorem 1.9]). “If”: it is easy to see that any DG-comodule over $C$ is a union of its DG-subcomodules that are finitely generated bigraded $k$-modules. Let $X$ be such a DG-subcomodule in the DG-comodule $C$ over $C$. By the last assertion of Proposition B.2, there exists a distinguished triangle $Y \to X \to Z \to Y[1]$ in $D$ such that $H^n(Y) = 0$ for $n \leq 0$ and $H^n(Z) = 0$ for $n \geq 1$. Then the composition $Y \to X \to C$ vanishes as a morphism in $D$, since $\text{Hom}_{D(C\text{-comod})}(W, C) \simeq \text{Hom}_k(H^0(W_0), k)$ for any DG-comodule $W$ over $C$. On the other hand, the morphism $H^n(Y) \to H^n(X)$ is surjective for $n \geq 1$. Hence the morphism $H^n(X) \to H^n(C)$ vanishes for $n \geq 1$. Since this holds for all $X$, it follows that $H^n(C) = 0$. In fact, this argument does not depend on the assumption that the internal grading of $C$ is negative.

“Only if”: by Proposition B.6(b), it suffices to prove that the condition $(i')$ is satisfied. Let $D_{[−m,0]}$ denote the full triangulated subcategory of $D$ generated by the DG-comodules $k(i)$ with $−m \leq i \leq 0$ and $M_{[−m,0]} \subset D_{[−m,0]}$ be the minimal full subcategory, containing $k(i)$ and closed under extensions. We will show by induction on $m$ that $D_{[−m,0]} = \bigcup_{a,b} M_{[a,b]}^{[−m,0]}$. Since the homological dimension of $k$ is finite, it suffices to check that for any object $X \in D_{[−m,0]}$ there exists a distinguished triangle

$$Y' \to X' \to Z' \to Y'[1]$$

such that $Y$ belongs to the minimal full subcategory of $D_{[−m,0]}$ generated by $M_{[−m,0]}[−n]$ with $n > 0$ and closed under extensions, while $H^n(Z') = 0$ for $n > 0$.

Using the assumption that the internal grading of $C$ is negative, one can show by induction on the internal grading that any DG-comodule $M$ over $C$ is the filtered inductive limit of its DG-subcomodules $M'$ such that the map $H(M') \to H(M)$ is injective and the underlying $k$-module of $M'$ is finitely generated. In particular, we can assume that our DG-comodule $X$ is finitely generated as a bigraded $k$-module. Consider the complex of $k$-modules $X_0$; clearly, there exists a distinguished triangle $Y_0 \to X_0 \to Z_0 \to Y_0[1]$ in the derived category of $k$-modules such that $Y_0$ is a complex of finitely generated free $k$-modules concentrated in the cohomological degrees $n > 0$, while $H^n(Z_0) = 0$ for $n > 0$. Represent the object $Z_0$ by a finite complex of finitely generated $k$-modules such that the morphism $X_0 \to Z_0$ in the derived category comes from a morphism of complexes of $k$-modules.

Let $C_{≥−m}$ be the DG-subcomodule of the DG-comodule $C$ consisting of all components of the internal degree $i ≥ −m$. The morphism of complexes of $k$-modules $X \to Z_0$ induces a morphism of DG-comodules $X \to C_{≥−m} \otimes_k Z_0$. Let $W$ be a DG-subcomodule of $C_{≥−m} \otimes_k Z_0$ such that the map $H(W) \to H(C_{≥−m} \otimes_k Z_0)$ is...
Proposition C.2. Assume that 

(1) 

and closed under extensions, while 

By that theorem, the minimal full subcategory of

injective, the underlying \( k \)-module of \( W \) is finitely generated, \( W \) contains \( C_0 \otimes_k Z_0 \), and the morphism \( X \to C_{\geq -m} \otimes_k Z_0 \) factorizes through \( W \). Then, in particular, one has \( H^n(W) = 0 \) for \( n > 0 \). Let \( T[1] \) be the cone of the morphism \( X \to W \); then the component \( T_0 \) is isomorphic to the complex \( Y_0 \) in the derived category of \( k \)-modules. There is a distinguished triangle \( T_0 \to T \to T_{\leq -1} \to T_0[1] \) in the triangulated category \( D \).

By the assumption of induction on \( m \), there exists a distinguished triangle \( U \to T_{\leq -1} \to Y \to U[1] \) in \( D_{[-m,-1]} = D_{[-m+1,0]}(-1) \) such that \( U \) belongs to the minimal full subcategory of \( D_{[-m,-1]} \) generated by \( M_{[-m,-1]}[-n] \) with \( n > 0 \) and closed under extensions, while \( H^n(Y) = 0 \) for \( n > 0 \). It remains to use the \( \ast \)-associativity lemma in order to obtain the desired distinguished triangle \( Y \to X \to Z \to Y[1] \). \( \square \)

C.2. Negative cohomology. Assume that \( k \) is a field.

Proposition C.2. (1) \( M \) is the heart of a t-structure on \( D \) if and only if \( H^n(C) = 0 \) for \( n < 0 \).

(2) One has \( \text{Hom}_D(X, Y[n]) = 0 \) for all \( X, Y \in M \) and \( n < 0 \) provided that \( H^n(C) = 0 \) for \( n < -1 \).

Proof. One way to prove (1) is to use Theorem 1.1 for \( E_i = A(i) \in D \subset D(A\text{-mod}) \).

By that theorem, \( M \) is the heart of a t-structure if and only if \( H^n(A/A_0) = 0 \) for \( n \leq 0 \). It follows immediately from the forms of the reduced bar- and cobar-constructions and their mutual inverseness up to quasi-isomorphism that \( H^n(A/A_0) = 0 \) for \( n \leq 0 \) if and only if \( H^n(C/C_0) = 0 \) for \( n < 0 \).

This approach depends on the assumption of negative internal grading; the next one doesn’t. To prove “if”, replace \( C \) with its canonical truncation \( \tau^{\geq 0}C = C/(d(C^{-1}) + \sum_{n<0} C^n) \), which is quasi-isomorphic to \( C \); then the canonical truncations of DG-comodules over \( \tau^{\geq 0}C \) considered as complexes of \( k \)-vector spaces become also their canonical truncations as DG-comodules (cf. [39, Theorem 1.8(b)]).

To check “only if”, argue as in the proof of Theorem C.1, the “if” part, using the existence of a distinguished triangle \( Y \to X \to Z \to Y[1] \) in \( D \) such that \( H^n(Y) = 0 \) for \( n \geq 0 \) and \( H^n(Z) = 0 \) for \( n \leq -1 \).

Part (2) follows immediately from the form of the cobar-complex of \( C \). \( \square \)

Theorem C.3. (1) Assume that the bigraded \( k \)-algebra

\[ H(A) \cong \text{Hom}_{D(C\text{-comod})}(k, k(\ast)) \]

contains a central nonzero-dividing element \( t \) of internal degree \( -e \) and cohomological degree 0 such that the quotient algebra \( H(A)/\langle t \rangle \) modulo its zero internal degree component \( H(A_0) = k \) is concentrated in positive cohomological degrees. Then \( H^n(C) = 0 \) for \( n < -1 \).

(2) In the situation of (1), assume that \( e = 1 \) and the quotient algebra \( H(A)/\langle t \rangle \) is a Koszul algebra over \( k \) concentrated on the diagonal where sum of the cohomological and internal gradings is equal to zero. Let \( D \) denote the bar-construction of \( H(A)/\langle t \rangle \). Then the bigraded coalgebra \( H(C) \) is the tensor product of the internally graded coalgebra \( H(D) \), which is concentrated in
cohomological degree 0, and the exterior coalgebra $\Lambda(kt)$ with one cogenerator $t$ in the internal degree $-1$ and the cohomological degree $-1$.

(3) Assume that the DG-algebra $A$ contains an element $t$ of internal degree $-e$ and cohomological degree 0, annihilated by the differential, central in $A$, and nonzero-dividing in both $A$ and $H(A)$. Assume further that $H^n(A_i) = 0$ for all $n < 0$ and $0 > i > -e$. Let $D$ denote the bar-construction of the DG-algebra $B = A/(t)$. Then one has $H^n(D) = 0$ for all $n > 0$ if and only if $H^n(C) = 0$ for all $n > 0$, and $H^n(D) = 0$ for all $n < 0$ if and only if $H^n(C) = 0$ for all $n < -1$. If both of these conditions hold, the bigraded coalgebra $H(C)$ is the tensor product of the internally graded coalgebra $H(D)$ and the exterior coalgebra $\Lambda(kt)$ with one cogenerator $t$ in the internal degree $-e$ and the cohomological degree $-1$.

Proof. The silly filtration of the reduced bar-complex $\cdots \to A/A_0 \otimes_k A/A_0 \to A/A_0 \to k$ provides a spectral sequence starting from the cohomology of the bar-construction of $H(A)$ and converging to the cohomology of the bar-construction of $A$. This reduces part (1) to part (3), if one takes also into account (the first proof of) part (1) of the preceding proposition. To prove part (2), notice that in its assumptions the cohomology coalgebras of the bar-constructions of $A$ and $H(A)$ are isomorphic, since the grading on the cohomology of the bar-construction of $H(A)$ coming from the filtration coincides with the internal grading. So it remains to prove (3).

Consider the morphism of DG-algebras $f : A \to B$. Applying the left derived functor of extension of scalars $X \mapsto \mathbb{L}E_f(X) = B \otimes_A^L X$ [39, Section 1.7] to the trivial DG-module $k$ over the DG-algebra $A$, we obtain an object $\mathbb{L}E_f(k) \in D(B\text{-mod})$. Since the DG-module $B$ over $A$ is quasi-isomorphic to the cone of the morphism $A(-e) \to A$, the bigraded $k$-vector space $H(\mathbb{L}E_f(k))$ is two-dimensional, with one cohomology class in the internal grading 0 and cohomological grading 0, and another one in the internal grading $-e$ and cohomological grading $-1$. For the reasons of the natural filtration associated with the internal grading of DG-modules over $B$, there is a distinguished triangle

$$k(-e)[1] \to \mathbb{L}E_f(k) \to k \to k(-e)[2]$$

in $D(B\text{-mod})$. Applying the triangulated functor of DG-module bar-construction to this distinguished triangle, we obtain a distinguished triangle

$$D(-e)[1] \to C \to D \to D(-e)[2]$$

in $D(D\text{-comod})$ (for the computation of the (pre)image of the extension of scalars DG-module $\mathbb{L}E_f(k)$ under the bar-construction, see [39, Proposition 6.9]).

The vector space of morphisms $D \to D(-e)[2]$ in $D(D\text{-comod})$ is isomorphic to $H^{-2}(D_{-e})^*$; the linear function corresponding to a morphism is the induced map $H^{-2}(D_{-e}) \to H^0(D_0) = k$. For the morphism in the above distinguished triangle, this map is zero, since the map $H^0(D_0) \to H^{-1}(C_{-e})$ sends the unit element to the class of the element $t \in A/A_0[1] \subset C$. It suffices to check this in the case $A = k[t]$ and $B = k$, and then use the functoriality of our construction of distinguished triangle. It follows from the condition of vanishing of $H^n(A_i)$ for $n \leq 0$ and $0 > i > -e$ that this class in $H^{-1}(C_{-e})$ is nontrivial.
Thus there is a short exact sequence of left $H(D)$-comodules

$$0 \longrightarrow H(D(-e)[1]) \longrightarrow H(C) \longrightarrow H(D) \longrightarrow 0.$$ 

The “if and only if” assertions of part (3) follow immediately.

Now assume that $H^n(D) = 0$ for all $n \neq 0$. Define a decreasing filtration $F$ on the DG-algebra $A$ by the rule $F^p A = t^p A$. This filtration is finite on every internal degree component, so there is a spectral sequence starting from the cohomology of the bar-construction of $gr_F A$ and converging to the cohomology of the bar-construction of $A$. The associated graded DG-algebra $gr_F A$ is isomorphic to $B \otimes_k k[t]$, hence the cohomology of the bar-construction of $gr_F A$ is isomorphic to $H(D) \otimes_k \Lambda(kt)$. To check this, it suffices to construct the “shuffle product” morphism from the tensor product of bar-constructions to the bar-construction of the tensor product [34, Proposition 1.1 of Chapter 3], and then reduce the question to the case of DG-algebras with trivial multiplication and/or differential by passing to associated graded objects with respect to appropriate additional filtrations. The grading on the cohomology of the bar-construction of $gr_F A$ induced by the filtration $F$ coincides with minus the cohomological grading, hence the cohomology coalgebras of the bar-constructions of $A$ and $gr_F A$ are isomorphic. □

**Remark C.4.** In the situation of part (2) or (3) of Theorem C.3, one does not expect the DG-coalgebra $C$ to be quasi-isomorphic to its cohomology coalgebra $H(C)$, even though all the Massey comultiplications on $H(C)$ clearly vanish.

**Appendix D. Triangulated Categories of Morphisms**

The results of Section A.8 concerning the existence of (canonically defined and compatible with the composition) morphisms of functors $\theta^n_{\mathcal{E}, \mathcal{D}}$ for an exact subcategory $\mathcal{E}$ in a triangulated category $\mathcal{D}$ strongly suggest that there should exist a triangulated functor $\Theta : D^b(\mathcal{E}) \rightarrow \mathcal{D}$ compatible with the embeddings of $\mathcal{E}$ into $D^b(\mathcal{E})$ and $\mathcal{D}$. Unfortunately, it seems to be impossible to construct such a functor in general, because of the problems with nonfunctoriality of the cone in a triangulated category.

Here we will describe a refinement of the triangulated category structure that allows for construction of a functor $\Theta$. Two different versions of such a refinement were suggested in the papers [3], [32]; here we follow some kind of a middle path between the two. Namely, we use a modified form of the argument of [32] to show that the entire filtered triangulated category structure as defined in [3] is not needed for the above-mentioned purpose; it suffices to have the triangulated category of two-step filtrations, or, which is the same, the triangulated category of morphisms, or of distinguished triangles. Our goal is to prove that a functor $\Theta$ exists whenever the triangulated category $\mathcal{D}$ can be obtained from the homotopy category of (unbounded) complexes over some additive category by passing to triangulated subcategories and quotient categories any number of times.

**D.1. Filtered triangulated categories.** Let $[a, b] \subset \mathbb{Z}$ be a finite or infinite segment of the integers, $-\infty \leq a < b \leq +\infty$. An $[a, b]$-filtered triangulated category $(\mathcal{D}, F\mathcal{D})$ is the following set of data. A triangulated category $F\mathcal{D}$ is endowed with
a family of triangulated subcategories $\mathcal{DF}_i$, $i \in [a, b]$, such that $\mathcal{DF}$ is generated by $\mathcal{DF}_i$ and

$$\text{Hom}_{\mathcal{DF}}(X, Y) = 0 \quad \text{for all } X \in \mathcal{DF}_i, Y \in \mathcal{DF}_j, \text{and } i > j. \quad (D.1)$$

For a segment $[c, d] \subset [a, b]$, denote by $\mathcal{DF}_{[c, d]}$ the full triangulated subcategory of $\mathcal{DF}$ generated by $\mathcal{DF}_i$ with $i \in [c, d]$. A twist functor $X \mapsto X(1)$ acting from $\mathcal{DF}_{[a, b-1]}$ to $\mathcal{DF}_{[a+1, b]}$ is given such that $\mathcal{DF}_i+1 = \mathcal{DF}_i(1)$ for all $a \leq i \leq b - 1$. There is a natural transformation $\sigma_X: X \to X(1)$ for all $X \in \mathcal{DF}_{[a, b-1]}$ such that $\sigma_X(1) = \sigma_X(1)$ for all $X \in \mathcal{DF}_{[a, b-2]}$.

Finally, there is a functor $w: \mathcal{DF} \to \mathcal{D}$ such that $w(\sigma_X)$ is an isomorphism for all $X \in \mathcal{DF}_{[a, b-1]}$. The restriction of the functor $w$ to $\mathcal{DF}_i$ is an equivalence of categories $\mathcal{DF}_i \simeq \mathcal{D}_i$, and the map

$$w: \text{Hom}_{\mathcal{DF}}(X, Y) \longrightarrow \text{Hom}_{\mathcal{D}}(w(X), w(Y))$$

is an isomorphism for all $X \in \mathcal{DF}_{[a, i]}$ and $Y \in \mathcal{DF}_{[i, b]}$. \quad (D.2)

It follows from (D.1) that there is a triangulated functor of “successive quotients” $q = (q_i)_{i \in [a, b]}: \mathcal{DF} \to \prod_{\mathcal{DF}_i}$ (see [11, Sections 1 and 4] or [5, Lemma 1.3.2]).

**Example D.1.** Fix a segment $[a, b]$ as above. Let $\mathcal{E}$ be an exact category and $\mathcal{F}$ be the exact category of finitely filtered objects $Z$ in $\mathcal{E}$ as defined in Section A.5(5) for which $\text{gr}^i Z = 0$ for $i \notin [a, b]$. Set $\mathcal{D} = \mathcal{D}(\mathcal{E})$ and $\mathcal{DF} = \mathcal{DF}(\mathcal{F})$. Let $\mathcal{DF}_i \subset \mathcal{DF}$ be the image of the fully faithful triangulated functor $\mathcal{D} \to \mathcal{DF}$ induced by the embedding of exact categories $\mathcal{E} \to \mathcal{F}$ assigning to an object $X \in \mathcal{E}$ the filtered object $Z = X$ in $\mathcal{F}$ with $\text{gr}^i Z = X$ and $\text{gr}^i Z = 0$ for $j \neq i$. The block functor $Z \mapsto Z(1)$ is induced by the shift of the filtration, and the natural transformation $\sigma$ is defined in the obvious way. Finally, let $w: \mathcal{DF} \to \mathcal{D}$ be the triangulated functor induced by the forgetful functor $\mathcal{F} \to \mathcal{E}$ assigning to a finitely filtered object $Z \in \mathcal{F}$ the stabilizing limit of $\text{gr}^{i+j} X$ as $i \to -\infty$ and $j \to \infty$. The condition (D.1) is easy to check. As to the condition (D.2), it is obvious when the exact category structure on $\mathcal{E}$ is trivial, so $\mathcal{D} = \mathcal{K}(\mathcal{E})$ and $\mathcal{DF} = \mathcal{K}(\mathcal{F})$. The general case follows from the next proposition.

**Proposition D.2.** Let $(\mathcal{D}, \mathcal{DF})$ be an $[a, b]$-filtered triangulated category and $\mathcal{C} \subset \mathcal{D}$ be a triangulated subcategory. Denote by $\mathcal{CF} \subset \mathcal{DF}$ the triangulated subcategory consisting of all the objects $X \in \mathcal{DF}$ such that $w(q_i(X)) \in \mathcal{C}$ for all $i \in [a, b]$. Then

1. The pair $(\mathcal{C}, \mathcal{CF})$ with the additional data induced from that for the pair $(\mathcal{D}, \mathcal{DF})$ is an $[a, b]$-filtered triangulated category.

2. If $\mathcal{C} \subset \mathcal{D}$ is a thick subcategory, then so is $\mathcal{CF} \subset \mathcal{DF}$, and the pair $(\mathcal{D}/\mathcal{C}, \mathcal{DF}/\mathcal{CF})$ with the additional data induced from that for the pair $(\mathcal{D}, \mathcal{DF})$ is an $[a, b]$-filtered triangulated category.

**Proof.** Part (1) is obvious; let us prove part (2). Condition (D.1) and the equivalence $w: (\mathcal{DF}/\mathcal{CF}), \simeq \mathcal{D}/\mathcal{C}$ follow from [5, Section 1.3.3], so it remains to check (D.2).

Let us prove surjectivity. A morphism in the category $\mathcal{D}/\mathcal{C}$ is represented by a fraction $w(X) \leftarrow Q \to w(Y)$, where $A = \text{Cone}(Q \to w(X)) \in \mathcal{C}$. Let $\kappa_i: \mathcal{D} \simeq \mathcal{DF}_i \to \mathcal{DF}$ be the embedding inverse to the equivalence $w: \mathcal{DF}_i \to \mathcal{D}$. By the condition (D.2) for the pair $(\mathcal{D}, \mathcal{DF})$, there is a morphism $X \to \kappa_i(A)$ in $\mathcal{DF}$.
corresponding to the morphism \( w(X) \to A \) in \( \mathcal{D} \). Let \( T = \text{Cone}(X \to \kappa_i(A))[-1] \); since \( w\kappa_i(A) \simeq A \), we have \( w(T) \simeq Q \). Furthermore, \( T \in \mathcal{DF}_{\leq i} \), hence there is a morphism \( T \to Y \) corresponding to the morphism \( Q \to X \). The fraction \( X \leftarrow T \to Y \) provides the desired morphism \( X \to Y \) in \( \mathcal{DF}/\mathcal{CF} \).

To check injectivity, consider a fraction \( X \leftarrow T \to Y \) in \( \mathcal{DF} \) representing a morphism \( X \to Y \) in \( \mathcal{DF}/\mathcal{CF} \). First of all let us show that one can choose \( T \in \mathcal{DF}_{[a,i]} \). Let \( C = \text{Cone}(T \to X) \in \mathcal{CF} \); then there exists a distinguished triangle

\[
C_{\geq i+1} \to C \to C_{\leq i} \to C_{\geq i+1}[1], \quad C_{\geq i+1} \in \mathcal{DF}_{[i+1,b]}, \quad C_{\leq i} \in \mathcal{DF}_{[a,i]}.
\]

In fact, it will be only important for us that \( C_{\geq i+1} \in \mathcal{DF}_{[i,b]} \). It follows from (D.2) that the morphism \( C_{\leq i}[−1] \to C_{\geq i+1} \) decomposes as \( C_{\leq i}[−1] \to \kappa_i w(C_{\geq i+1}) \to C_{\geq i+1} \). Set \( C' = \text{Cone}(C_{\leq i}[−1] \to \kappa_i w(C_{\geq i+1})) \) and \( E = \text{Cone}(\kappa_i w(C_{\geq i+1}) \to C_{\geq i+1}) \). By (D.2), one has \( \text{Hom}_{\mathcal{DF}}(X, E[n]) = 0 \) for all \( n \). By the octahedron axiom, there is a distinguished triangle

\[
C' \to C \to E \to C'[1],
\]

hence the morphism \( X \to C \) factorizes through the morphism \( C' \to C \). Now let \( T' = \text{Cone}(X \to C')[-1] \); then the morphism \( T' \to X \) factorizes through the morphism \( T \to X \). By the construction, \( C' \in \mathcal{CF}_{[a,i]} \) and \( T' \in \mathcal{DF}_{[a,i]} \).

Finally, suppose that the morphism \( X \to Y \) in \( \mathcal{DF}/\mathcal{CF} \) represented by a fraction \( X \leftarrow T \to Y \) with \( T \in \mathcal{DF}_{[a,i]} \) maps to a zero morphism in \( \mathcal{D}/\mathcal{C} \). This means that the morphism \( w(T) \to w(Y) \) factorizes through an object \( A \in \mathcal{C} \). Then, by (D.2), the morphism \( T \to Y \) factorizes through the object \( \kappa_i(A) \in \mathcal{CF} \), hence our morphism \( X \to Y \) in \( \mathcal{DF}/\mathcal{CF} \) vanishes.

\[ \square \]

**Remark D.3.** It is also easy to see that if \( (\mathcal{D}, \mathcal{DF}) \) is an \([a, b]\)-filtered triangulated category, then so is \( (\mathcal{D}^\text{sat}, \mathcal{DF}^\text{sat}) \), where the triangulated category structure on the saturation of a triangulated category \([1]\) is presumed for \( \mathcal{D}^\text{sat} \) and \( \mathcal{DF}^\text{sat} \).

D.2. **Category of morphisms and realization functor.** From now on we will consider \([0, 1]\)-filtered triangulated categories, or triangulated categories of two-step filtrations. In this case, the twist functor \( Z \mapsto Z(1) \) and the natural transformation \( \sigma \) on \( \mathcal{DF} \) can be omitted in the definition of a filtered triangulated category, as they are determined by the remaining data.

Recall the notation \( \kappa_i, i = 0, 1 \), for the functors \( \mathcal{D} \simeq \mathcal{DF}_i \to \mathcal{DF} \) introduced in the proof of Proposition D.2. The condition (D.2) simply means that the functor \( w \) is right adjoint to \( \kappa_0 \) and left adjoint to \( \kappa_1 \). It follows from (D.1) that the functor \( w \circ q_0 \) is left adjoint to \( \kappa_0 \) and the functor \( w \circ q_1 \) is right adjoint to \( \kappa_1 \).

Finally, there is a functor \( \lambda: \mathcal{D} \to \mathcal{DF} \) left adjoint to the functor \( w \circ q_0 \). It is given by the rule \( \lambda(X) = \text{Cone}(\kappa_0(X) \to \kappa_1(X))[-1] \), where the morphism \( \kappa_0(X) \to \kappa_1(X) \) corresponds to the identity endomorphism of \( X \) under the isomorphism (D.2). The functor \( \lambda[1] \) is right adjoint to the functor \( w \circ q_1 \).

The situation has a triangular symmetry. Namely, setting \( \mathcal{DF}_0'' = \lambda(\mathcal{D}), \mathcal{DF}_1'' = \mathcal{DF}_0', \) and \( w'' = w \circ q_0 \) defines a new \([0, 1]\)-filtered triangulated category structure on the pair \( (\mathcal{D}, \mathcal{DF}) \), and the third such structure is given by \( \mathcal{DF}_0''' = \mathcal{DF}_1, \mathcal{DF}_1''' = \lambda(\mathcal{D}), \) and \( w''' = w \circ q_1 \). Ideally, one would like these three sets of data to be
permuted by a triangulated autoequivalence of $\mathcal{DF}$ whose third power would be isomorphic to the shift functor $Z \mapsto Z[1]$, but it is not clear how to obtain such an autoequivalence from our conditions (D.1–D.2).

**Theorem D.4.** Let $(\mathcal{D}, \mathcal{DF})$ be a $[0, 1]$-filtered triangulated category and $\mathcal{E}$ be an exact subcategory in $\mathcal{D}$ in the sense of Section A.8 such that $\text{Hom}_\mathcal{D}(X, Y[n]) = 0$ for all $X, Y \in \mathcal{E}$ and $n < 0$. Then there exists a natural triangulated functor $\Theta : \mathcal{D}^b(\mathcal{E}) \to \mathcal{D}$ whose restriction to $\mathcal{E}$ is the identity.

**Proof.** We start with constructing a functor from the category of bounded complexes $\text{Com}^b(\mathcal{E})$ over $\mathcal{E}$ (and closed morphisms between them) into $\mathcal{D}$. Let $\text{Com}^{[-n,0]}(\mathcal{E})$ denote the category of complexes concentrated in the interval $[c, d]$ of cohomological degrees. We proceed by induction in $n$ constructing a compatible system of functors $T_n : \text{Com}^{[-n,0]}(\mathcal{E}) \to \mathcal{D}$ such that $\text{Im} T_n \subset \mathcal{E}[n] \cdots \mathcal{E} \subset \mathcal{D}$ in the notation of [4, 1.3.9–10]. The embedding $E \to \mathcal{D}$ provides the functor $T_0$.

Given the functor $T_{n-1}$, we construct the functor $T_n$ as follows. Let $C^\bullet$ be a complex over $\mathcal{E}$ concentrated in the degrees $[-n, 0]$; then $C$ is the cone of a closed morphism of complexes $A^\bullet \to C^0$, where the complex $A^\bullet$ is concentrated in the degrees $[-n + 1, 0]$ and the object $C^0 \in \mathcal{E}$ is considered as a complex concentrated in degree 0. Consider the morphism $f_{C^\bullet} : \kappa_0(T_{n-1}(A^\bullet)) \to \kappa_1(C^0)$ in $\mathcal{DF}$ corresponding to the morphism $T_{n-1}(A^\bullet) \to C^0$ in $\mathcal{D}$. Since $\text{Hom}_\mathcal{D}(\mathcal{F}, \kappa_1(C^0), \kappa_0(T_{n-1}(A^\bullet))) = 0 = \text{Hom}_\mathcal{DF}(\kappa_0(T_{n-1}(A^\bullet)), \kappa_1(C^0)[−1])$, one can see that the cone of the morphism $f_{C^\bullet}$ is functorial in $C^\bullet$, i.e., defines a functor $\text{Com}^{[-n,0]}(\mathcal{E}) \to \mathcal{DF}$. Composing this functor with the functor $w$, we obtain the desired functor $T_n$.

It is clear that the functors $T_n$ agree with each other and are compatible with the cohomological shift, thus they extend to a functor $T : \text{Com}^b(\mathcal{E}) \to \mathcal{D}$. The functor $T$ is additive, since it preserves finite direct sums. A morphism $A^\bullet \to B^\bullet$ in $\text{Com}^b(\mathcal{E})$ is homotopic to zero if and only if it factorizes through the complex Cone(id$_{A^\bullet}$) or Cone(id$_{B^\bullet}$)[−1]), and this complex is isomorphic to the direct sum of the complexes Cone(id$_{A^\bullet}$). The latter complexes are clearly annihilated by $T$, hence the functor $T$ factorizes through the functor $\text{Com}^b(\mathcal{E}) \to \mathcal{K}^b(\mathcal{E})$. The thick subcategory $\mathcal{A}^b(\mathcal{E}) \subset \mathcal{K}^b(\mathcal{E})$ is generated by complexes of the form $0 \to X' \to X \to X'' \to 0$, where $X' \to X \to X''$ is an admissible triple in $\mathcal{E}$. One easily checks that such complexes are also annihilated by $T$, so $T$ factorizes through $\mathcal{D}^b(\mathcal{E})$.

We have constructed the functor $\Theta$; it remains to check that it preserves distinguished triangles. Any distinguished triangle in $\mathcal{D}^b(\mathcal{E})$ comes from a term-wise split short exact sequence of bounded complexes $C^\bullet \to D^\bullet \to E^\bullet$ over $\mathcal{E}$. One can assume that all the three complexes belong to $\text{Com}^{[-n,0]}(\mathcal{E})$. Present the complex $C^\bullet$ as the cone of a closed morphism $A^\bullet \to C^0$ and the complex $D^\bullet$ as the cone of a closed morphism $B^\bullet \to D^0$, where $A^\bullet, B^\bullet \in \text{Com}^{[-n+1, 0]}(\mathcal{E})$. To check that the image of our distinguished triangle in $\mathcal{D}^b(\mathcal{E})$ is a distinguished triangle in $\mathcal{D}$, it suffices to apply the 3×3-lemma [4, Proposition 1.1.11] to the commutative square formed by the morphisms $\kappa_0(T_{n-1}(A^\bullet)) \to \kappa_1(C^0) \to \kappa_1(D^0)$ and $\kappa_0(T_{n-1}(A^\bullet)) \to \kappa_0(T_{n-1}(B^\bullet)) \to \kappa_1(D^0)$ in $\mathcal{DF}$, together with the assumption of induction on $n$. \qed
Notice that one could also proceed in the dual way, cutting the leftmost term out of a complex \( C^* \), rather than the rightmost term, as we have done. This would provide another construction of a functor \( \Theta \). To prove that the two constructions produce isomorphic functors, one would probably need to assume the existence of a \([0, 2]\)-filtered triangulated category \( (\mathcal{D}, \mathcal{D}\tilde{F}) \) containing \( (\mathcal{D}, \mathcal{D}F) \).
