Session: 146. Enteric Infections and Diagnostics
Friday, October 6, 2017: 12:30 PM

Background. Little is known about the association between specific enteropathogens and disease severity in outpatient children with acute gastroenteritis. Recent advances in diagnostics enabling the rapid and simultaneous detection of common enteropathogens have become readily available. While such knowledge can be used to optimize therapy it also has the potential to predict disease severity. Such knowledge can aid clinical decision making, can clarify guidance and expectations provided to families, and can guide public health policy.

Methods. We conducted a prospective cohort study of children with acute gastroenteritis who were brought for emergency department care. The primary outcome measure was the 20-point Modified Vesikari Scale (MVS) score calculated from symptom onset until day14 of follow-up (total MVS score). Stool and/or rectal swab specimens were collected and analyzed for 18 unique pathogens by molecular diagnostic assays (in-house 5 virus panel, Luminex xTAG Gastrointestinal Pathogen Panel) and/or bacterial culture. An enteropathogen was deemed to be present if a candidate pathogen was identified in the rectal swab or stool specimen by any testing method. Binary logistic regression was performed to assess the association between pathogens (including all pathogens as present or not) and Peritonitis Reporting. The dependent variable being the total MVS score categorized as severe (11–20 points) vs. non-severe (0–10 points).

Results. The mean total MVS score (SD) was 12.8 (3.2) and 73.0% (807/1102) of participants experienced severe disease. A pathogen was identified in 72.8% (802/1102) of study participants. Rotavirus, norovirus GI and adenovirus were identified in 26.6% (293/1102), 23.0% (253/1102) and 16.0% (176/1102) of participants respectively. After adjusting for other pathogens significant predictors of severe disease were: rotavirus (OR=8.0; 95% CI: 4.8, 13.2), adenovirus (OR=2.1; 95% CI: 1.3, 2.2), Clostridium difficile (OR=1.6; 95% CI: 0.96, 2.6) and Aeromonas (OR=0.97; 95% CI: 0.2, 4.7) were significantly associated with severe disease.

Conclusions. In children with acute gastroenteritis, the enteropathogens associated with severe disease included rotavirus, Salmonella, adenovirus and norovirus GI.

1191. Comparison of Antibiotic Regimens in Intraabdominal Infections

Imran Hasanoglu, MD, PhD; Rahmet Guner, Prof. Dr.; Ruveyda Bilmez, MD; Bircan Kayaaslan, MD PhD.; Turgun Buzgun, Prof. Dr.; and Mehmet A. Tasyaran, Prof. Dr.; Infectious Diseases and Clinical Microbiology, Yildirim Beyazit University School of Medicine, Ankara, Turkey; Yildirim Beyazit University, School of Medicine, Ankara, Turkey, Yildirim Beyazit University, School of Medicine, Infectious Diseases and Clinical Microbiology, Ankara, Turkey.

Session: 146. Enteric Infections and Diagnostics
Friday, October 6, 2017: 12:30 PM

Background. Appropriate antimicrobial therapy and sometimes urgent surgery are life-saving in intra-abdominal infections (IAI).

Methods. We performed a retrospective case control study to evaluate the efficacy of ceftriaxone, ceftepime plus metronidazole, tigecycline, and ertapenem regimens in IAI. Patients aged >18 years and diagnosed with IAI between 2015 and 2017 were included in the study. Definitions are based on IDSA IAI guideline. Significant reductions of all signs and symptoms of IAI were seen with no further need for antimicrobial therapy or surgical intervention for infection is accepted as clinical response (CR). Microbiological response (MR) is assessed among patients with positive culture and defined as documented or presumptive microbiological eradication of pathogen.

Results. 659 patients are included in the study. Mean age was 56 years. Source control was maintained in 45.3% of patients. Among 54 patients with available culture specimen, E.coli was the most isolated pathogen (81.8% of all). Comparisons of antibiotics in all patients and in complicated IAI are shown in Table 1 and 2, respectively.

Conclusion. Ertapenem, and especially tigecycline are good options in IAI in the era of high antimicrobial resistance.

Disclosures. All authors: No reported disclosures.

1192. Microbiology of Infected Walled-off Necrosis Following Severe Acute Pancreatitis

Meridin Karan, MD; Nadav Sahar, MD; Richard Kozaerek, MD and Michael Gluck, MD; Internal Medicine, Section of Infectious Diseases, Virginia Mason Hospital and Seattle Medical Center, Seattle, Washington, Digestive Disease Institute, Virginia Mason Hospital and Seattle Medical Center, Seattle, Washington, Digestive Disease Institute, Virginia Mason Hospital and Seattle Medical Center, Seattle, Washington.

Session: 146. Enteric Infections and Diagnoses
Friday, October 6, 2017: 12:30 PM

Background. Formation of fluid collection occur in about 15–20% following severe acute pancreatitis. These fluid collections could become infected with bacterial and fungal organisms and form infected walled-off necrosis (WON). Management options for WON have evolved over the last decade from invasive surgical intervention to combined percutaneous and endoscopic approach (dual modality drainage (DMD)). We describe the culture result of WON obtained with DMD.

Methods. The study was performed at Virginia Mason Medical Center, a tertiary medical center located in Seattle. We used a prospective, institutional review board-approved database which include onset of pancreatitis, size of WON, timing of drainage, duration of treatment, culture result, antibiotics given, and in obese patients (P = 0.06). The longest diameter of WON nor sex of the patient did not significantly factor into whether the culture grew no organism, one organism, or multiple organisms.

Table 1. Comparison of antibiotic regimens in all patients (n, %, n±SD)
