ON ISOLATED SMOOTH CURVES OF LOW GENERA IN
CALABI-YAU COMPLETE INTERSECTION THREEFOLDS

ANDREAS LEOPOLD KNUTSEN

Abstract. Building on results of Clemens and Kley, we find criteria for a continuous family of curves in a nodal $K$-trivial threefold $Y_0$ to deform to a scheme of finitely many smooth isolated curves in a general deformation $Y_t$ of $Y_0$. As an application, we show the existence of smooth isolated curves of bounded genera and unbounded degrees in Calabi-Yau complete intersection threefolds.

1. Introduction

In this paper we study embeddings of complex projective curves into (smooth) Calabi-Yau complete intersection (CICY) threefolds. Such embeddings, and Calabi-Yau threefolds in general, have in the past decades been objects of extended interest in both algebraic geometry and physics. The goal of counting such curves (especially rational) has inspired the development of quantum cohomology and led to the discovery of surprising relations between algebraic geometry and the theory of mirror symmetry.

In the paper [7], Kley developed a framework for showing existence of curves of certain genera and degrees in CICY threefolds. The paper was built on the original idea in the case of genus zero curves of Clemens [1] (then it was also used in [6], [12] and [4]): one starts with a $K3$ complete intersection surface $X$ containing a smooth rational curve $C$, embeds the surface in a nodal CICY of suitable intersection type $Y$ and proves that under a general deformation $Y_t$ of $Y_0 = Y$, the rational curve deforms to an isolated curve in the deformation. In the higher genus case, the curve $C$ is replaced by a complete linear system $|L|$ of curves on the surface of dimension equal to the genus, and the idea is to prove that only finitely many of these deform to the deformation $Y_t$ and possibly also that these are smooth and isolated. The main existence result in [7] is [7, Thm. 1], claiming that for any $d \geq 3$, the general CICY threefold contains smooth, isolated elliptic curves of degree $d$, except for degree 3 curves in the CICY of type $(2,2,2,2)$.

A crucial point in this construction is to show that the curves on the $K3$ surface $X$ do not acquire any additional deformations when considered as curves in $Y$,
precisely that
\[ h^0(\mathcal{N}_{C/X}) = h^0(\mathcal{N}_{C/Y}) \text{ for all } C \in |\mathcal{L}|. \]

Unfortunately, the proof of this step, namely [7, Thm. 3.5], contains a serious gap, which also influences the proof of its corollary [7, Cor. 3.6], which in fact cannot hold (cf. Remark [6,6] for a more detailed explanation). As a consequence, the proof of [7. Thm. 1] is incorrect.

This paper has two main purposes:

• We give criteria for a continuous family of curves on a regular surface in a nodal threefold \( Y \) with trivial canonical bundle to deform to a scheme of finitely many smooth isolated curves in a general deformation \( Y_t \) of \( Y_0 = Y \), using results from [2] and ideas from the unpublished preprint [8] of Kley; see Theorem 1.1.
• We apply these results to prove existence of smooth, isolated curves of low genera in the various CICY threefold types; see Theorem 1.2 (of which [7, Thm. 1] is a special case).

The first main result is the following. It is an improvement under slightly stronger hypotheses of a result in the preprint [8] of Kley, which has never been published, presumably because of the gap in [7].

We first state the assumptions.

**Setting and assumptions.** Let \( P \) be a smooth projective variety of dimension \( r \geq 4 \) and \( \mathcal{E} \) a vector bundle of rank \( r-3 \) on \( P \) that splits as a direct sum of line bundles
\[ \mathcal{E} = \bigoplus_{i=1}^{r-3} \mathcal{M}_i. \]

Let
\[ s_0 = s_{0,1} \oplus \cdots \oplus s_{0,r-3} \in H^0(P, \mathcal{E}) = \bigoplus_{i=1}^{r-3} H^0(P, \mathcal{M}_i) \]
be a regular section, where \( s_{0,i} \in H^0(P, \mathcal{M}_i) \) for \( i = 1, \ldots, r-3 \). Set \( Y = Z(s_0) \) and \( Z = Z(s_{0,1} \oplus \cdots \oplus s_{0,r-4}) \) (where \( Z = P \) if \( r = 4 \)).

Let \( X \subset Y \) be a smooth, regular surface (i.e. \( H^1(X, \mathcal{O}_X) = 0 \)) and \( \mathcal{L} \) a line bundle on \( X \).

We make the following additional assumptions:

(A1) \( Y \) has trivial canonical bundle;

(A2) \( Z \) is smooth along \( X \) and the only singularities of \( Y \) which lie in \( X \) are \( \ell \) nodes \( \xi_1, \ldots, \xi_\ell \). Furthermore
\[ \ell \geq \dim |\mathcal{L}| + 2; \]

(A3) \( |\mathcal{L}| \neq \emptyset \) and the general element of \( |\mathcal{L}| \) is a smooth, irreducible curve;

(A4) for every \( \xi_i \in S := \{\xi_1, \ldots, \xi_\ell\} \), if \( |\mathcal{L} \otimes \mathcal{J}_{\xi_i}| \neq \emptyset \), then its general member is nonsingular at \( \xi_i \);

(A5) \( H^0(C, \mathcal{N}_{C/X}) \simeq H^0(C, \mathcal{N}_{C/Y}) \) for all \( C \in |\mathcal{L}| \);

(A6) \( H^1(C, \mathcal{N}_{C/P}) = 0 \) for all \( C \in |\mathcal{L}| \);
(A7) the image of the natural restriction map
\[ H^0(P, \mathcal{M}_{l-3}) \longrightarrow H^0(S, \mathcal{M}_{l-3} \otimes \mathcal{O}_S) \simeq \mathbb{C} \]
has codimension one.

Let \( s \in H^0(P, \mathcal{E}) \) be a general section. Then our result is the following:

**Theorem 1.1.** Under the above setting and assumptions (A1)-(A7), the members of \(|\mathcal{L}|\) deform to a length \( l + (|\mathcal{L}|) \) scheme of curves that are smooth and isolated in the general deformation \( Y_t = Z(s_0 + t s) \) of \( Y_0 = Y \). In particular, \( Y_t \) contains a smooth, isolated curve that is a deformation of a curve in \(|\mathcal{L}|\).

This result improves \[8\] Thm. 1.1, since the curves in that theorem are not claimed to be smooth or isolated.

Our main application is Theorem 1.2 below, of which \[7\] Thm. 1 is the special case with \( g = 1 \). Thus we give a correct proof of \[7\] Thm. 1 and, at the same time, extend the result to genera \( g > 1 \).

**Theorem 1.2.** Let \( d \geq 1 \) and \( g \geq 0 \) be integers. Then in any of the following cases the general Calabi-Yau complete intersection threefold \( Y \) of the given type contains an isolated, smooth curve of degree \( d \) and genus \( g \):

(a) \( Y = (5) \subset \mathbb{P}^4: g = 0 \) and \( d > 0 \); \( g = 1 \) and \( d \geq 3 \); \( 2 \leq g \leq 6 \) and \( d \geq g + 3 \); \( 7 \leq g \leq 9 \) and \( d \geq g + 2 \); \( g = 10 \) and \( d \geq 11 \); \( 11 \leq g \leq 22 \) and \( d \geq 2d+13 \).
(b) \( Y = (4, 2) \subset \mathbb{P}^5: g = 0 \) and \( d > 0 \); \( g = 1 \) and \( d \geq 3 \); \( g = 2 \) and \( d \geq 5 \);
\[ 3 \leq g \leq 8 \) and \( d \geq g + 4 \); \( 9 \leq g \leq 11 \) and \( d \geq g + 3 \); \( 12 \leq g \leq 15 \) and \( d \geq 2d+16 \).
(c) \( Y = (3, 3) \subset \mathbb{P}^5: g = 0 \) and \( d > 0 \); \( g = 1 \) and \( d \geq 3 \); \( g = 2 \) and \( d \geq 5 \);
\[ 3 \leq g \leq 7 \) and \( d \geq g + 4 \).
(d) \( Y = (3, 2, 2) \subset \mathbb{P}^6: g = 0 \) and \( d > 0 \); \( g = 1 \) and \( d \geq 3 \); \( g = 2 \) and \( d \geq 5 \);
\[ g = 3 \) and \( d \geq 7 \); \( 4 \leq g \leq 10 \) and \( d \geq g + 5 \).
(e) \( Y = (2, 2, 2) \subset \mathbb{P}^7: g = 0 \) and \( d > 0 \); \( g = 1 \) and \( d \geq 4 \); \( g = 2 \) and \( d \geq 6 \);
\[ g = 3 \) and \( d \geq 7 \).

We remark that the genus zero case of the theorem is already known by \[6\] \[12\] \[4\]. In \[8\] an existence result similar to Theorem 1.2 was claimed, but only for geometrically rigid, connected curves (not necessarily smooth and isolated). But the proof of that result also relied on \[7\] Thm. 3.5.

The paper is divided into two parts in a natural way: The first part, consisting of Sections 2-4, is devoted to the proof of Theorem 1.1. In Sections 2-4 we study deformations of curves in a complete linear system \(|\mathcal{L}|\) lying on a smooth surface \( X \) embedded in a nodal threefold \( Y \) with emphasis on the cases of regular surfaces in threefolds with trivial canonical bundle. Special attention is devoted to studying if the curves in \(|\mathcal{L}|\) on \( X \) acquire additional deformations when embedded in \( Y \), that is, to studying condition (A5). The crucial result is Proposition 4.3, which states that condition (A5) is equivalent to the condition (A5)′ The set of nodes \( S \) imposes independent conditions on \(|\mathcal{L}|\), and the natural map \( \gamma_C : H^0(C, \mathcal{N}_{X/Y} \otimes \mathcal{O}_C) \longrightarrow H^1(C, \mathcal{N}_{C/X}) \) (cf. (4.3)) is an isomorphism for all \( C \in |\mathcal{L}| \).

First of all, the conditions in (A5)′ may be easier to check than condition (A5) directly. More importantly, however, the first of the two conditions in (A5)′ assures
that the locus of curves in $|L|$ passing through at least one node is a simple normal crossing (SNC) divisor (consisting of $\ell$ hyperplanes). This enables us to identify a certain sheaf $Q$ of obstructions to deformation as the locally free sheaf of differentials with logarithmic poles along an SNC divisor; cf. (5.1), (5.2) and (5.3). This is a crucial point to assure that smooth and isolated curves survive in a general deformation $Y_t$ of $Y_0 = Y$.

The proof of Theorem 1.1 is finished in Section 5 following the proof of [8, Thm. 1.1].

In the second part, consisting of Sections 6 and 7, we apply Theorem 1.1 to the case of $K3$ surfaces in complete intersection Calabi-Yau threefolds to prove Theorem 1.2. For each of the complete intersection types in Theorem 1.2 there is a standard construction allowing one to embed a $K3$ surface of one (or more) of the three complete intersection types (4) in $\mathbb{P}^3$, (2, 3) in $\mathbb{P}^4$ and (2, 2, 2) in $\mathbb{P}^5$ into a nodal CICY threefold. This will be recalled in Section 6. We are then in the setting of Theorem 1.1 with $X$ the $K3$ surface, $Y$ the CICY, $P$ a projective space and $E$ the vector bundle corresponding to the complete intersection type of $Y$. All various complete intersection types and possible constructions are summarized in Table 1 in Section 6.

By construction and Bertini’s theorem, condition (A1) and the first part of condition (A2) are satisfied. In each of the cases in Theorem 1.2 we will then need to verify the remaining conditions (A2)-(A7), and this is the reason for the various numerical conditions on $d$ and $g$ in the theorem. To help the reader navigate through the proof, we now briefly explain how it works.

The existence of smooth curves of certain degrees and genera on the three types of complete intersection $K3$ surfaces is given by the existence results in [11] and [9]; cf. Theorem 7.1. We set $L$ to be the line bundle defined by the curves and an important point is that the existence results guarantee that $L$ and $O_X(1)$ are independent in Pic $X$.

Condition (A3) is automatically satisfied, as well as condition (A4), by standard arguments; cf. Lemma 6.1. Condition (A7) is also satisfied by construction; cf. Lemma 6.2. To check (A5) we will check the two conditions in (A5)$'$. We prove that the second one is satisfied in Proposition 6.5, and it is here that we need to use the fact that $L$ and $O_X(1)$ are independent in Pic $X$.

Therefore, at the end, the conditions that will be responsible for the numerical constraints in Theorem 1.2 are conditions (A2) and (A6), as well as the first condition in (A5)$'$, namely that the set of nodes $S$ imposes independent conditions on the linear system $|L|$. This is perhaps the most tricky condition to check, and we give sufficient conditions for this to hold in Lemma 6.3.

The numerical conditions we end up with are given in Proposition 7.2 (in addition to the conditions in the existence result Theorem 7.1). Finally, a case-by-case study of these conditions will give Theorem 1.2.

Conventions and definitions. The ground field is the field of complex numbers. We say a curve $C$ in a variety $V$ is geometrically rigid in $V$ if the space of embedded deformations of $C$ in $V$ is zero-dimensional. If furthermore this space is reduced, we say that $C$ is isolated or infinitesimally rigid in $V$. From the infinitesimal study of the Hilbert scheme of $V$, it follows that $C$ is infinitesimally rigid if and only if $H^0(C, N_{C/V}) = 0$. 
A K3 surface is a smooth projective (reduced and irreducible) surface $X$ with trivial canonical bundle and such that $H^1(O_X) = 0$. In particular $h^2(O_X) = 1$ and $\chi(O_X) = 2$.

A Calabi-Yau threefold $Y$ is a projective variety of dimension 3 with trivial canonical bundle and $h^1(O_Y) = h^2(O_Y) = 0$. In this paper a Calabi-Yau threefold will be at worst nodal.

2. Curves through nodes on threefolds, local theory

Let $Y = \{ (x, y, z, w) \in \mathbb{C}^4 \mid xw - yz = 0 \}$ be (the analytic germ of) a nodal threefold singularity in affine 4-space containing the plane $X = \{ (x, y, z, w) \in \mathbb{C}^4 \mid x = y = 0 \}$.

Let $J_{X/Y} \subset O_Y$ denote the ideal sheaf of $X$ in $Y$. A resolution of the $O_X$-module $J_{X/Y}$ is cyclic of the form

\[
\cdots O^\oplus 2_Y \xrightarrow{(\begin{smallmatrix} x \\ y \\ w \\ z \end{smallmatrix})} O^\oplus 2_Y \xrightarrow{(\begin{smallmatrix} w \\ -z \\ x \end{smallmatrix})} O^\oplus 2_X \xrightarrow{(x \quad y)} J_{X/Y} \longrightarrow 0
\]

so that we have

\[
\text{Ext}^i_{O_Y}(J_{X/Y}, O_X) = \begin{cases} 0, & \text{if } i \text{ is even}, \\ (z, w) \cong \mathbb{C}, & \text{if } i \text{ is odd}. \end{cases}
\]

Tensoring the sequence (2.1) with $O_X$ is terminally exact and so we obtain the resolution

\[
0 \longrightarrow O_X \xrightarrow{(w \quad -z)} O^\oplus 2_X \xrightarrow{(x \quad y)} \frac{J_{X/Y}}{J^2_{X/Y}} \longrightarrow 0
\]

of $\frac{J_{X/Y}}{J^2_{X/Y}}$ as an $O_X$-module. Thus

\[
N_{X/Y} := \text{Hom}_{O_X} \left( \frac{J_{X/Y}}{J^2_{X/Y}}, O_X \right) = \{(a, b) \in O^\oplus 2_X \mid wa = zb\} = \{(cz, cw) \mid c \in O_X\}
\]

is locally free. Moreover

\[
\text{Ext}^1_{O_X} \left( \frac{J_{X/Y}}{J^2_{X/Y}}, O_X \right) = \frac{O_X}{(z, w)} \cong \mathbb{C}.
\]

Now let $C = \{ (x, y, z, w) \in \mathbb{C}^4 \mid x = y = f(z, w) = 0 \}$ be a curve in $X$ passing through the node $(0, 0, 0, 0)$ of $Y$.

Tensoring (2.3) by $O_C$ we obtain the resolution

\[
0 \longrightarrow O_C \xrightarrow{(w \quad -z)} O^\oplus 2_C \xrightarrow{(y \quad f)} \frac{J_{X/Y}}{J^2_{X/Y}} \otimes O_C \longrightarrow 0
\]
of $\mathcal{O}_X \otimes \mathcal{O}_C$ as an $\mathcal{O}_C$-module, as the map $(w - z)$ is injective. Thus the map from (2.3) to (2.5) gives the commutative diagram

\[
\begin{array}{cccccc}
0 & \rightarrow & \mathcal{O}_X & \rightarrow & \mathcal{O}_X & \rightarrow & \mathcal{O}_C & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow  \\
0 & \rightarrow & \mathcal{O}_X^{\oplus 2} & \rightarrow & \mathcal{O}_X^{\oplus 2} & \rightarrow & \mathcal{O}_C^{\oplus 2} & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow  \\
0 & \rightarrow & \mathcal{J}_{X/Y}^{2} & \rightarrow & \mathcal{J}_{X/Y}^{2} & \rightarrow & \mathcal{J}_{X/Y}^{2} \otimes \mathcal{O}_C & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow  \\
0 & \rightarrow & 0 & \rightarrow & 0 & \rightarrow & 0 & \rightarrow & 0
\end{array}
\]

in which the first two columns are projective $\mathcal{O}_X$-resolutions of $\mathcal{J}_{X/Y}^{2}$ and the third is a projective $\mathcal{O}_C$-resolution of $\mathcal{J}_{X/Y}^{2} \otimes \mathcal{O}_C$.

For all $i \geq 0$, we define

\[
F_i^C := \mathcal{E}xt_i^{\mathcal{O}_X} \left( \mathcal{J}_{X/Y}^{2} \otimes \mathcal{O}_C, \mathcal{O}_C \right).
\]

Applying $\mathcal{H}om_{\mathcal{O}_X}(-, \mathcal{O}_X)$ to the first two columns of (2.6), we obtain

\[
\begin{array}{cccccc}
0 & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X, \mathcal{O}_X) & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X, \mathcal{O}_X) & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_C, \mathcal{O}_C) & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow  \\
0 & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X^{\oplus 2}, \mathcal{O}_X) & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X^{\oplus 2}, \mathcal{O}_X) & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_C^{\oplus 2}, \mathcal{O}_C) & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow  \\
0 & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{J}_{X/Y}^{2}, \mathcal{O}_X) & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{J}_{X/Y}^{2}, \mathcal{O}_X) & \rightarrow & F^0_C & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow  \\
0 & \rightarrow & 0 & \rightarrow & 0 & \rightarrow & 0 & \rightarrow & 0
\end{array}
\]

From the snake lemma we obtain the exact sequence

\[
\begin{array}{cccccc}
0 & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{J}_{X/Y}^{2}, \mathcal{O}_X) & \rightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{J}_{X/Y}^{2}, \mathcal{O}_X) & \rightarrow & F^0_C \\
\downarrow & & \downarrow & & \downarrow & & \downarrow  \\
\mathcal{E}xt_1^{\mathcal{O}_X}(\mathcal{J}_{X/Y}^{2}, \mathcal{O}_X) & \rightarrow & \mathcal{E}xt_1^{\mathcal{O}_X}(\mathcal{J}_{X/Y}^{2}, \mathcal{O}_X) & \rightarrow & F^1_C & \rightarrow & 0
\end{array}
\]

Since $f$ is the local equation of $C$, we can, by tensoring with $\mathcal{O}_C$, deduce the short exact sequence

\[
\begin{array}{cccccc}
0 & \rightarrow & \mathcal{N}_{X/Y} \otimes \mathcal{O}_C & \rightarrow & F^0_C & \rightarrow & \mathcal{E}xt_1^{\mathcal{O}_X}(\mathcal{J}_{X/Y}^{2}, \mathcal{O}_X) \otimes \mathcal{O}_C & \rightarrow & 0
\end{array}
\]
and the isomorphism
\begin{equation}
\label{eq:2.9}
\text{Ext}^1_{\mathcal{O}_X} \left( \frac{\mathcal{J}_{X/Y}}{\mathcal{J}_{X/Y}^2}, \mathcal{O}_X \right) \otimes \mathcal{O}_C \cong \mathcal{F}_C.
\end{equation}

3. Curves through nodes on threefolds, global theory

In this section \( X \) will be a smooth projective surface, \( Y \) a projective threefold and \( P \) a smooth projective variety of dimension \( \geq 4 \) such that \( X \subset Y \subset P \). We assume that the only singularities of \( Y \) lying on \( X \) are finitely many nodal singularities and that the embedding \( Y \subset P \) is regular (e.g., \( Y \) is a complete intersection in \( P \)). We denote the set of nodes of \( Y \) lying on \( X \) by \( S \).

Note that we have
\begin{equation}
\label{eq:3.1}
\text{Ext}^1_{\mathcal{O}_X} \left( \frac{\mathcal{J}_{X/Y}}{\mathcal{J}_{X/Y}^2}, \mathcal{O}_X \right) \cong \mathcal{O}_S,
\end{equation}
by (2.4).

Let \( L \) be a line bundle on \( X \) such that \(|L| \neq \emptyset \) and let \( C \in |L| \). We define the sheaves \( \mathcal{F}_C \) as in (2.7).

Applying \( \mathcal{H}om_{\mathcal{O}_C}(\mathcal{H}, \mathcal{O}_C) \) to
\begin{equation}
\label{eq:3.5}
0 \longrightarrow \mathcal{J}_{Y/P} \longrightarrow \mathcal{J}_{X/P} \longrightarrow \mathcal{J}_{X/P}^2 \longrightarrow 0
\end{equation}
we obtain the exact sequence
\begin{equation}
\label{eq:3.6}
0 \longrightarrow \mathcal{F}_0 \longrightarrow \mathcal{N}_{X/P} \otimes \mathcal{O}_C \longrightarrow \mathcal{N}_{Y/P} \otimes \mathcal{O}_C \longrightarrow \mathcal{F}_1 \longrightarrow 0
\end{equation}
and applying \( \mathcal{H}om_{\mathcal{O}_C}(\mathcal{H}, \mathcal{O}_C) \) to
\begin{equation}
\label{eq:3.7}
0 \longrightarrow \mathcal{F}_0 \longrightarrow \mathcal{N}_{C/P} \longrightarrow \mathcal{N}_{C/p} \otimes \mathcal{O}_C \longrightarrow \mathcal{F}_1 \longrightarrow 0
\end{equation}
we obtain the exact sequence
\begin{equation}
\label{eq:3.8}
0 \longrightarrow \mathcal{N}_{C/Y} \longrightarrow \mathcal{N}_{C/P} \longrightarrow \mathcal{N}_{Y/P} \otimes \mathcal{O}_C \longrightarrow \text{Ext}^1_{\mathcal{O}_C} \left( \frac{\mathcal{J}_{C/Y}}{\mathcal{J}_{C/Y}^2}, \mathcal{O}_C \right) \longrightarrow 0,
\end{equation}
because \( \text{Ext}^1_{\mathcal{O}_C} \left( \frac{\mathcal{J}_{C/P}}{\mathcal{J}_{C/P}^2}, \mathcal{O}_C \right) = 0 \), as \( C \subset P \) is a regular embedding.

Similarly, we also have the standard short exact sequence
\begin{equation}
\label{eq:3.9}
0 \longrightarrow \mathcal{N}_{C/X} \longrightarrow \mathcal{N}_{C/P} \longrightarrow \mathcal{N}_{X/P} \otimes \mathcal{O}_C \longrightarrow 0.
\end{equation}
Combining the sequences (3.3), (3.6), (3.8) and (3.9), together with the isomorphisms (3.1) and (3.4), we obtain

\[(3.10)\]

\[
\begin{array}{cccccccccccc}
0 & \downarrow & 0 & \downarrow & N_{C/X} & \downarrow & N_{C/X} & \downarrow & 0 & \downarrow & 0 & \downarrow & 0 & \downarrow & 0
\end{array}
\]

\[
\begin{array}{cccccccccccc}
0 & \rightarrow & N_{C/Y} & \rightarrow & N_{C/P} & \rightarrow & N_{Y/P} \otimes O_C & \rightarrow & \text{Ext}_1^1 O_C(J_{C/Y} J_{2C/Y}, O_C) & \rightarrow & 0
\end{array}
\]

\[
\begin{array}{cccccccccccc}
0 & \rightarrow & N_{X/Y} \otimes O_C & \rightarrow & N_{Y/P} \otimes O_C & \rightarrow & \mathcal{F}_C \simeq O_{S \cap C} & \rightarrow & 0 & \downarrow & 0 & \rightarrow & 0 & \rightarrow & 0
\end{array}
\]

4. Curves on regular surfaces in $K$-trivial threefolds with nodes

In this section we keep the hypotheses and notation from the previous section and assume further that

\[\omega_Y \simeq O_Y \text{ and } h^1(O_X) = 0.\]

By adjunction

\[(4.1)\] \[N_{X/Y} \simeq \omega_X\]

except at the finite set $S$. But both sides are locally free so the isomorphism holds everywhere. Therefore, again by adjunction,

\[(4.2)\] \[N_{X/Y} \otimes O_C \simeq \omega_C \otimes N_{C/X}^\vee,\]

so that (2.8) reads

\[(4.3)\] \[0 \rightarrow \omega_C \otimes N_{C/X}^\vee \rightarrow \mathcal{F}_C^0 \rightarrow O_{S \cap C} \rightarrow 0,\]

where we have used (3.1).

The main aim of this section is to find criteria for the curves $C \in |L|$ not to obtain any additional deformations in $Y$, that is, for the equality $h^0(N_{C/X}) = h^0(N_{C/Y})$ to hold for all $C \in |L|$.

We will need to consider, for $C \in |L|$, the composition

\[(4.4)\] \[\gamma_C : H^0(C, N_{X/Y} \otimes O_C) \rightarrow H^0(C, \mathcal{F}_C^0) \rightarrow H^1(C, N_{C/X}),\]

where the left hand inclusion $\iota_C$ arises from (2.8) (or, equivalently, (4.3)) and where the right hand map is the connecting homomorphism of (3.3). Note that $H^0(C, N_{X/Y} \otimes O_C)$ and $H^1(C, N_{C/X})$ are in fact dual by (4.2). Therefore, $\gamma_C$ is an isomorphism if and only if it is of maximal rank.

**Lemma 4.1.** Assume that $\omega_Y \simeq O_Y$ and $h^1(O_X) = 0$.

The inclusion $\iota_C$ is an isomorphism for all $C \in |L|$ if and only if $S$ imposes independent conditions on $|L|$.
Remark 4.2. The condition that \( S \) imposes independent conditions on \(|\mathcal{L}|\) means, precisely, that if \( \ell \) is the number of nodes, then \(|\mathcal{L} \otimes \mathcal{J}_S| = \emptyset \) if \( \ell > \dim |\mathcal{L}| \), and \( \dim |\mathcal{L} \otimes \mathcal{J}_S| = \dim |\mathcal{L}| - \ell \) if \( \ell \leq \dim |\mathcal{L}| \). This can also be rephrased as \( \dim |\mathcal{L} \otimes \mathcal{J}_{\xi_1} \otimes \mathcal{J}_{\xi_2} \otimes \cdots \otimes \mathcal{J}_{\xi_k}| = \dim |\mathcal{L}| - k \) for any subset \( \{\xi_1, \ldots, \xi_k\} \) of \( k \) nodes of \( S \), whenever \( k \leq \dim |\mathcal{L}| \), or, even simpler, that at most \( \dim |\mathcal{L}| \) of the nodes can lie on an element of \(|\mathcal{L}|\).

Note that if \( S \) imposes independent conditions on \(|\mathcal{L}|\), then, in particular, the points in \( S \) are different from the possible base points of \(|\mathcal{L}|\), so that the locus of curves in \(|\mathcal{L}|\) passing through at least one node is an effective divisor in \(|\mathcal{L}|\) consisting of hyperplanes. (If \( \dim |\mathcal{L}| = 0 \), this means that this locus is empty, that is, the only curve in \(|\mathcal{L}|\) does not pass through any of the points of \( S \).) Therefore the condition that the nodes impose independent conditions on \(|\mathcal{L}|\) can be rephrased as saying that the locus of curves in \(|\mathcal{L}|\) passing through at least one node is an effective, simple normal crossing (SNC) divisor consisting of hyperplanes.

Proof of Lemma \([11]\) By Serre duality we have that \( H^0(\mathcal{F}_C^0) \simeq Ext^1(\mathcal{F}_C^0, \omega_C)^\vee \). Applying \( \mathcal{H}om_{\mathcal{O}_C}(\cdot, \omega_C) \) to the bottom exact sequence of \((4.10)\), we find that \( Ext^1(\mathcal{F}_C^0, \omega_C) = 0 \), so that

\[
Ext^1(\mathcal{F}_C^0, \omega_C) \simeq H^1(\mathcal{H}om_{\mathcal{O}_C}(\mathcal{F}_C^0, \omega_C))
\]

by the local to global spectral sequence for \( \text{Ext} \). Moreover, applying \( \mathcal{H}om_{\mathcal{O}_C}(\cdot, \omega_C) \) to \((4.3)\), we obtain the short exact sequence

\[
(4.5) \quad 0 \longrightarrow \mathcal{H}om_{\mathcal{O}_C}(\mathcal{F}_C^0, \omega_C) \longrightarrow \mathcal{N}_{C/X} \longrightarrow \mathcal{O}_{S\cap C} \longrightarrow 0.
\]

Since \( h^1(\mathcal{O}_X) = 0 \), the restriction map \( H^0(\mathcal{L}) \longrightarrow H^0(\mathcal{N}_{C/X}) \) is surjective by

\[
(4.6) \quad 0 \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{L} \longrightarrow \mathcal{N}_{C/X} \longrightarrow 0.
\]

Hence

\[
\text{coker}\left\{ H^0(\mathcal{N}_{C/X}) \to H^0(\mathcal{O}_{S\cap C}) \right\} = \text{coker}\left\{ H^0(\mathcal{L}) \to H^0(\mathcal{O}_{S\cap C}) \right\}.
\]

Taking cohomology of \((4.5)\) we therefore obtain

\[
H^1(\mathcal{H}om_{\mathcal{O}_C}(\mathcal{F}_C^0, \omega_C)) \simeq \text{coker}\left\{ H^0(\mathcal{L}) \to H^0(\mathcal{O}_{S\cap C}) \right\} \oplus H^1(\mathcal{N}_{C/X}).
\]

It follows that

\[
H^0(\mathcal{F}_C^0) \simeq Ext^1(\mathcal{F}_C^0, \omega_C)^\vee \simeq H^1(\mathcal{H}om_{\mathcal{O}_C}(\mathcal{F}_C^0, \omega_C))^\vee \simeq \text{coker}\left\{ H^0(\mathcal{L}) \to H^0(\mathcal{O}_{S\cap C}) \right\} \oplus H^1(\mathcal{N}_{C/X})^\vee \simeq \text{coker}\left\{ H^0(\mathcal{L}) \to H^0(\mathcal{O}_{S\cap C}) \right\} \oplus H^0(\mathcal{N}_{X/Y} \otimes \mathcal{O}_C),
\]

by Serre duality and \((4.2)\) for the last isomorphism. Therefore, \( \iota_C \) is an isomorphism for all \( C \in |\mathcal{L}| \) if and only if

\[
H^0(\mathcal{L}) \longrightarrow H^0(\mathcal{O}_{S\cap C})
\]

is surjective for all \( C \in |\mathcal{L}| \), which precisely means that \( S \) imposes independent conditions on \(|\mathcal{L}|\). \( \square \)
The next result will be central in the rest of the paper.

**Proposition 4.3.** Assume that \( \omega_Y \simeq \mathcal{O}_Y \) and \( h^1(\mathcal{O}_X) = 0 \).

We have \( H^0(\mathcal{C}, \mathcal{N}_{C/X}) \simeq H^0(\mathcal{C}, \mathcal{N}_{C/Y}) \) for all \( C \in |\mathcal{L}| \) if and only if \( S \) imposes independent conditions on \( |\mathcal{L}| \) and the map \( \gamma_C \) in (4.4) is an isomorphism for all \( C \in |\mathcal{L}| \).

**Proof.** From the sequence (3.3) we have that \( H^0(\mathcal{N}_{C/X}) \simeq H^0(\mathcal{N}_{C/Y}) \) if and only if the connecting homomorphism \( H^0(F_C^0) \to H^1(\mathcal{N}_{C/X}) \) is injective. Since the spaces \( H^0(\mathcal{C}, \mathcal{N}_{X/Y} \otimes \mathcal{O}_C) \) and \( H^1(\mathcal{C}, \mathcal{N}_{C/X}) \) are dual by (4.2), this happens if and only if both the maps \( \iota_C \) and \( \gamma_C \) are isomorphisms. The result then follows from Lemma 4.1.

\[ \square \]

5. **Proof of Theorem 1.1**

In this section we prove Theorem 1.1. The result is a consequence of [2, Thms. 3.3 and 3.5] (and their proofs) and [7, Prop. 1.4 and Thm. 1.5], following the steps in the proof of [8, Thm. 1.1] almost verbatim except for an intermediate step where we apply Proposition 4.3 (cf. Remark 5.1 below) and exploit the fact that conditions (A3), (A4) and (A7) are stronger than the assumptions in [8, Thm. 1.1]. Since [8] has never been published, we give the whole proof of Theorem 1.1.

The setting and assumptions are as in the introduction. We observe the following:

**Remark 5.1.** By Proposition 4.3 condition (A5) is equivalent to the condition

(A5)' The set \( S = \{\xi_1, \ldots, \xi_\ell\} \) imposes independent conditions on \( |\mathcal{L}| \) and the map \( \gamma_C \) in (4.4) is an isomorphism for all \( C \in |\mathcal{L}| \).

**Proof of Theorem 1.1.** Since \( h^1(\mathcal{O}_X) = 0 \), we have that \( |\mathcal{L}| \simeq \mathbb{P}^\ell \) is a connected component of \( \text{Hilb} X \). By (A5) we have that \( |\mathcal{L}| \) is also a connected component of \( \text{Hilb} Y \), and by (A6) it has a smooth neighborhood \( \mathcal{H} \subset \text{Hilb} P \).

Let

\[
\begin{array}{ccc}
\mathcal{C}_0 & \xrightarrow{q_0} & Y \\
p_0 & \downarrow & \|
\mathcal{L} \\
& \downarrow & \\
\mathcal{L} & \xrightarrow{q} & \mathcal{P} \\
 & \downarrow & \\
 & \mathcal{H} & \\
\end{array}
\]

be the universal curves. Let \( \mathcal{I} \) be the ideal sheaf of \( \mathcal{C}_0 \) in \( |\mathcal{L}| \times Y \) and \( \mathcal{J} \) be the ideal sheaf of \( \mathcal{C}_0 \) in \( |\mathcal{L}| \times \mathcal{P} \).

Applying the functor

\[ F := p_{0*} \circ \text{Hom}_{\mathcal{C}_0}(-, \mathcal{O}_{\mathcal{C}_0}) \]

to the exact sequence

\[ 0 \to q_0^* \mathcal{E}^\vee \to \mathcal{J}/\mathcal{J}^2 \to \mathcal{J}/\mathcal{J}^2 \to 0 \]
of conormal sheaves and using the infinitesimal properties of Hilbert schemes gives
the exact sequence
\[ 0 \longrightarrow T_{|L|} \longrightarrow \mathcal{T} \otimes \mathcal{O}_{|L|} \longrightarrow p_0^*q_0^* \mathcal{E} \longrightarrow R^1F(3/3^2) \longrightarrow 0 \]
of \( \mathcal{O}_{|L|} \)-modules, as \( R^1F(3/3^2) = 0 \) by (A6).
Setting
\[ Q := R^1F(3/3^2) \]
we shorten the above to
\[ (5.1) \quad 0 \longrightarrow N_{|L|/\mathcal{H}} \longrightarrow p_0^*q_0^* \mathcal{E} \longrightarrow Q \longrightarrow 0. \]

By Remarks 4.2 and 5.1 condition (A5) implies that the locus of curves in \( |L| \simeq \mathbb{P}^{\dim |L|} \) passing through the node \( \xi_i \) is a hyperplane \( \mathcal{D}_i \subset |L| \) and, furthermore, that the locus of curves in \( |L| \) passing through at least one node, satisfies
\[ (5.2) \quad \mathcal{D} := \bigcup_{i=1}^\ell \mathcal{D}_i \text{ is simple normal crossing (SNC)}. \]

In fact, what we have done so far, is to go through the first part of the proof of [2, Thm. 3.3]. Since the notation in [2] is rather involved, we include the following translation between our notation and the notation in [2]:

| Our notation | Notation in [2] |
|--------------|-----------------|
| \( P \)      | \( P \)         |
| \( Y = Y_0 \) | \( X_0 \)       |
| \( |L| \)     | \( S' = S'(C) = I' \) |
| \( \mathcal{H} \) | \( J' \)       |
| \( C \)      | \( J \)         |
| \( C_0 \)    | \( S = I \)     |
| \( p, q \)   | \( p, q \)      |
| \( p_0, q_0 \) | \( pS, qS \)    |
| \( S \)      | \( \Xi \)       |
| \( \ell \)   | \( r(S) \)      |
| \( \xi_i \)  | \( x_i \)       |
| \( \mathcal{D}_i, \mathcal{D} \) | \( D_{S'}/D_{S'} \) |
| \( X \)      | \( Y_{S} \)     |
| \( \mathcal{Q} \) | \( Q_{S'} \)    |
| \( p_*q^* \mathcal{E} \) | \( V \) |

In particular, the conditions in [2, Thm. 3.3] are satisfied. Moreover, by (A4), the conditions in [2, Thm. 3.5] are also satisfied, so that
\[ (5.3) \quad Q \simeq \Omega^1_{|L|}[\log \mathcal{D}], \]
the locally free sheaf of differentials with logarithmic poles along an SNC divisor consisting of \( \ell \) hyperplanes (see e.g. [5], §2 for the definition).

By [7, Thm. 1.5] and (A6) we have that \( p_*q^* \mathcal{E} \) is locally free on \( \mathcal{H} \) and \( |L| \) is the zero scheme of \( p_*q^*s_0 \), so that [5,1] identifies \( Q \) as the excess normal bundle to \( p_*q^*s_0 \); cf. [2] §1.2. Again by [7, Thm. 1.5], the Hilbert scheme of the threefold \( Y_t := Z(s_0 + ts) \) satisfies
\[ \text{Hilb} Y_t \cap \mathcal{H} = Z(p_*q^*(s_0 + ts)). \]
This already finishes the proof in the case \( \dim |\mathcal{L}| = 0 \), by (A3). In the remaining cases it suffices to prove that \( \rho(p_{0,q_0} s) \) will vanish at precisely \( \binom{\ell - 2}{\dim |\mathcal{L}|} \) distinct points of \( |\mathcal{L}| \), all corresponding to smooth, irreducible curves in \( |\mathcal{L}| \). Indeed, by [11] Prop. 1.4 (and its proof), if \( \rho(p_{0,q_0} s) \) has a reduced and isolated zero at a point \( z \in |\mathcal{L}| \), then the scheme \( Z(p_{0,q_0}(s_0 + ts)) \) has a reduced and isolated zero in any small enough complex analytic neighborhood of \( z \) in \( \mathcal{H} \) for \( t > 0 \) sufficiently small. Since the curve corresponding to \( z \) is smooth, the same holds true in this neighborhood of \( z \). This will finish the proof of the theorem.

Assume then that \( \dim |\mathcal{L}| > 0 \). The fact that \( \ell \geq \dim |\mathcal{L}| + 2 \) in condition (A2) implies that the locally free sheaf \( \mathcal{Q} \cong \Omega^1_{\mathcal{L}^* \mathcal{L}} \) has globally generated (see e.g. [3] Thm. 3.5) for a proof of this fact) and that

\[
(5.4) \quad \int_{|\mathcal{L}|} c_{\text{top}}(\mathcal{Q}) = \left( \frac{\ell - 2}{\dim |\mathcal{L}|} \right) > 0.
\]

Consider the standard exact sequence

\[
0 \longrightarrow \Omega^1_{|\mathcal{L}|} \longrightarrow \mathcal{Q} \overset{\varepsilon = (\varepsilon_i)}{\longrightarrow} \bigoplus_{i=1}^{\ell} \mathcal{O}_{\mathcal{D}_i} \longrightarrow 0
\]

into which \( \mathcal{Q} \cong \Omega^1_{|\mathcal{L}|} \) sits (see e.g. [5] 2.3(a) or [3] Prop. 2.3), which is the same sequence as the one in [2] Thm. 3.3. By (A2) we can choose local coordinates in an analytic neighborhood of \( 0 = \xi_i \) in \( P \) such that

\[
s_0(x) = x_1 \oplus \cdots \oplus x_{r-4} \oplus \left( x_{r-3}^2 + \cdots + x_r^2 \right).
\]

Let \( s \in H^0(P, \mathcal{E}) = \bigoplus_{i=1}^{r-3} H^0(P, \mathcal{M}_i) \) and write

\[
s(x) = f_1(x) \oplus \cdots \oplus f_{r-3}(x)
\]

in the same coordinates. In the proof of [2] Thm. 3.3 it is shown that the composition

\[
H^0(P, \mathcal{E}) \longrightarrow H^0(|\mathcal{L}|, p_{0,q_0} \mathcal{E}) \overset{H^0(\rho)}{\longrightarrow} H^0(|\mathcal{L}|, \mathcal{Q}) \overset{H^0(\varepsilon)}{\longrightarrow} H^0(\mathcal{D}_i, \mathcal{O}_{\mathcal{D}_i})
\]

is given by

\[
s \longmapsto f_{r-3}(0).
\]

Therefore, the image of the composition

\[
H^0(P, \mathcal{E}) \longrightarrow H^0(|\mathcal{L}|, p_{0,q_0} \mathcal{E}) \overset{H^0(\rho)}{\longrightarrow} H^0(|\mathcal{L}|, \mathcal{Q}) \overset{H^0(\varepsilon)}{\longrightarrow} H^0(\mathcal{D}_i, \bigoplus_{i=1}^{\ell} \mathcal{O}_{\mathcal{D}_i})
\]

equals the image of the natural restriction map

\[
H^0(P, \mathcal{M}_{r-3}) \longrightarrow H^0(S, \mathcal{M}_{r-3} \otimes \mathcal{O}_S),
\]

which has codimension one by (A7). Since \( h^0(\mathcal{Q}) = \ell - 1 \), as is well known (see e.g. [3] Prop. 2.5), and \( h^0(|\mathcal{L}|, \Omega^1_{|\mathcal{L}|}) = 0 \), the map \( H^0(\varepsilon) \) is injective with image of codimension one. It follows that the composition morphism

\[
(5.5) \quad H^0(P, \mathcal{E}) \longrightarrow H^0(|\mathcal{L}|, p_{0,q_0} \mathcal{E}) \overset{H^0(\rho)}{\longrightarrow} H^0(|\mathcal{L}|, \mathcal{Q})
\]

is surjective. Thus, as \( \mathcal{Q} \) is globally generated, it follows by (5.4) that for the general section \( s \in H^0(P, \mathcal{E}) \), we have that \( \rho(p_{0,q_0} s) \) vanishes at precisely \( \binom{\ell - 2}{\dim |\mathcal{L}|} \) distinct
points of $|\mathcal{L}|$, all corresponding to smooth, irreducible curves in $|\mathcal{L}|$, by (A3), as desired. This finishes the proof of the theorem. □

**Remark 5.2.** Looking more closely at the proof, we see that the condition that $\mathcal{E}$ splits as a direct sum of line bundles is not necessary. It would suffice (when $r \geq 6$) that $\mathcal{E} = \mathcal{F} \oplus \mathcal{M}$, where $\mathcal{F}$ is a vector bundle of rank $r - 4$ and $\mathcal{M}$ is a line bundle on $P$. Writing $s_0 \in H^0(P, \mathcal{E})$ as $s_0 = s_{0,\mathcal{F}} \oplus s_{0,\mathcal{M}}$, with $s_{0,\mathcal{F}} \in H^0(P, \mathcal{F})$ and $s_{0,\mathcal{M}} \in H^0(P, \mathcal{M})$, we would then have $Z := Z(s_{0,\mathcal{F}})$ in the setting of Theorem 1.1.

6. **K3 surfaces embedded in nodal Calabi-Yau complete intersection threefolds**

The rest of the paper is devoted to proving Theorem 1.2.

We first recall the well-known construction used in [1], [6], [12] and [4] to embed a K3 surface into a nodal Calabi-Yau complete intersection (CICY) threefold.

It is well known, and easily seen by adjunction, that there are three types of (4) in $\mathbb{P}^4$, (2, 3) in $\mathbb{P}^5$ and (2, 2, 2) in $\mathbb{P}^6$. Similarly, there are five types of CICY threefolds in projective space, namely the intersection types (5) in $\mathbb{P}^4$, (3, 3) and (4, 2) in $\mathbb{P}^5$, (3, 2, 2) in $\mathbb{P}^6$ and (2, 2, 2, 2) in $\mathbb{P}^7$.

Let $X$ be a K3 surface of degree $2\mu - 2$ in $\mathbb{P}^\mu$ that is a complete intersection of type $(a_1, \ldots, a_r)$ in some $\mathbb{P}^r$, for $r \geq \mu$. We will always assume that

$$a_i \geq 2 \quad \text{for} \quad i \leq r - 4 \quad \text{and} \quad a_{r-3} \geq a_{r-2},$$

but we may have $a_{r-3} = 1$ or $a_{r-2} = 1$.

Let

$$b_i = a_i \quad \text{for} \quad i = 1, \ldots, r - 2, \quad \text{and} \quad b_{r-3} = a_{r-3} + a_{r-2}.$$

Then each $b_i \geq 2$ and we can construct a Calabi-Yau threefold $Y$ that is a complete intersection of type $(b_1, \ldots, b_{r-3})$ in $\mathbb{P}^r$ as follows: Choose generators $g_i$ of degrees $a_i$ for the ideal of $X$. So $X = Z(g_1, \ldots, g_{r-2})$. For general $\alpha_{ij} \in H^0(\mathbb{P}^r, \mathcal{O}_{\mathbb{P}^r}(b_i - a_j))$ define

$$f_i := \sum \alpha_{ij}g_j$$

and

$$Y := Z(f_1, \ldots, f_{r-3})$$

(here we follow [2] Section 3), except for arranging indices in a different way).

If the coefficient forms $\alpha_{ij}$ are chosen in a sufficiently general way, $Y$ has only $\ell = (2\mu - 2)a_{r-3}a_{r-2}$ ordinary double points and they all lie on $X$. This can be checked using Bertini’s theorem. In fact, the $\ell$ nodes are the intersection points of two general elements of $|\mathcal{O}_X(a_{r-3})|$ and $|\mathcal{O}_X(a_{r-2})|$ (distinct, when $a_{r-3} = a_{r-2}$).

As above, we denote the set of nodes by $S$.

Moreover, for general $\alpha_{ij}$, Bertini’s theorem yields that the fourfold

$$Z := Z(f_1, \ldots, f_{r-4})$$

is smooth. (Note that $Z = \mathbb{P}^r$ if $r = 4$.)

We are therefore in the setting of Theorem 1.1 given in the introduction with $P = \mathbb{P}^r$

$$E := \bigoplus_{i=1}^{r-3} \mathcal{O}_{\mathbb{P}^r}(b_i)$$
We can assume that \( L \) is a smooth, irreducible curve of degree \( d \) and genus \( g \). It is well known, and easily seen, that such a line bundle satisfies

\[
L^2 = 2g - 2, \quad h^0(L) = g + 1, \quad h^1(L) = h^2(L) = 0;
\]

see e.g. \cite{13}.

In the next section we will finish the proof of Theorem \ref{thm:main} by applying Theorem \ref{thm:existence} and a result guaranteeing the existence of the line bundle \( L \); cf. Theorem \ref{thm:existence}.

In particular, we will verify that conditions (A2)-(A7) are satisfied (under certain numerical conditions, giving the different constraints in Theorem \ref{thm:existence}). In the rest of this section we will give some results that will be needed for the verification of the conditions (A4), (A5) and (A7), where in the case of (A5) we will consider the equivalent condition (A5') from Remark \ref{rem:equivalent}.

The following result, which is folklore among experts on K3 surfaces, will be needed to verify that condition (A4) is satisfied.

**Lemma 6.1.** Let \( L \) be a line bundle on a K3 surface \( X \) such that \( |L| \) contains a smooth, irreducible curve. Assume that \( x \) is a point on \( X \) satisfying:

(i) \( x \) is not contained in any smooth rational curve \( \Gamma \) on \( X \) satisfying \( \Gamma \cdot L = 0 \);

(ii) if \( L^2 = 0 \), then \( x \) is not a singular point of any fiber of the elliptic pencil \( |L| \).

Then, the general element in \( |L \otimes J_x| \) (if nonempty) is nonsingular at \( x \).

**Proof.** We can assume that \( g = \dim |L| > 0 \). We then have that \( |L| \) is base point free (see \cite{13} Thm. 3.1) and \( \dim |L| = g \) and \( L^2 = 2g - 2 \geq 0 \) by \cite{12}.

If \( L^2 = 0 \) it is well known that \( |L| \) is an elliptic pencil (see \cite{13} Prop. 2.6) so that we are done by (ii). (Note that \( |L \otimes J_x| \) has only one element.)

If \( L^2 > 0 \) we consider the morphism \( \varphi_L : X \to \mathbb{P}^g \) and its Stein factorization

\[
X \xrightarrow{\alpha} X' \xrightarrow{\beta} \varphi_L(X).
\]

Then \( \alpha \) is the contraction of the finitely many smooth, rational curves \( \Gamma \) satisfying \( \Gamma \cdot L = 0 \) \cite{13} (4.2) and \( \beta \) is finite of degree one or two \cite{13} (4.1). It follows from

\[
\begin{array}{|c|c|c|c|c|c|c|}
\hline
(b_i) & (a_j) & \mu & \tau & \ell & \text{Sing} \ Y & a_{r-3} \ a_{r-2} \\
\hline
(5) & (4, 1) & 3 & 4 & 16 & X \cap Z(\alpha_{11}, \alpha_{12}) & 4 & 1 \\
(5) & (3, 2) & 3 & 4 & 36 & X \cap Z(\alpha_{11}, \alpha_{12}) & 3 & 2 \\
\hline
(4, 2) & (4, 1, 1) & 3 & 5 & 4 & X \cap Z(\alpha_{22}, \alpha_{23}) & 1 & 1 \\
(2, 4) & (2, 3, 1) & 4 & 5 & 18 & X \cap Z(\alpha_{11}, \alpha_{22023} - \alpha_{13022}) & 3 & 1 \\
(2, 4) & (2, 2, 2) & 5 & 5 & 32 & X \cap Z(\alpha_{21}, \alpha_{12} - \alpha_{22}, \alpha_{21}, \alpha_{13} - \alpha_{23}, \alpha_{11}) & 2 & 2 \\
(3, 3) & (3, 2, 1) & 4 & 5 & 12 & X \cap Z(\alpha_{21}, \alpha_{2011}, \alpha_{21}, \alpha_{13} - \alpha_{23}, \alpha_{11}) & 2 & 1 \\
(3, 2, 2) & (3, 2, 1, 1) & 4 & 6 & 6 & X \cap Z(\alpha_{22}, \alpha_{33} - \alpha_{23}, \alpha_{22}, \alpha_{22}, \alpha_{34} - \alpha_{24}, \alpha_{22}) & 1 & 1 \\
(2, 2, 3) & (2, 2, 1, 1) & 5 & 6 & 16 & X \cap Z(\text{linear, quadratic}) & 2 & 1 \\
(2, 2, 2) & (2, 2, 1, 1) & 5 & 7 & 8 & X \cap Z(\text{linear, quadratic}) & 1 & 1 \\
\hline
\end{array}
\]
Recall that hypothesis (i) that the base scheme of \(|L \otimes J_x|\) is finite of length at most two, whence is curvilinear. Therefore the general member of \(|L \otimes J_x|\) is smooth and irreducible by Bertini.

By this lemma, condition (A4) is satisfied for general \(\alpha_{ij}\). Indeed, the reduced and irreducible curves \(\Gamma\) on \(X\) satisfying \(\Gamma . L = 0\) are only finitely many by standard results, and the singular points of fibers in an elliptic pencil are also finitely many. Therefore, since the nodes are the points of intersection of two general (distinct) elements of \(|O_X (a_{r-3})|\) and \(|O_X (a_{r-2})|\), we can make sure that the nodes satisfy conditions (i) and (ii) in the lemma.

The next result shows that condition (A7) is satisfied.

**Lemma 6.2.** For general \(\alpha_{ij}\), the image of the natural restriction map

\[
H^0(P^r, O_{P^r}(a_{r-3} + a_{r-2})) \rightarrow H^0(S, O_S(a_{r-3} + a_{r-2})) \cong \mathbb{C}^\ell
\]

has codimension one.

**Proof.** Recall that \(S = H_1 \cap H_2\), for general members \(H_1 \in |O_X (a_{r-3})|\) and \(H_2 \in |O_X (a_{r-2})|\). We note that the map above factorizes through the natural restrictions to \(X\) and \(H_1\). The restriction map \(H^0(P^r, O_{P^r}(a_{r-3} + a_{r-2})) \rightarrow H^0(X, O_X (a_{r-3} + a_{r-2}))\) is surjective because \(X\) is a complete intersection. The restriction map \(H^0(X, O_X (a_{r-3} + a_{r-2})) \rightarrow H^0(H_1, O_{H_1}(a_{r-3} + a_{r-2}))\) is surjective from the cohomology of

\[
\begin{align*}
0 &\rightarrow O_X (a_{r-2}) \rightarrow O_X (a_{r-3} + a_{r-2}) \rightarrow O_{H_1}(a_{r-3} + a_{r-2}) \rightarrow 0, \\
\end{align*}
\]

as \(h^1(O_X (a_{r-2})) = 0\). Finally, the cokernel of the map \(H^0(H_1, O_{H_1}(a_{r-3}+a_{r-2})) \rightarrow H^0(S, O_S(a_{r-3} + a_{r-2}))\) is one-dimensional from the cohomology of

\[
\begin{align*}
0 &\rightarrow O_{H_1}(a_{r-3}) \rightarrow O_{H_1}(a_{r-3} + a_{r-2}) \rightarrow O_S(a_{r-3} + a_{r-2}) \rightarrow 0, \\
\end{align*}
\]

as \(O_{H_1}(a_{r-3}) \cong \omega_{H_1}\). This concludes the proof.

The following result gives criteria for the first of the two conditions in (A5)’ to hold:

**Lemma 6.3.** Assume that the \(\alpha_{ij}\) are general, that \(h^0(X, L \otimes O_X (-a_{r-2})) = 0\) and that

\[
a_{r-2}(2a_{r-3} - a_{r-2})(\mu - 1) \geq \begin{cases} \\
g + 2 & \text{if } a_{r-3} \neq a_{r-2}, \\
g + 1 & \text{if } a_{r-3} = a_{r-2}. \\
\end{cases}
\]

Then \(S\) imposes independent conditions on \(|L|\).

**Proof.** Fix any smooth, irreducible \(H_0 \in |O_X (a_{r-2})|\). Consider the incidence scheme

\[
W := \{ (\eta, \eta') \mid \eta' \subset \eta \} \subset \text{Sym}^{g+1}(H_0) \times |O_{H_0}(a_{r-3})|
\]

(note that \(\deg O_{H_0} (a_{r-3}) = \ell = 2a_{r-3}a_{r-2}(\mu - 1) \geq g + 1\) by our conditions). Let \(\pi_1 : W \rightarrow \text{Sym}^{g+1}(H_0)\) and \(\pi_2 : W \rightarrow |O_{H_0}(a_{r-3})|\) denote the projections. One easily computes that

\[
\dim |O_{H_0}(a_{r-3})| = \begin{cases} \\
ar_{r-2}(2a_{r-3} - a_{r-2})(\mu - 1) - 1 & \text{if } a_{r-3} \neq a_{r-2}, \\
ar_{r-2}a_{r-3}a_{r-2}a_{r-3}(\mu - 1) & \text{if } a_{r-3} = a_{r-2}, \\
\end{cases}
\]
so that \( \dim |O_{H_0}(a_{r-3})| \geq g+1 \) by our assumptions. It follows that \( \pi_1 \) is surjective. Since, for any \( \eta' \in \text{Sym}^{g+1}(H_0) \), we have \( \pi_1^{-1}(\eta') \simeq |O_{H_0}(a_{r-3}) \otimes \mathcal{J}_{\eta'}/H_0| \), it follows that \( W \) is irreducible.

For general \( \eta' \in \text{Sym}^{g+1}(H_0) \), we have}

\[
(6.3) \quad |\mathcal{L} \otimes \mathcal{J}_{\eta'}/X| = \emptyset.
\]

Indeed, for general \( x_1 \in H_0 \), we have \( \dim |\mathcal{L} \otimes \mathcal{J}_{x_1}/X| = \dim |\mathcal{L}| - 1 \), as \( H_0 \) cannot be a base component of \( |\mathcal{L}| \). Proceeding inductively, having picked general distinct \( x_1, \ldots, x_i \in H_0 \) for some \( i \in \{1, \ldots, g\} \) with \( \dim |\mathcal{L} \otimes \mathcal{J}_{x_1}/X \otimes \cdots \otimes \mathcal{J}_{x_i}/X| = \dim |\mathcal{L}| - i \geq 1 \), as \( \dim |\mathcal{L}| = g \), we have that the base locus of \( |\mathcal{L} \otimes \mathcal{J}_{x_1}/X \otimes \cdots \otimes \mathcal{J}_{x_i}/X| \) does not contain the whole of \( H_0 \), as \( h^0(\mathcal{L} - H_0) = h^0(\mathcal{L} \otimes \mathcal{O}_X(-a_{r-2})) = 0 \) by our assumption. Therefore, for any \( x_{i+1} \in H_0 \) outside of this base locus, we have that \( \dim |\mathcal{L} \otimes \mathcal{J}_{x_1}/X \otimes \cdots \otimes \mathcal{J}_{x_{i+1}}/X| = \dim |\mathcal{L}| - (i + 1) \) and we can continue, proving \( (6.3) \).

Now let

\[ W_{\mathcal{L}} := \left\{ (\eta', \eta) \in W \mid \dim |\mathcal{L} \otimes \mathcal{J}_{\eta'}/X| \neq \emptyset \right\} \subseteq W. \]

Since \( \pi_1 \) is surjective, we have \( W_{\mathcal{L}} \subseteq W \) by \( (6.3) \). Since \( \pi_2 \) is finite, we get that \( \pi_2(W_{\mathcal{L}}) \subseteq |O_{H_0}(a_{r-3})| \). Since \( h^1(\mathcal{O}_X(a_{r-3} - a_{r-2})) = 0 \), we conclude from the short exact sequence

\[
0 \longrightarrow \mathcal{O}_X(a_{r-3} - a_{r-2}) \longrightarrow \mathcal{O}_X(a_{r-3}) \longrightarrow \mathcal{O}_{H_0}(a_{r-3}) \longrightarrow 0,
\]

that for the general member \( H_1 \in |\mathcal{O}_X(a_{r-3})| \), the \( \ell \) distinct points \( H_1 \cap H_0 \) have the property that no \( g + 1 \) of them lie on any member of \( |\mathcal{L}| \). It follows that \( S \) imposes independent conditions on \( \mathcal{L} \); cf. Remark \( 4.2 \). \( \square \)

Finally, we will consider the second of the two conditions in \( (A5)' \).

We first recall the following result:

**Lemma 6.4** (\cite{7}, Lemma 1.10). Let \( X \subset \mathbb{P}^r \) be a smooth projective K3 surface with a line bundle \( \mathcal{L} \) such that \( \mathcal{L} \) and \( \mathcal{O}_X(1) \) are independent in \( \text{Pic} X \) and \( |\mathcal{L}| \) contains a smooth, irreducible curve. Then, for all \( C \in |\mathcal{L}| \), the composition

\[
\varphi : H^0(X, \mathcal{N}_{X/\mathbb{P}^r}) \longrightarrow H^0(X, \mathcal{N}_{X/\mathbb{P}^r} \otimes \mathcal{O}_C) \longrightarrow H^1(C, \mathcal{N}_{C/X})
\]

of the restriction with the connecting homomorphism arising from \( (3.9) \) with \( P = \mathbb{P}^r \) is surjective. Furthermore, \( \ker \varphi \) is independent of \( C \in |\mathcal{L}| \).

We now prove that, for general \( \alpha_{ij} \), the second of the two conditions in \( (A5)' \) from Remark \( 5.1 \) holds if \( \mathcal{L} \) and \( \mathcal{O}_X(1) \) are independent in \( \text{Pic} X \). The proof is taken basically verbatim from the last part of the proof of \cite{7}, Thm. 3.5) and we give it not only for the sake of completeness, but also because our statement is different and the proof of \cite{7}, Thm. 3.5] has a gap (cf. Remark \( 6.6 \) below).

**Proposition 6.5.** Suppose that the \( \alpha_{ij} \) are general and that the line bundles \( \mathcal{L} \) and \( \mathcal{O}_X(1) \) are independent in \( \text{Pic} X \). Then the map \( \gamma_C \) in \( (4.4) \) is an isomorphism for all \( C \in |\mathcal{L}| \).

**Proof** (follows the proof of \cite{7}, Thm. 3.5). We consider the commutative diagram

\[
(6.10)
\]

with \( P = \mathbb{P}^r \). By definition of \( \gamma_C \) and the fact that \( h^1(\mathcal{N}_{C/X}) = 1 \) for any \( C \in |\mathcal{L}| \) by \( (4.9) \) and \( (6.2) \), we just need to show that the connecting homomorphism
of the left hand vertical exact sequence in (3.10) is nonzero. A diagram chase in (3.10) reduces this to proving that for general \( \alpha_{ij} \) and all \( C \in |L| \), we have

\[
(6.4) \quad \delta_C(\ker H^0(\Phi_C)) \neq 0,
\]

where

\[
\delta_C : H^0(C, N_{X/Y} \otimes \mathcal{O}_C) \longrightarrow H^1(C, N_{C/X})
\]

is the connecting homomorphism of the right hand vertical exact sequence in (3.10) and \( \Phi_C \) is given in (3.10).

As in [7], we define \( \mathcal{A} := \bigoplus_{j=1}^{r-2} \mathcal{O}_{\mathbb{P}^r}(a_j) \) and denote by \( \mathcal{A}_X \) its restriction to \( X \).

Now we have natural isomorphisms

\[
(6.5) \quad N_{X/Y} \cong \mathcal{A}_X = \bigoplus_{j=1}^{r-2} \mathcal{O}_X(a_j) \quad \text{and} \quad \mathcal{N}_{Y/X} \otimes \mathcal{O}_X \cong \mathcal{E} \otimes \mathcal{O}_X \cong \bigoplus_{i=1}^{r-2} \mathcal{O}_X(b_i),
\]

under which the map

\[
\bigoplus_{j=1}^{r-2} H^0(\mathcal{O}_C(a_j)) \cong H^0(N_{X/Y} \otimes \mathcal{O}_C) \xrightarrow{H^0(\Phi_C)} H^0(N_{Y/X} \otimes \mathcal{O}_C) \cong \bigoplus_{i=1}^{r-2} H^0(\mathcal{O}_C(b_i))
\]

is given by the matrix \( (\pi_{ij}) \), where \( \pi_{ij} \) is the restriction of \( \alpha_{ij} \) to \( C \) (cf. [7] Lemma 3.4), where \( \mathcal{B} := \bigoplus_{i=1}^{r-3} \mathcal{O}_{\mathbb{P}^r}(b_i) = \mathcal{E} \).

To prove (6.4), use Gaussian elimination to find a generator \( N = N(\alpha_{ij}) \) of the null-space of the linear map \( \mathbb{C}^{r-2} \xrightarrow{(\alpha_{ij})} \mathbb{C}^{r-3} \). Keeping track of degrees, this can be done in such a way that the \( i \)th coordinate of \( N \) is of degree \( a_i \). For example, if \( (b_i) = (4,2) \) and \( (a_j) = (3,2,1) \), the vector \( N = (a_{12} \alpha_{23} - \alpha_{13} \alpha_{22}, -\alpha_{11} \alpha_{23}, \alpha_{111} \alpha_{22}) \). Since \( N \) is well-defined only up to scalar, we view it as a line in \( H^0(\mathbb{P}^r, \mathcal{A}) \) or a point of \( \mathbb{P}(H^0(\mathbb{P}^r, \mathcal{A})) \). Now each term of each coordinate of \( N \) is a term of a determinant of \( (\alpha_{ij}) \), so that as \( (\alpha_{ij}) \) varies, \( N \) hits a multiple of each element of the form \((0, \ldots, 0, \lambda_1 \lambda_2 \cdots \lambda_{a_i}, 0, \ldots, 0)\), where the \( \lambda_k \)s are of degree 1. Since the image of the Segre embedding of \( \mathbb{P}(H^0(\mathbb{P}^r, \mathcal{O}(1)))^X \alpha_{a_i} \) in \( \mathbb{P}(H^0(\mathbb{P}^r, \mathcal{O}(a_i))) \) is nondegenerate, the linear span of the image of \( N \) includes the spaces

\[
0 \oplus \cdots \oplus 0 \oplus H^0(\mathbb{P}^r, \mathcal{O}(a_i)) \oplus 0 \oplus \cdots \oplus 0
\]

and hence all of \( \bigoplus \mathbb{P} H^0(\mathbb{P}^r, \mathcal{O}(a_i)) \).

Now (6.4) follows from Lemma 6.2 since \( H^0(\mathbb{P}^r, \mathcal{A}) \to H^0(X, \mathcal{A}_X) \) is surjective for any complete intersection \( X \).

Remark 6.6. In [7] Thm. 3.5 it is claimed that \( H^0(N_{C/X}) \cong H^0(N_{C/Y}) \) for all \( C \in |L| \) under the same hypotheses as in Proposition 6.3. However, there is a mistake in the proof: it is claimed that there is a (not necessarily surjective) map \( \mu : N_{C/Y} \to N_{X/Y} \otimes \mathcal{O}_C \) fitting into the left bottom corner of (3.10). While this is true from (6.3) if \( C \cap S = \emptyset \), because then \( F^0_C = N_{X/Y} \otimes \mathcal{O}_C \) by (4.2) and (4.3), the same does not hold if \( C \) passes through some nodes of \( Y \). In this case, \( N_{X/Y} \otimes \mathcal{O}_C \) is a proper subsheaf of \( F^0_C \) and one cannot conclude that there is a map \( \mu \).

Moreover, the gap in the proof of [7] Thm. 3.5 also influences the proof of [7] Corollary 3.6, which in fact does not hold. Indeed, if \( H^0(N_{C/X}) \cong H^0(N_{C/Y}) \) for all \( C \in |L| \), then by (3.3), (4.3) and the fact that \( h^1(N_{C/X}) = h^1(\mathcal{O}_C(C)) = 1 \) for every \( C \in |L| \), we must have

\[
h^1(N_{C/Y}) = h^1(F^0_C) = g - \sharp(S \cap C).
\]
It therefore follows that [7, Corollary 3.6] does not hold for the curves $C \in |\mathcal{L}|$ passing through at least one of the nodes, as it is claimed there that $H^1(C, \mathcal{N}_{C/Y}) \simeq H^1(C, \mathcal{O}_C)$ for any $C \in |\mathcal{L}|$, and it is well known that $h^1(\mathcal{O}_C) = g$ for any $C \in |\mathcal{L}|$; cf. e.g. [7, Lemma 1.9(1)]. Unfortunately, [7, Corollary 3.6] is used in a crucial way in the proof of the main existence result [7, Thm. 1] (more precisely, it is used in the proof of [7, Prop. 3.9]).

**Remark 6.7.** It was noted by the referee of the original version of [11] that the same gap as in the proof of [7, Thm. 3.5] also appears in [2, Example 4.3]. It may be instructive to have a closer look at this as well and to see how Proposition 4.3 can be used to fill this gap and thus show that the conclusions in [2, Example 4.3] are correct. Clemens and Kley consider, with different notation, the two upper cases in Table 1, that is, either

\[(6.6) \quad g_1, \alpha_{12} \in H^0(\mathbb{P}^4, \mathcal{O}_{\mathbb{P}^4}(4)) \text{ and } g_2, \alpha_{11} \in H^0(\mathbb{P}^4, \mathcal{O}_{\mathbb{P}^4}(1))\]

or

\[(6.7) \quad g_1, \alpha_{12} \in H^0(\mathbb{P}^4, \mathcal{O}_{\mathbb{P}^4}(3)) \text{ and } g_2, \alpha_{11} \in H^0(\mathbb{P}^4, \mathcal{O}_{\mathbb{P}^4}(2))\]

(respectively cases (4.3.1) and (4.3.2) in their example), so that both the $K3$ surface $X := Z(g_1, g_2)$ (which they call $Y$) and the del Pezzo surface $X' := Z(g_2, \alpha_{11})$ (which they call $S$) are smooth, and such that the quintic threefold $Y := Z(\alpha_{11}g_1 + \alpha_{12}g_2)$ (which they call $X_0$) has only ordinary nodes (16 and 36 respectively), given by $S = Z(g_1, g_2, \alpha_{11}, \alpha_{12}) \subset X \cap X'$.

The authors claim that for any curve $C' \subset X'$, one has

\[(6.8) \quad H^0(\mathcal{N}_{C'/X'}) \simeq H^0(\mathcal{N}_{C/Y}).\]

To prove (6.8) they again state the existence of an exact sequence

\[0 \rightarrow H^0(C', \mathcal{N}_{C'/X'}) \rightarrow H^0(C', \mathcal{N}_{C/Y}) \rightarrow H^0(C', \mathcal{N}_{C/Y} \otimes \mathcal{O}_{C'}) \rightarrow 0.\]

As mentioned above, one cannot a priori conclude the existence of such a sequence. In fact, as we will see now, (6.8) does not hold in certain cases.

By Proposition 4.3 a necessary and sufficient condition for (6.8) to hold for all curves $C'$ in the linear system $|C'|$ is that the nodes $S$ impose independent conditions on $|C'|$, since $X'$ is a del Pezzo surface, so that $h^1(\mathcal{N}_{C'/X'}) = 0$ for all $C \in |C'|$ and $\gamma_{C'}$ is automatically surjective.

Now in case (6.6), let $C'$ be the quartic $X' \cap Z(g_1)$ on $X'$. Then $C'$ pass through all 16 nodes but $|\mathcal{O}_{X'}(C')| = |\mathcal{O}_{\mathbb{P}^2}(4)|$ is 14-dimensional. Hence the nodes $S$ do not impose independent conditions on $|C'|$, so that (6.8) does not hold for all curves in $|C'|$ in this case. In fact, it does not hold when one considers linear systems $|\mathcal{O}_{\mathbb{P}^2}(d)|$ with $d \geq 4$. This example also shows that the assertion “If the $g_i$ and the $\alpha_{ij}$ are sufficiently general, the divisor of curves passing through at least one node is a simple-normal crossing divisor consisting of hyperplanes” in [2, Example 4.3] does not hold if $d \geq 4$; cf. Remark 4.2.
We now show, however, that \( S \) does impose independent conditions on \(|O_{p2}(d)|\) when \( d \leq 3 \), using the same argument as in the proof of Lemma 6.3.

Remember that the 16 nodes of \( Y \) are the intersection points of two general elements of \(|O_{p2}(4)|\). Fix any smooth, irreducible \( H_0 \in |O_{p2}(4)| \) and consider the incidence scheme

\[
W := \left\{ (\eta', \eta) \mid \eta' \subset \eta \right\} \subset \text{Sym}^{\frac{1}{2}d(d+3)+1}(H_0) \times |O_{H_0}(4)|
\]

with projections \( \pi_1 \) and \( \pi_2 \) onto the first and second factor, respectively (recall that \( \dim |O_{p2}(d)| = \frac{1}{2}d(d + 3) \)). Since \( \dim |O_{H_0}(4)| = 14 \geq \frac{1}{2}d(d + 3) + 1 \) when \( d \leq 3 \), we have that \( \pi_1 \) is surjective. Since, for any \( \eta' \in \text{Sym}^{\frac{1}{2}d(d+3)+1}(H_0) \), we have \( \pi_1^{-1}(\eta') \simeq |O_{H_0}(4) \otimes \mathcal{J}_{\eta'/H_0}| \), it follows that \( W \) is irreducible. Now using the fact that \( |C' \otimes O_{p2}(-4)| = |O_{p2}(d-4)| = \emptyset \) as \( d \leq 3 \), one can easily prove that \( |O_{p2}(d) \otimes \mathcal{J}_{\eta'/X}| = \emptyset \) for general \( \eta' \in \text{Sym}^{\frac{1}{2}d(d+3)+1}(H_0) \), as in the proof of Lemma 6.3.

Now \( \pi_1 \) is surjective, so that letting

\[
W_C := \left\{ (\eta', \eta) \in W \mid \eta' \subset C' \text{ for some } C' \in |O_{p2}(4)| \right\} \subseteq W,
\]

we have that \( W_C \subseteq W \). Since \( \pi_2 \) is finite, we get that \( \pi_2(W_C) \subseteq |O_{H_0}(4)| \). Since \( H^0(O_{p2}(4)) \) surjects onto \( H^0(O_{H_0}(4)) \), we see that for the general member \( H_1 \in |O_{p2}(4)| \), the 16 distinct points \( H_1 \cap H_0 \) have the property that no \( \frac{1}{2}d(d + 3) + 1 \) of them lie on any member of \(|O_{H_0}(d)|\), for \( d \leq 3 \). Therefore, for general choices of \( g_1 \) and \( g_2 \), (6.3) is fulfilled for all curves \( C' \in |O_{p2}(d)| \) when \( d \leq 3 \).

The cases where \( d \leq 3 \) are in fact the cases where \( H^1(N_{C'/p^4}) = 0 \) for all \( C' \in |O_{p2}(d)| \), another condition needed to apply the results in [2], so that at the end, these are precisely the cases in [2] Example 4.3 where the authors compute the number of curves moving in a general deformation of the threefold. This shows that the conclusions in [2] Example 4.3 in case (6.7) are in fact correct.

In the same way one can show that the applications in case (6.7) are correct.

7. Proof of Theorem 1.2

In this section we apply Theorem 1.4 and the results from the previous section to construct smooth, isolated curves in general CICY's of each intersection type, thus proving Theorem 1.2.

Recall the following result from [11] and [9], which guarantees the existence of smooth curves of certain degrees and genera on the three types of complete intersection \( K3 \) surfaces:

**Theorem 7.1.** Let \( d > 0 \) and \( g \geq 0 \) be integers. Then:

(i) There exists a smooth quartic surface \( X \) in \( \mathbb{P}^3 \) containing a smooth, irreducible curve \( C \) of degree \( d \) and genus \( g \) such that \( \mathcal{O}_X(1) \) and \( \mathcal{O}_X(C) \) are independent in \( \text{Pic} X \) if and only if \( g < d^2/8 \) and \( (d, g) \neq (5, 3) \).

(ii) There exists a \( K3 \) surface \( X \) of type \((2, 3)\) in \( \mathbb{P}^4 \) containing a smooth, irreducible curve \( C \) of degree \( d \) and genus \( g \) such that \( \mathcal{O}_X(1) \) and \( \mathcal{O}_X(C) \) are independent in \( \text{Pic} X \) if and only if \( g = d^2/12 + 1/4 \) or \( g < d^2/12 \) and \( (d, g) \neq (7, 4) \).

(iii) There exists a \( K3 \) surface \( X \) of type \((2, 2, 2)\) in \( \mathbb{P}^5 \) containing a smooth, irreducible curve \( C \) of degree \( d \) and genus \( g \) such that \( \mathcal{O}_X(1) \) and \( \mathcal{O}_X(C) \) are independent in \( \text{Pic} X \) if and only if \( g = d^2/16 \) and \( d \equiv 4 \) (mod 8), or \( g < d^2/16 \) and \( (d, g) \neq (9, 5) \).
For $X$ and $C$ as in the theorem, we let $\mathcal{L} := \mathcal{O}_X(C)$.

In the setting described in the previous section, we now want to find out under which circumstances conditions (A1)-(A7) in Section 5 are satisfied, so that we can apply Theorem 1.1.

**Proposition 7.2.** Under the constraints given by Theorem 7.1, assume that the $\alpha_{ij}$ are general. If

$$d \leq 2a_{r-2}(\mu - 1) \text{ or } da_{r-2} > a_{r-2}^2(\mu - 1) + g$$

and

$$a_{r-2}(2a_{r-3} - a_{r-2})(\mu - 1) \geq \begin{cases} g + 2 & \text{if } a_{r-3} \neq a_{r-2}, \\ g + 1 & \text{if } a_{r-3} = a_{r-2}, \end{cases}$$

conditions (A1)-(A7) are satisfied.

**Proof.** Conditions (A1) and (A3) are obviously satisfied (as is the first part of (A2)). Condition (A4) is satisfied by Lemma 6.1 and the lines following the proof of that lemma. Condition (A7) is satisfied by Lemma 6.2.

The remaining three conditions (A2), (A5) and (A6) will be responsible for the numerical conditions (7.1) and (7.2).

Condition (A2) is satisfied whenever

$$\ell \geq g + 2,$$

since $\dim |\mathcal{L}| = g$ by (6.2), where $\ell = 2a_{r-3}a_{r-2}(\mu - 1)$ is the number of nodes of $Y$. We see that condition (7.2) implies condition (7.3).

We next consider condition (A6). Lemma 6.3 together with (3.9) and the fact that $\mathcal{N}_{X/P} \otimes \mathcal{O}_C = \bigoplus \mathcal{O}_C(a_j)$ by (5.3) yields

$$H^1(C, \mathcal{N}_{C/P}) \simeq H^1(C, \mathcal{N}_{X/P} \otimes \mathcal{O}_C) \simeq \bigoplus H^1(C, \mathcal{O}_C(a_j)).$$

Noting that $a_{r-2} = \min \{a_j\}$ by Table 1, we get in particular that $H^1(C, \mathcal{N}_{C/P}) = 0$ if and only if $h^1(C, \mathcal{O}_C(a_{r-2})) = 0$. By [9, Prop. 1.3] this is achievable for all $C \in |\mathcal{L}|$ if and only if

$$d \leq 2a_{r-2}(\mu - 1) \text{ or } da_{r-2} > a_{r-2}^2(\mu - 1) + g,$$

which is condition (7.1).

Therefore, (A6) is satisfied if and only if (7.1) holds.

Finally we consider condition (A5), or equivalently, by Remark 5.1 condition (A5)'.

By Proposition 6.5 and the fact that $\mathcal{L}$ and $\mathcal{O}_X(1)$ are independent in Pic $X$ by Theorem 7.1 the second of the two conditions in (A5)' is satisfied.

Next we note from the cohomology of

$$0 \longrightarrow \mathcal{L}^\vee \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{O}_C \longrightarrow 0$$

twisted by $\mathcal{O}_X(a_{r-2})$, Kodaira vanishing and Serre duality, that

$$h^0(X, \mathcal{L} \otimes \mathcal{O}_X(-a_{r-2})) = h^1(\mathcal{O}_C(a_{r-2})), $$

so that also $h^0(X, \mathcal{L} \otimes \mathcal{O}_X(-a_{r-2})) = 0$ if condition (7.1) holds, as we have just seen. Thus, by Lemma 6.3 the first of the two conditions in (A5)' is satisfied.
whenever (7.1) holds together with the condition
\[ a_{r-2}(2a_{r-3} - a_{r-2})(\mu - 1) \geq \begin{cases} 
  g + 2 & \text{if } a_{r-3} \neq a_{r-2}, \\
  g + 1 & \text{if } a_{r-3} = a_{r-2}, 
\end{cases} \]
which is condition (i).

To summarize, conditions (A1)-(A7) are satisfied for general \( \alpha_{ij} \) whenever (7.1) and (7.2) hold, subject to the constraints given by Theorem 7.1. □

Now to obtain Theorem 1.2 we just apply Theorem 1.1 taking into account the numerical conditions given in Theorem 7.1 and Proposition 7.2 for the various complete intersection types. Let us briefly explain how it works in case (a), that is, the case of \( Y \) a quintic threefold in \( \mathbb{P}^4 \). We then have \( r = 4 \) and \( (b_1) = (b_1) = 5 \).

Looking at Table 1, there are two choices for the \( K^3 \) surface \( X \), and the values of \( a_j, \mu, \ell \) are given in the two upper rows of the table. In particular, we have the two possibilities \( (a_1, a_2) = (4, 1) \) or \( (3, 2) \).

In the first case, \( (a_1, a_2) = (4, 1) \), we apply Theorem 7.1(i), where the numerical conditions are \( g < d^2/8 \) and \( (d, g) \neq (5, 3) \). Conditions (7.1) and (7.2) read
\[ d \leq 4 \text{ or } d \geq g + 3 \]
and
\[ g \leq 12. \]
Noting that we always have \( g < d^2/8 \) and \( (d, g) \neq (5, 3) \) when \( d \geq g + 3 \), all conditions put together yield
\[ 8g < d^2 \leq 16 \text{ or } g \leq \min\{12, d - 3\}. \] (7.4)

In the second case, \( (a_1, a_2) = (3, 2) \), we apply Theorem 7.1(ii), where the numerical conditions are \( g = (d^2 + 3)/12 \) or \( g < d^2/12 \) and \( (d, g) \neq (7, 4) \). Conditions (7.1) and (7.2) read
\[ d \leq 12 \text{ or } g \leq 2d - 13 \]
and
\[ g \leq 22. \]
Noting that we always have \( g < d^2/12 \) and \( (d, g) \neq (7, 4) \) when \( g \leq 2d - 13 \), and that the only integer values for \( d \) and \( g \) satisfying \( d \leq 12 \) and \( g = (d^2 + 3)/12 \) are \( (d, g) = (3, 1) \) and \( (9, 7) \), all conditions put together yield
\[ 12g < d^2 \leq 144 \text{ with } (d, g) \neq (7, 4), \]
or \( (d, g) \in \{(3, 1), (9, 7)\}, \text{ or } g \leq \min\{22, 2d - 13\}. \] (7.5)
Finding, for every \( g \), the lowest possible bound for \( d \) given by (7.4) and (7.5), yields the numerical conditions in Theorem 1.2(a).

Acknowledgements

The author thanks T. Johnsen, H. Clemens, H. P. Kley, A. F. Lopez, S. A. Stromme, S. Lekaus, R. Ile and G. Floystad for useful conversations on this subject.

The author was made aware of the gap in [7, Thm. 3.5] (and a similar one in [2, Example 4.3]; cf. Remark 6.7) by a referee of an earlier version of the preprint [10] from 2001, where the results of [7, 8] were applied to Calabi-Yau threefolds that are complete intersections in certain homogeneous spaces. (As a consequence, [10] has still not been published.) The author must therefore thank this referee for having...
discovered the gap in [7] and for a very carefully written referee report where he or she explained this in detail.

Finally, the author must thank the referee of this paper for a very careful reading of the manuscript and many suggestions. In particular, he or she caught a mistake in the first version and suggested a rewrite resulting in the present Sections 2-4 making the paper, the author believes, much clearer and easier to read.
