Carbon Footprint Study of Tesla Model 3

Gensheng Gui
GAC MOTOR CO., LTD. Guangzhou City, Guangdong, China

Abstract With the application of life cycle assessment method, according to the life cycle assessment standard, the Tesla Model 3 life cycle GHG emissions are accounted applying the CALCM and GREET in this paper obtaining the following conclusions: firstly, the GHG emissions value per unit distance of Tesla Model 3 is 376gCO₂/km, 17% higher than the average GHG emissions of B class ICEV in China, attributing mainly to the high power consumption during driving.

1 Overview
Energy saving and environmental protection are the two major themes for the world automobile development. Due to the high GHG emissions of the automobile industry, the resource consumption and environmental pollution caused by it cannot be ignored. At present, China's new energy vehicle industry achieves rapid development and strong growth in production and sales. In the trend of China's power cleanliness, the GHG emissions reduction of new energy vehicles has gradually become an advantage. However, the GHG emissions of different models of new energy vehicles vary greatly in the whole life cycle. The GHG emissions of certain models of new energy vehicles are even higher than traditional gasoline vehicles of the same class. As a result, the GHG emissions of new energy vehicles in their whole life cycle need to be further calculated.

Against this background, with the application of life cycle assessment method, according to the life cycle assessment standard such as ISO 14040[1], ISO 14044[2] and ISO 14067[3], GAC MOTOR CO., LTD. completed the accounting of life cycle GHG emissions of Tesla Model 3 based on real vehicle disassembly data, China Automotive Life Cycle Assessment Model (CALCM) and GREET.

2 Method

2.1 Goals and scope
Applying the LCA method, this study accounted the GHG emissions of the life cycle of Tesla Model 3, analyzed the contribution of each stage of the life cycle, so as to offer guidance for the automobile enterprises to use low-carbon materials, reduce the amount of materials, avoid the transfer of pollution, reduce energy consumption by applying low-carbon process technology, design and produce vehicles with lower GHG emissions.

2.1.1 Functional unit
In this report, the functional unit is the transportation service provided by Tesla Model 3 driving 1 km, and the life time driving distance is 150,000 km.

2.1.2 System boundary
Figure 1 shows that the Tesla Model 3 life cycle system boundary consists of the following stages: raw material acquisition, the production of the power battery and the automobile product, and the usage stage. In this study, the Tesla Model 3 is composed of various system components, power storage batteries, tires, lead-acid batteries, and liquid materials.
2.2 Life cycle list data

2.2.1 Data source

Each kind of raw materials (including steel, aluminum, copper and other metal materials and non-metallic materials such as plastics, glass and rubber for automobiles) in this report is represented by a typical vehicle raw material; the total mass of the vehicle’s main material covered in this study is 1860.3 kg. The Tesla Model 3 vehicle life cycle list data are derived from the disassembly. The background data for the raw material acquisition phase and power battery production comes from the GREET, and the background data for the use stage comes from CALCM, which is used to carry out the carbon emission calculation of passenger cars developed by Automotive Data Center, China Automotive Technology and Research Center Co., Ltd.

2.2.2 Raw material acquisition stage

This stage starts with the resources extraction from nature and ends with the application of raw materials in production facilities. The background data of steel, cast iron, aluminum alloy, magnesium alloy, plastic and other materials are derived from the GREET model; according to the disassembly of Tesla Model 3, the main system of automobiles and the list of materials for batteries, liquids, tires, etc. refer to Table 2.

Table 2 Component material input inventory

| Material    | Unit | Amount |
|-------------|------|--------|
| Steel       | kg   | 947.2  |
| Cast iron   | kg   | 3.5    |

Table 3 Material inventory of lead acid battery

| Material                  | Unit | Amount |
|---------------------------|------|--------|
| Plastic                   | kg   | 1.0    |
| Lead                      | kg   | 5.4    |
| Sulfuric acid             | kg   | 2.5    |
| Water                     | kg   | 2.6    |

Table 4 Material inventory of liquids

| Material                  | Unit | Amount |
|---------------------------|------|--------|
| Lubricants                | kg   | 2.3    |
| Brake Fluid               | kg   | 1.1    |
| Coolant/other glycols     | kg   | 13.1   |
| Refrigerant               | kg   | 1.5    |
| Washing water             | kg   | 1.3    |

Table 5 Material inventory of tires

| Material | Unit | Amount |
|----------|------|--------|
| Steel    | kg   | 6.2    |
| Rubber   | kg   | 40.1   |
2.2.3 Production stage

This stage starts with the automotive raw materials, components, and semi-finished products being applied in the production site, ends with the finished car being delivered from the production plant. For the automotive production stage, this study takes into account the energy consumption of the vehicle assembly process, which includes electrical energy, natural gas and CO₂ emissions used during stamping, welding, painting, final assembly. Moreover, the energy consumption of the Tesla Model 3 power battery production process has also considered in this study. The data for the production stage of Tesla Model 3 comes from the GREET model.

2.2.4 Use stage

The life time driving distance is set to be 150,000 km. The vehicle usage stage mainly includes energy consumption and material consumption. The electricity consumption of Tesla Model 3 is 26 kWh/100km. This study takes into account the difference between the actual driving process and the laboratory data and the electric energy loss during the charging process. The actual electricity consumption during the driving process is 35% higher than the laboratory data, referring to the survey of industry experts, while the actual electric energy loss during the charging process is set to be 12%, provided by the China Electric Vehicle Charging Infrastructure Promotion Alliance.

Furthermore, the replacement times of tires, batteries, liquids, etc. during the usage is set out in Table 6, and the data are derived from the survey of industry experts.

| Items          | Number of replacement |
|----------------|-----------------------|
| Tires          | Once 50,000 km        |

2.3 Impact assessment

This study applies GREET model to account Tesla Model 3 GHG emissions of the raw material acquisition stage and power battery production, and CALCM to calculate Tesla Model 3 GHG emissions of the usage stage.

3 Results

Using the research methods, based on the inventory analysis and impact assessment described in Chapter 2, the GHG emissions of Tesla Model 3 was obtained. The GHG emission of each stage of the life cycle are shown in Table 7.

| Life cycle stage                  | GHG emissions (gCO₂e/km) |
|----------------------------------|--------------------------|
| Raw material acquisition stage   | 62                       |
| Production stage                 | 10                       |
| Use stage                        | 304                      |
| Total                            | 376                      |

And figure 2 shows the proportion of GHG emissions in each stage of the life cycle. The GHG emissions per unit distance of Tesla Model 3 is mainly attributed to automobile usage stage, accounting for 81%, the raw material acquisition stage accounts for 16%.

![Figure 2](image-url)
Unlike most pure electric passenger cars, Tesla Model 3 not only has a GHG emissions higher than the average GHG emissions of same class ICEV in the raw material acquisition stage and production stage, but also has a GHG emissions value higher than the average GHG emissions of same class ICEV in the usage stage. This may be due to Tesla Model 3's power consumption is much higher than the average level of electric vehicles of the same class, resulting in a significant increase in GHG emissions during the use stage.
