Abstract—This paper considers the fundamental limit of compressed sensing for i.i.d. signal distributions and i.i.d. Gaussian measurement matrices. Its main contribution is a rigorous characterization of the asymptotic mutual information (MI) and minimum mean-square error (MMSE) in this setting. Under mild technical conditions, our results show that the limiting MI and MMSE are equal to the values predicted by the replica method from statistical physics. This resolves a well-known problem that has remained open for over a decade.

I. INTRODUCTION

The canonical compressed sensing problem can be formulated as follows. The signal is a random $n$-dimensional vector $X^n = (X_1, \ldots, X_n)$ whose entries are drawn independently from a common distribution $P_X$ with finite variance. The signal is observed using noisy linear measurements of the form

$$Y_k = \langle A_k, X^n \rangle + W_k,$$

where $\{A_k\}$ is a sequence of $n$-dimensional measurement vectors, $\{W_k\}$ is a sequence of standard Gaussian random variables, and $\langle \cdot, \cdot \rangle$ denotes the Euclidean inner product between vectors. The primary goal is to reconstruct $X^n$ from the set of $m$ measurements $\{(Y_k, A_k)\}_{k=1}^m$. Since the reconstruction problem is symmetric under simultaneous scaling of $X^n$ and $\{W_k\}$, the unit-variance assumption on $\{W_k\}$ incurs no loss of generality. In matrix form, the relationship between the signal and a set of $m$ measurements is given by

$$Y^m = A^m X^n + W^m,$$

where $A^m$ is an $m \times n$ measurement matrix whose $k$-th row is $A_k$.

This paper analyzes the minimum mean-square error (MMSE) reconstruction in the asymptotic setting where the number of measurements $m$ and the signal length $n$ increase to infinity. The focus is on scaling regimes in which the measurement ratio $\delta_n = m/n$ converges to a number $\delta \in (0, \infty)$. The objective is to show that the normalized mutual information (MI) and MMSE converge to limits,

$$\mathcal{I}_n(\delta_n) \triangleq \frac{1}{n} I(X^n; Y^n | A^m) \to \mathcal{I}(\delta)$$

$$\mathcal{M}_n(\delta_n) \triangleq \frac{1}{n} \text{mmse}(X^n | Y^m, A^n) \to \mathcal{M}(\delta),$$

almost everywhere and to characterize these limits in terms of the measurement ratio $\delta$ and the signal distribution $P_X$. We note that all mutual informations are computed in nats.

Using the replica method from statistical physics, Guo and Verdú [1] provide an elegant characterization of these limits in the setting of i.i.d. measurement matrices. Their result was stated originally as a generalization of Tanaka’s replica analysis of code-division multiple-access (CDMA) with binary signaling [2]. The replica method was also applied specifically to compressed sensing in [3]–[8]. The main issue, however, is that the replica method is not rigorous. It requires an exchange of limits that is unjustified, and it requires the assumption of replica symmetry, which is unproven in the context of the compressed sensing problem.

The main result of this paper is that replica prediction is correct for i.i.d. Gaussian measurement matrices provided that the signal distribution, $P_X$, has bounded fourth moment and satisfies a certain ‘single-crossing’ property. The proof differs from previous approaches in that we first establish some properties of the finite-length MMSE and MI sequences, and then use these properties to uniquely characterize their limits.

A. The Replica-Symmetric Prediction

We now describe the results predicted by the replica method. For a signal distribution $P_X$, the function $R: \mathbb{R}_+^2 \to \mathbb{R}_+$ is defined as

$$R(\delta, z) = I_X \left( \frac{\delta}{1+z} \right) + \frac{\delta}{2} \log(1+z) - \frac{z}{1+z},$$

where $I_X(s) = I(X; \sqrt{s}X + N)$ is the scalar mutual information function (in nats) of $X \sim P_X$ under independent Gaussian noise $N \sim \mathcal{N}(0, 1)$ with signal-to-noise ratio $s \in \mathbb{R}_+$ [1, 4].

**Definition 1.** The replica-MI function $\mathcal{I}_{RS}: \mathbb{R}_+ \to \mathbb{R}_+$ and the replica-MMSE function $\mathcal{M}_{RS}: \mathbb{R}_+ \to \mathbb{R}_+$ are defined as

$$\mathcal{I}_{RS}(\delta) = \min_{z \geq 0} R(\delta, z)$$

$$\mathcal{M}_{RS}(\delta) \in \arg \min_{z \geq 0} R(\delta, z).$$

The function $\mathcal{I}_{RS}(\delta)$ is increasing in $\delta$ and it is concave because it is the pointwise minimum of concave functions. The concavity implies that $\mathcal{I}'_{RS}(\delta)$ exists almost everywhere and is decreasing. It can also be shown that $\mathcal{M}_{RS}(\delta)$ is also decreasing and, thus, continuous almost everywhere. If the minimizer is not unique, then $\mathcal{M}_{RS}(\delta)$ may have jump discontinuities and may not be uniquely defined at those points; see Figure [1].
Assumption 1 (IID Gaussian Measurements). The rows of the measurement matrix \( \{ A_k \} \) are independent Gaussian vectors with mean zero and covariance \( n^{-1} I_n \). Furthermore, the noise \( \{ W_k \} \) is i.i.d. Gaussian with mean zero and variance one.

Assumption 2 (IID Signal Entries). The signal entries \( \{ X_i \} \) are independent copies of a random variable \( X \sim P_X \) with bounded fourth moment \( \mathbb{E}[X^4] \leq B \).

Assumption 3 (Single-Crossing Property). The signal distribution \( P_X \) satisfies the single-crossing property.

Theorem 1. Under Assumptions 1-3, we have

(i) The sequence of MI functions \( I_n(\delta) \) converges to the replica prediction. In other words, for all \( \delta \in \mathbb{R}_+ \),
\[
\lim_{n \to \infty} I_n(\delta) = I_{RS}(\delta).
\]

(ii) The sequence of MMSE functions \( M_n(\delta) \) converges almost everywhere to the replica prediction. In other words, for all continuity points of \( M_{RS}(\delta) \),
\[
\lim_{n \to \infty} M_n(\delta) = M_{RS}(\delta).
\]

Remark 1. The primary contribution of Theorem 1 is for the case where \( M_{RS}(\delta) \) has a discontinuity. This occurs, for example, in applications such as compressed sensing with sparse priors and CDMA with finite alphabet signaling. For the special case where \( M_{RS}(\delta) \) is continuous, the validity of the replica prediction can also be established by combining the AMP analysis with the 1-MMSE relationship [9]–[13].

Remark 2. For a given signal distribution \( P_X \) the single-crossing property can be verified by numerically evaluating the replica-MMSE and checking whether it crosses the fixed-point curve more than once.

C. Related Work

The replica method was developed originally to study mean-field approximations in spin glasses [14], [15]. It was first applied to linear estimation problems in the context of CDMA wireless communication [1], [2], [16], with subsequent work focusing on the compressed sensing directly [3]–[8].

Within the context of compressed sensing, the results of the replica method have been proven rigorously in a number of settings. One example is given by message passing on matrices with special structure, such as sparsity [9], [17], [18] or spatial coupling [19]–[21]. However, in the case of i.i.d. matrices, the results are limited to signal distributions with a unique fixed point [10], [12] (e.g., Gaussian inputs [22], [23]). For the special case of i.i.d. matrices with binary inputs, it has also been shown that the replica prediction provides an upper bound for the asymptotic mutual information [24]. Bounds on the locations of discontinuities in the MMSE with sparse priors have also been obtained by analyzing the problem of approximate support recovery [9]–[13].

Recent work by Huleihel and Merhav [25] addresses the validity of the replica MMSE directly in the case of Gaussian mixture models, using tools from statistical physics and random matrix theory [26], [27].

D. Notation

We use \( C \) to denote an absolute constant and \( C_\theta \) to denote a number that depends on a parameter \( \theta \). In all cases, the numbers \( C \) and \( C_\theta \) are positive and finite, although their values
change from place to place. The Euclidean norm is denoted by \( \| \cdot \| \). The positive part of a real number \( x \) is denoted by \( (x)_+ \triangleq \max(x, 0) \). The nonnegative real line \([0, \infty)\) is denoted by \( \mathbb{R}_+ \) and the positive integers \( \{1, 2, \cdots \} \) are denoted by \( \mathbb{N} \). For each \( n \in \mathbb{N} \) the set \( \{1, 2, \cdots, n\} \) is denoted by \([n]\).

The joint distribution of the random variables \( X, Y \) is denoted by \( P_{X,Y} \) and the marginal distributions are denoted by \( P_X \) and \( P_Y \). The conditional distribution of \( X \) given \( Y = y \) is denoted by \( P_{X|Y=y} \) and the conditional distribution of \( X \) corresponding to a random realization of \( Y \) is denoted by \( P_{X|Y} \). The expectation over a single random variable is denoted by \( \mathbb{E}_X \). For example, this implies that \( \mathbb{E}[f(X,Y)|Y] = \mathbb{E}_X[f(X,Y)] \).

Using this notation, the mutual information between \( X \) and \( Y \) can be expressed in terms of the expected Kullback-Leibler divergence as follows:

\[
I(X; Y) = D_{KL}(P_{X,Y} \| P_X \times P_Y) = \mathbb{E}[D_{KL}(P_{X|Y} \| P_X)] = \mathbb{E}[D_{KL}(P_{Y|X} \| P_Y)],
\]

where the expectation in the second line is with respect to \( Y \) and the expectation in the third line is with respect to \( X \).

The conditional variance of a random variable \( X \) given \( Y \) is denoted by

\[
\text{Var}(X|Y) = \mathbb{E}[(X - \mathbb{E}[X|Y])^2 | Y],
\]

and the conditional covariance matrix of a random vector \( X \) given \( Y \) is denoted by

\[
\text{Cov}(X|Y) = \mathbb{E}[(X - \mathbb{E}[X|Y])(X - \mathbb{E}[X|Y])^T | Y].
\]

The conditional variance and conditional covariance matrices are random because they are functions of the random conditional distribution \( P_{X|Y} \). The minimum mean-square error (MMSE) of \( X \) given \( Y \) is defined to be the expected squared difference between \( X \) and its conditional expectation and is denoted by

\[
\text{mmse}(X|Y) = \mathbb{E}[\|X - \mathbb{E}[X|Y]\|^2 | Y].
\]

Since the expectation is taken with respect to both \( X \) and \( Y \), the MMSE is a deterministic functions of the joint distribution \( P_{X,Y} \). The MMSE can also be expressed in terms of the expected trace of the conditional covariance matrix:

\[
\text{mmse}(X|Y) = \mathbb{E}[\text{tr}({\text{Cov}(X|Y)})].
\]

II. Overview of Main Steps in Proof

We begin with some additional definitions. The finite-length MI sequence \( I : \mathbb{N}^2 \to \mathbb{R}_+ \) and MMSE sequence \( M : \mathbb{N}^2 \to \mathbb{R}_+ \) are defined according to

\[
\begin{align*}
I_{m,n} & \triangleq I(X^n; Y^m | A^m), \\
M_{m,n} & \triangleq \frac{1}{n} \text{mmse}(X^n | Y^m, A^m),
\end{align*}
\]

where the relationship between the \( n \)-dimensional signal \( X^n \), \( m \)-dimensional measurements \( Y^m \), and \( m \times n \) measurement matrix \( A^m \) is given by the measurement model (1). Furthermore, the first and second order MI difference sequences are defined according to

\[
I'_{m,n} \triangleq I_{m+1,n} - I_{m,n},
\]

\[
I''_{m,n} \triangleq I'_{m+1,n} - I'_{m,n}.
\]

To simplify notation we will often drop the explicit dependence on the signal length \( n \) and simply write \( I_m, M_m, I'_m, \) and \( I''_m \).

A. Properties of Finite-Length Sequences

At its foundation, our proof relies on certain relationships between the MI and MMSE sequences. Observe that by the chain rule for mutual information,

\[
I(X^n; Y^m | A^m) = \sum_{k=1}^{m-1} I(X^n; Y_{k+1} | Y^k, A^{k+1}).
\]

Here, the conditioning in the mutual information on the right-hand side depends only on \( A^{k+1} \) because the measurement vectors are generated independently of the signal.

The above decomposition shows that the MI difference is given by \( I'_{m,n} = I(X^n; Y_{m+1} | Y^m, A^{m+1}) \). In other words, it is the mutual information between the signal and a new measurement \( Y_{m+1} \), conditioned on the previous data \( (Y^m, A^{m+1}) \). One of the key steps in our proof is to show that the MI difference and MMSE satisfy the following relationship almost everywhere

\[
I'_{m,n} \approx \frac{1}{2} \log(1 + M_{m,n}). \tag{2}
\]

Our approach relies on the fact that the gap between the right and left sides of (2) can be viewed as a measure of the non-Gaussianity of the conditional distribution of the new measurement. By relating this non-Gaussianity to certain properties of the posterior distribution, we are able to show that (2) is tight whenever the second order MI difference sequence is small. The details of these steps are given in Section IV.

Another important relationship that is used in our proof is the following fixed-point identity for the MMSE

\[
M_{m,n} \approx \text{mmse}_X\left(\frac{m/n}{1 + M_{m,n}}\right). \tag{3}
\]

In words, this says that the MMSE of the compressed sensing problem is approximately equal to that of a scalar problem whose signal-to-noise ratio is a function of the measurement rate. In Section V it is shown that the tightness in (3) can be bounded in terms of the tightness of (2).

B. Asymptotic Constraints

The previous subsection focused on relationships between the finite-length MI and MMSE sequences. To characterize these relationships in the asymptotic setting of interest, the finite-length sequences are extended to functions of a continuous parameter \( \delta \in \mathbb{R}_+ \) according to

\[
I'_n(\delta) = I'_{\lfloor \delta n \rfloor, n},
\]

\[
I_n(\delta) = \int_0^\delta I'_n(\gamma) \, d\gamma,
\]

\[
M_n(\delta) = M_{\lfloor \delta n \rfloor, n}.
\]

This choice of interpolation has the convenient property that the MI function \( I_n \) is continuous and differentiable almost
everywhere. Furthermore, by construction, $\mathcal{I}_n$ corresponds to
the normalized mutual information and satisfies $\mathcal{I}_n\left(\frac{m}{n}\right) = \frac{1}{n} I_{m,n}$ for all integers $m$ and $n$.

With this notation in hand, we are now ready to state two of the main theorems in this paper. These theorems provide precise bounds on the relationships given in (2) and (3). The proofs are given in Section IV and Section V.

**Theorem 2.** Under Assumptions 1 and 2, the MI and MMSE functions satisfy
\[
\int_0^\delta \left| I_n(\gamma) - \frac{1}{2} \log(1 + M_n(\gamma)) \right| d\gamma \leq C_{B,\delta} \cdot n^{-r},
\]
for all $n \in \mathbb{N}$ and $\delta \in \mathbb{R}_+$ where $r \in (0, 1)$ is a universal constant.

**Theorem 3.** Under Assumptions 1 and 2, the MMSE function satisfies
\[
\int_0^\delta \left| M_n(\gamma) - \text{mmse} \left( \frac{\gamma}{1 + M_n(\gamma)} \right) \right| d\gamma \leq C_{B,\delta} \cdot n^{-r},
\]
for all $n \in \mathbb{N}$ and $\delta \in \mathbb{R}_+$ where $r \in (0, 1)$ is a universal constant.

The bounds given in Theorems 2 and 3 are with respect to the signal-to-noise ratio, one can obtain the
relationship $\mathcal{I}_n(\delta) = \mathcal{I}_n(\delta, z)$ for all $\delta, z \in \mathbb{R}_+$. For fixed $n$ and $\delta$, let $V$ be the subset of non-increasing functions from $\mathbb{R}_+ \to \mathbb{R}_+$ such that all $g \in V$ satisfy the fixed-point condition
\[
g(\delta) = \text{mmse}_X \left( \frac{\delta}{1 + \mathcal{M}_{RS}(\delta)} \right),
\]
almost everywhere.

These properties show that the single-crossing property of the replica-MI to the replica-MMSE. Specifically, as a consequence of the envelope theorem and (4), it can be shown that the derivative of the replica-MI satisfies
\[
\mathcal{I}'_{RS}(\delta) = \frac{1}{2} \log(1 + \mathcal{M}_{RS}(\delta)),
\]
for all $\delta \in \mathbb{R}_+$, any minimizer $\mathcal{M}_{RS}(\delta)$ satisfies the fixed-point equation
\[
\mathcal{M}_{RS}(\delta) = \text{mmse}_X \left( \frac{\delta}{1 + \mathcal{M}_{RS}(\delta)} \right).
\]

C. **Uniqueness of Limit**

The final step of the proof is to make the connection between the asymptotic constraints on the MI and MMSE described in the previous subsection and the replica-MI and replica-MMSE functions given in Definition 1.

We begin by describing two functional properties of the replica limits. The first property follows from the fact that the MMSE is a global minimizer of the function $R(\delta, z)$ with respect to its second argument. Since $R(\delta, z)$ is differentiable for all $\delta, z \in \mathbb{R}_+$, any minimizer $\mathcal{M}_{RS}(\delta)$ must satisfy the equation $R_{\mathcal{M}_{RS}}(\delta) = 0$, where $R_{\mathcal{M}_{RS}}(\delta, z) = \frac{\partial}{\partial z} R(\delta, z)$. Using the I-MMSE relationship [28], it can be shown that, for each $\delta \in \mathbb{R}_+$, the replica-MMSE $\mathcal{M}_{RS}(\delta)$ satisfies the fixed-point equation
\[
\mathcal{M}_{RS}(\delta) = \text{mmse}_X \left( \frac{\delta}{1 + \mathcal{M}_{RS}(\delta)} \right).
\]

Note that if this fixed-point equation has a unique solution, then it provides an equivalent definition of the replica-MMSE. However, in the presence of multiple solutions, only the solutions that correspond to global minimizers of $R(\delta, z)$ are valid.

The second property relates the derivative of the replica-MI to the replica-MMSE. Specifically, as a consequence of the envelope theorem and (4), it can be shown that the derivative of the replica-MI satisfies
\[
\mathcal{I}'_{RS}(\delta) = \frac{1}{2} \log(1 + \mathcal{M}_{RS}(\delta)),
\]
for all $\delta \in \mathbb{R}_+$, any minimizer $\mathcal{M}_{RS}(\delta)$ satisfies the fixed-point equation
\[
\mathcal{M}_{RS}(\delta) = \text{mmse}_X \left( \frac{\delta}{1 + \mathcal{M}_{RS}(\delta)} \right).
\]

Furthermore, let $\mathcal{G} \subseteq V$ be the subset such that all $g \in \mathcal{G}$ also satisfy the large measurement rate boundary condition
\[
\lim_{\delta \to \infty} \int_0^\delta \frac{1}{2} \log(1 + g(\gamma)) d\gamma - \mathcal{I}_{RS}(\delta) = 0.
\]

In Section VI-A it is shown that if the signal distribution $P_X$ has the single-crossing property, then $\mathcal{M}_{RS}(\delta)$ has at most one discontinuity and all $g \in \mathcal{G}$ satisfy $g(\delta) = \mathcal{M}_{RS}(\delta)$ almost everywhere. In other words, the single-crossing property provides a sufficient condition under which the replica limits can be obtained uniquely from (5) and (6). A graphical illustration is provided in Figure 1.
III. PROPERTIES OF MI AND MMSE

A. Single-Letter Functions

The single-letter MI and MMSE functions corresponding to a real valued input distribution \( P_X \) under additive Gaussian noise are defined by

\[
I_X(s) = I(X; \sqrt{s}X + N)
\]

\[
\text{mmse}_X(s) = \text{mmse}(X | \sqrt{s}X + N),
\]

where \( X \sim P_X \) and \( N \sim \mathcal{N}(0,1) \) are independent and \( s \in \mathbb{R}_+ \) parametrizes the signal-to-noise ratio. Many properties of these functions have been studied in the literature \[28, 30 - 32\]. The function \( I_X(s) \) is concave and non-decreasing with \( I_X(0) = 0 \). If \( I_X(s) \) is finite for some \( s > 0 \) then it is finite for all \( s \in \mathbb{R}_+ \) \[32\] Theorem 6]. The MMSE function is non-increasing with \( \text{mmse}_X(0) = \text{Var}(X) \). Both \( I_X(s) \) and \( \text{mmse}_X(s) \) are infinitely differentiable on \((0, \infty)\) \[30\] Proposition 7].

The so-called I-MMSE relationship \[23\] states that

\[
\frac{d}{ds} I_X(s) = \frac{1}{2} \text{mmse}_X(s).
\] (7)

This relationship was originally stated for input distributions with finite second moments \[28\] Theorem 1], and was later shown to hold for any input distributions with finite mutual information \[32\] Theorem 6]. This relationship can also be viewed as a consequence of De-Bruijn’s identity \[33\].

Furthermore, it is well known that under a second moment constraint, the MI and MMSE are maximized when the input distribution is Gaussian. This yields the following inequalities

\[
I_X(s) \leq \frac{1}{2} \log(1 + s \text{Var}(X))
\] (8)

\[
\text{mmse}_X(s) \leq \frac{\text{Var}(X)}{1 + s \text{Var}(X)}.
\] (9)

More generally, the MMSE function satisfies the upper bound \( \text{mmse}_X(s) \leq 1/s \), for every input distribution \( P_X \) and \( s > 0 \) \[30\] Proposition 4]. Combining this inequality with (7) leads to

\[
I_X(t) - I_X(s) \leq \frac{1}{2} \log \left( \frac{t}{s} \right), \quad 0 < s \leq t,
\] (10)

which holds for any input distribution with finite mutual information.

Finally, the derivative of the MMSE with respect to \( s \) is given by the second moment of the conditional variance \[30\] Proposition 9],

\[
\frac{d}{ds} \text{mmse}_X(s) = -E[(\text{Var}(X | Y))^2].
\] (11)

This relationship shows that the slope of \( \text{mmse}_X(s) \) at \( s = 0 \) is finite if and only if \( X \) has bounded fourth moment. It also leads to the following result, which is proved in Appendix B-A

Lemma 5. The single-letter MMSE function satisfies the following bounds:

(i) For any input distribution \( P_X \) with finite fourth moment and \( s, t \in \mathbb{R}_+ \),

\[
|\text{mmse}_X(s) - \text{mmse}_X(t)| \leq 4E[X^4] |s - t|.
\] (12)

(ii) For every input distribution \( P_X \) and \( s, t \in (0, \infty) \),

\[
|\text{mmse}_X(s) - \text{mmse}_X(t)| \leq 12 \left| \frac{1}{s - t} \right|.
\] (13)

B. Multivariate MI and MMSE

From the chain rule for mutual information, we see that the MI difference sequence is given by

\[
I_{m,n} = I(X^n; Y_{m+1} | Y^m, A^{m+1}).
\] (14)

By the non-negativity of mutual information, this establishes that the MI sequence is non-decreasing in \( m \). Alternatively, by the data-processing inequality for MMSE \[34\] Proposition 4], we also see that \( M_{m,n} \) is non-increasing in \( m \), and also

\[
M_{m,n} \leq \text{Var}(X).
\]

The next result shows that the second order MI difference can also be expressed in terms of the mutual information. The proof is given in Appendix B-B

Lemma 6. Under Assumption 1, the second order MI difference sequence satisfies

\[
I_{m,n}'' = -I(Y_{m+1}; Y_{m+2} | Y^m, A^{m+2}).
\] (15)

One consequence of Lemma \[6\] is that the first order MI difference sequence is non-increasing in \( m \), and thus

\[
I_{m,n}' \leq I_{1,n}' = I_{1,n}.
\] (16)

This inequality plays an important role later on in our proof, when we show that certain terms of interest are bounded by the magnitude of the second order MI difference. The next result provides non-asymptotic bounds in terms of the single-letter MI and MMSE functions corresponding to the signal distribution \( P_X \). The proof is given in Appendix B-C

Lemma 7. Under Assumptions 1 and 2, the MI and MMSE sequences satisfy

\[
\sum_{k=1}^{\min(m,n)} E[I_X(\frac{1}{n} \chi_{m-k+1}^2)] \leq I_{m,n} \leq n E[I_X(\frac{1}{n} \chi_m^2)]
\] (17)

\[
E[\text{mmse}_X(\frac{1}{n} \chi_m^2)] \leq M_{m,n} \leq E[\text{mmse}_X(\frac{1}{n} \chi_{m-n+1}^2)],
\] (18)

where \( \chi_k^2 \) denotes a chi-squared random variable with \( k \) degrees of freedom and the upper bound on \( M_{m,n} \) is valid for all \( m \geq n \).

Remark 3. The proof of Lemma \[7\] does not require the assumption that the signal distribution has bounded fourth moment. In fact, (17) holds for any signal distribution with finite mutual information and (18) holds for any signal distribution.

Remark 4. The upper bound in (17) and lower bound in (18) are not new and are special cases of results given in \[8\].

Combining Lemma \[7\] with Inequalities (8) and (9), leads to upper bounds on the MI and MMSE that depend only on the variance of the signal distribution. Alternatively, combining Lemma \[7\] with the smoothness of the single-letter functions
given in (10) and (13) leads to the following characterization, which is tight whenever \( m \) is much larger than \( n \). The proof is given in Appendix B-D.

**Lemma 8.** Under Assumptions 1 and 2, the MI and MMSE sequences satisfy, for all \( m \geq n + 2 \),
\[
\frac{1}{2} |I_{m,n} - I_X \left( \frac{m}{n} \right)| \leq \frac{1}{2} \left[ \frac{n+1}{m-n-1} + \sqrt{\frac{2}{m-2}} \right] (19)
\]
\[
|M_{m,n} - \text{mmse}_X \left( \frac{m}{n} \right)| \leq \frac{12n}{m} \left[ \frac{n+1}{m-n-1} + \sqrt{\frac{2}{m-2}} \right]. (20)
\]

For any fixed \( n \), the right-hand sides of (19) and (20) converge to zero as \( m \) increases to infinity. Consequently, the large \( m \) behavior of the MI sequence is given by
\[
\lim_{m \to \infty} I_{m,n} = \left\{ \begin{array}{ll}
H(X^n), & \text{if } P_X \text{ has finite entropy} \\
+\infty, & \text{otherwise}.
\end{array} \right.
\]

**C. Properties of Replica Prediction**

Using the I-MMSE relationship, the partial derivative of \( R(\delta, z) \) with respect to its second argument is given by
\[
R_z(\delta, z) = \frac{\delta}{2(1+z)^2} \left[ z - \text{mmse}_X \left( \frac{\delta}{1+z} \right) \right]. (21)
\]

From this expression, we see that \( R_z(\delta, z) = 0 \) is equivalent to the fixed-point condition
\[
z = \text{mmse}_X \left( \frac{\delta}{1+z} \right).
\]

Furthermore, since \( I_{\text{RS}}(\delta) \) is concave, it is differentiable almost everywhere. For all \( \delta \) where \( I'_{\text{RS}}(\delta) \) exists, it follows from the envelope theorem \[29\] that \( I'_{\text{RS}}(\delta) = R_\delta(\delta, M_{\text{RS}}(\delta)) \), where \( R_\delta(z, \delta) \) is the partial derivative of \( R(\delta, z) \) with respect to its first argument. Direct computation yields
\[
R_\delta(z, \delta) = \frac{1}{2} \log(1+z) + \frac{1}{2(1+z)} \left[ \text{mmse}_X \left( \frac{\delta}{1+z} \right) - z \right].
\]

Finally, noting that the second term on the right-hand side is equal to zero whenever \( z = M_{\text{RS}}(\delta) \), leads to
\[
I'_{\text{RS}}(\delta) = \frac{1}{2} \log(1 + M_{\text{RS}}(\delta)).
\]

The proof of the next result is given in Appendix B-E.

**Lemma 9.** The Replica-MI and Replica-MMSE functions satisfy, for all \( \delta \geq 1 \),
\[
I_X(\delta - 1) \leq I_{\text{RS}}(\delta) \leq I_X(\delta), (22)
\]
\[
\text{mmse}_X(\delta) \leq M_{\text{RS}}(\delta) \leq \text{mmse}_X(\delta - 1). (23)
\]

It is interesting to note the parallels between the bounds on the MI and MMSE sequences in Lemma 7 and the bounds on the replica functions in Lemma 9. Combining Lemma 9 with the smoothness of the single-letter functions given in (10) and (13) leads to
\[
|M_{\text{RS}}(\delta) - \text{mmse}_X(\delta)| \leq \frac{1}{\delta(\delta - 1)}.
\]

**D. Proof of Theorem 4**

This proof follows from combining Lemmas 8 and 9. Fix any \( n \in \mathbb{R}_+ \) and \( \delta > 4 \) and let \( m = \lfloor \delta n \rfloor \) and \( \lambda = m + 1 - \delta n \). The MI function obeys the upper bound
\[
I_n(\delta) = \frac{1}{n} \left[ M_{m,n} + (1-\lambda)I_{m+1,n} \right]
\]
\[
\leq \frac{\lambda}{2} E[I_X \left( \frac{1}{n} \lambda \right)^2] + (1-\lambda)E[I_X \left( \frac{1}{n} \lambda_{m+1} \right)] (a)
\]
\[
\leq I_X(\delta), (24)
\]
where: (a) follows from [17]; and (b) follows from Jensen’s inequality and the concavity of \( I_X(s) \). The MI function also obeys the lower bound
\[
I_n(\delta) \geq \frac{1}{n} I_{m,n}
\]
\[
\geq I_X(\delta) - \frac{1}{2(\delta-1)} - \frac{1}{2} \left[ \frac{n+1}{(\delta-1)n-2} - \sqrt{\frac{2}{\delta-3}} \right], (25)
\]
where (a) follows from the fact that \( I_{m,n} \) is non-decreasing in \( m \) and (b) follows from [19], [10], and the fact that \( m \geq \delta n - 1 \geq \delta - 1 \). Finally, we have
\[
I_n(\delta) - I_{\text{RS}}(\delta) \leq \frac{\lambda}{2} E[I_X \left( \frac{1}{n} \lambda \right)^2] + (1-\lambda)E[I_X \left( \frac{1}{n} \lambda_{m+1} \right)]
\]
\[
\leq \frac{(\delta-1)^2}{2(\delta-1)n-2} + \frac{1}{2} \sqrt{\frac{2}{\delta-3}},
\]
where: (a) follows from the triangle inequality; (b) follows from [22], [24], and [25]; and (c) follows from the assumption \( \delta \geq 4 \). This completes the proof of Theorem 4.

**E. Concentration of MI Density**

In order to establish the MI and MMSE relationships used in our proof, we need to show that certain functions of the random tuple \( (X^n, W^n, A^n) \) concentrate about their expectations.

Our first result bounds the variation in the mutual information corresponding to the measurement matrix. Let \( I_{m,n}(A^n) \) denote the MI sequence as a function of the random matrix \( A^n \). The following result follows from the Gaussian Poincaré inequality and the multivariate I-MMSE relationship. The proof is given in Appendix B-E.

**Lemma 10.** Under Assumptions 1 and 2, the variance of the MI with respect to the measurement matrix satisfies
\[
\text{Var}(I_{m,n}(A^n)) \leq \min \left\{ \left( \text{Var}(X) \right)^2 m, \frac{n^2}{(m-n-1)^+} \right\}
\]

An important consequence of Lemma 10 is that the variance of the normalized mutual information \( \frac{1}{n} I_{m,n}(A^n) \) converges to zero as \( max(m,n) \) increases to infinity.

Next, we focus on the concentration of the mutual information density, which is a random variable whose expectation is equal to the mutual information.
Definition 4. Given a distribution $P_{X,Y,Z}$, the conditional mutual information density between $X$ and $Y$ given $Z$ is defined as

$$i(X;Y|Z) \triangleq \log \left( \frac{dP_{X,Y|Z}(X,Y|Z)}{d(P_{X|Z}(X|Z) \times P_Y(Z|Y,Z))} \right),$$

where $(X,Y,Z) \sim P_{X,Y,Z}$. This is well-defined because a joint distribution is absolutely continuous with respect to the product of its marginals.

The mutual information density satisfies many of the same properties as mutual information, such as the chain rule and invariance to one-to-one transformations; see [36, Chapter 5.5]. For this compressed sensing problem, the mutual information density can be expressed in terms of the density functions $f_{Y^n|X^n,A^n}$ and $f_{Y^m|A^m}$, which are guaranteed to exist because of the additive Gaussian noise:

$$i(X^n;Y^m|A^m) = \log \left( \frac{\int f_{Y^n|X^n,A^n}(Y^m|X^n,A^m) \, dY^n \, dA^n}{\int f_{Y^m|A^m}(Y^m|A^m) \, dY^m \, dA^m} \right).$$

The next result bounds the variance of the mutual information density in terms of the fourth moment of the signal distribution and the problem dimensions. The proof is given in Appendix B-G.

Lemma 11. Under Assumptions 1 and 2, the variance of the MI density satisfies

$$\text{Var}(i(X^n;Y^m|A^m)) \leq C_B \cdot \left(1 + \frac{m}{n}\right)^2 n.$$

IV. PROOF OF THEOREM 2

This section describes the proof of Theorem 2. An outline of the dependences between various steps is provided in Figure 2.

A. Further Definitions

The conditional distribution induced by the data $(Y^m, A^m)$ plays an important role and is referred to throughout as the posterior distribution. The optimal signal estimate with respect to squared error is given by the mean of the posterior distribution, and the squared error associated with this estimate is denoted by

$$\mathcal{E}_{m,n} = \frac{1}{n} ||X^n - \mathbb{E}[X^n | Y^m, A^m]||^2.$$

The conditional expectation of the squared error with respect to the posterior distribution is referred to as the posterior variance and is denoted by

$$V_{m,n} = \mathbb{E}[\mathcal{E}_{m,n} | Y^m, A^m].$$

Both $\mathcal{E}_{m,n}$ and $V_{m,n}$ are random variables. By construction, their expectations are equal to the MMSE, that is

$$M_{m,n} = \mathbb{E}[V_{m,n}] = \mathbb{E}[\mathcal{E}_{m,n}].$$

Next, recall that the MI difference sequence can be expressed in terms of the mutual information between the signal and a new measurement:

$$I_{m,n}' = I(X^n;Y_{m+1}^m | Y^m, A^{m+1}).$$

The MI difference density is defined to be the random variable

$$J_{m,n} = i(X^n;Y_{m+1}^m | Y^m, A^{m+1}),$$

where the mutual information density is defined in Definition 4. The conditional expectation of the MI difference density with respect to the posterior distribution is referred to as the posterior MI difference and is denoted by

$$J_{m,n} = \mathbb{E}[i(X^n;Y_{m+1}^m | Y^m, A^{m+1}) | Y^m, A^m].$$

Both $J_{m,n}$ and $J_{m,n}'$ are random variables. By construction, their expectations are equal to the MI difference, that is

$$\mathbb{E}[J_{m,n}] = \mathbb{E}[J_{m,n}'] = I_{m,n}'.$$

A summary of this notation is provided in Table I.

The next result shows that the moments of the square error and MI difference density can be bounded in terms of the fourth moment of the signal distribution. The proof is given in Appendix C-A.

Lemma 12. Under Assumptions 1 and 2,

$$\mathbb{E}[\mathcal{E}_{m,n}^2] \leq C \cdot B \quad (26)$$
$$\mathbb{E}[J_{m,n}^2] \leq C \cdot (1 + B) \quad (27)$$
$$\mathbb{E}[Y_{m+1}^4] \leq C \cdot (1 + B) \quad (28)$$
$$\mathbb{E}[Y_{m+1}^4 - \tilde{Y}_{m+1}^4] \leq C \cdot (1 + B), \quad (29)$$

where $\tilde{Y}_{m+1} = \mathbb{E}[Y_{m+1} | Y^m, A^m]$. 
B. Weak Decoupling

The posterior distribution of the signal cannot, in general, be expressed as the product of its marginals since the measurements introduce dependence between the signal entries. Nevertheless, it has been observed that in some cases, the posterior distribution satisfies a decoupling principle, in which the posterior distribution on a small subset of the signal entries is well approximated by the product of the marginals on that subset. One way to express this decoupling is to say that, for any fixed index set \( \{i_1, \ldots, i_L\} \) with \( L \ll n \), the random posterior distribution satisfies

\[
P_{X_{i_1}, \ldots, X_{i_L} | Y^m, A^m} \approx \prod_{f=1}^{L} P_{X_{i_f} | Y^m, A^m},
\]

with high probability with respect to the data \( (Y^m, A^m) \).

One of the main ideas in our proof is to use decoupling to show that the MI and MMSE sequences satisfy certain relationships. For the purposes of our proof, it is sufficient to work with a weaker notion of decoupling that depends only on the statistics of the pairwise marginals of the posterior distribution.

**Definition 5.** The posterior signal distribution \( P_{X^n | Y^m, A^m} \) satisfies weak decoupling if

\[
E[|E_{m,n} - V_{m,n}|] \to 0
\]

and

\[
\frac{1}{n} E[\|\text{Cov}(X^n | Y^m, A^m)\|_F] \to 0.
\]

as \( m \) and \( n \) increase to infinity.

The first condition in the definition of weak decoupling says that the magnitude of the squared error must concentrate about its conditional expectation. The second condition says that the average correlation between the signal entries under the posterior distribution is converging to zero. Note that both of these conditions are satisfied a priori in the case of \( m = 0 \) measurements, because that prior signal distribution is i.i.d. with finite fourth moments.

The next result provides several key identities, which show that certain properties of the posterior distribution can be expressed in terms of the second order statistics of new measurements. This result does not require Assumption 2, and thus holds generally for any prior distribution on \( X^n \). The proof is given in Appendix C-B.

**Lemma 13.** Under Assumption 1, the following identities hold for all integers \( m < i < j \):

(i) The posterior variance satisfies

\[
V_{m,n} = E_{A_i} [\text{Var}(Y_i | Y^m, A^m, A_j)] - 1.
\]  

(ii) The posterior covariance matrix satisfies

\[
\frac{1}{n} E[\|\text{Cov}(X^n | Y^m, A^m)\|_F] \to 0.
\]

(iii) The conditional variance of \( \sqrt{1 + E_{m,n}} \) satisfies

\[
\frac{1}{n} E[\|\text{Cov}(X^n | Y^m, A^m)\|_F] \to 0.
\]

C. Gaussianness of New Measurements

The centered measurement \( \bar{Y}_{m+1} \) is defined to be the difference between a new measurement and its conditional expectation given the previous data:

\[
\bar{Y}_{m+1} \triangleq Y_{m+1} - E[Y_{m+1} | Y^m, A^{m+1}]
\]

Conditioned on the data \( (Y^m, A^{m+1}) \), the centered measurement provides the same information as \( Y_{m+1} \), and thus the posterior MI difference and the MI difference can be expressed equivalently as

\[
J_m = E_i [I(X^n; \bar{Y}_{m+1} | Y^m, A^{m+1}) | Y^m, A^m]
\]

\[
I'_m = I(X^n; \bar{Y}_{m+1} | Y^m, A^{m+1}).
\]

Furthermore, by the linearity of expectation, the centered measurement can be viewed as a noisy linear projection of the signal error:

\[
\bar{Y}_{m+1} = \langle A_{m+1}, \bar{X}^n \rangle + W_{m+1},
\]

where \( \bar{X}^n = X^n - E[X^n | Y^m, A^m] \). Since the measurement vector \( A_{m+1} \) and noise term \( W_{m+1} \) are independent of everything else, the variance of the centered measurement can be related directly to the posterior variance \( V_m \) and the MMSE \( M_m \) via the following identities:

\[
\text{Var}(\bar{Y}_{m+1} | Y^m, A^m) = 1 + V_{m,n}
\]
\[
\text{Var}(\bar{Y}_{m+1}) = 1 + M_{m,n}.
\] (37)

Identity (36) follows immediately from Lemma 13. Identity (37) follows from the fact that the centered measurement has zero mean, by construction, and thus its variance is equal to the expectation of (36).

At this point, the key question for our analysis is the extent to which the conditional distribution of the centered measurement can be approximated by a zero-mean Gaussian distribution. We focus on two different measures of non-Gaussianness. The first measure, which is referred to as the posterior non-Gaussianness, is defined by the random variable

\[
\Delta_{m,n}^p \triangleq \mathbb{E}_{A_{m+1}} \left[ D_{KL} \left( P_{Y_{m+1} \mid A_{m+1}} \left\| \mathcal{N}(0, 1 + M_{m,n}) \right\| \right) \right].
\]

This is the Kullback–Leibler divergence with respect to the Gaussian distribution whose variance is matched to the marginal variance of \( Y_{m+1} \) given the data \( Y^{m}, A^{m} \).

The second measure, which is referred to simply as the non-Gaussianness, is defined by

\[
\Delta_{m,n} \triangleq \mathbb{E} \left[ D_{KL} \left( P_{Y_{m+1} \mid Y^m, A^{m+1}} \left\| \mathcal{N}(0, 1 + M_{m,n}) \right\| \right) \right].
\]

Here, the expectation is taken with respect to the tuple \( (Y^m, A^{m+1}) \) and the comparison is with respect to the Gaussian distribution whose variance is matched to the marginal variance of \( Y_{m+1} \).

The connection between the non-Gaussianness of the centered measurement and the relationship between the mutual information and MMSE sequences is given by the following result. The proof is given in Appendix C-E

**Lemma 15.** Under Assumption 1, the posterior non-Gaussianness and the non-Gaussianness satisfy the following identities:

\[
\Delta_{m,n} = \frac{1}{2} \log(1 + V_{m,n} - J_{m,n}) - I_{m,n} \quad \text{(38)}
\]

\[
\Delta_{m,n}^p = \frac{1}{2} \log(1 + M_{m,n} - I_{m,n}) \quad \text{(39)}
\]

Identity (39) shows the integral relationship between mutual information and MMSE in Theorem 2 can be stated equivalently in terms of the non-Gaussianness of the centered measurements. Furthermore, by combining (38) with (39), we see that the non-Gaussianness can be related to the expected posterior non-Gaussianness using the following decomposition:

\[
\Delta_{m,n} = \mathbb{E} \left[ \Delta_{m,n}^p \right] + \frac{1}{2} \mathbb{E} \left[ \log \left( \frac{1 + M_{m,n}}{1 + V_{m,n}} \right) \right].
\] (40)

The rest of this subsection is focused on bounding the expected posterior non-Gaussianness. The second term on the right-hand side of (40) corresponds to the deviation of the posterior variance and is considered in the next subsection.

The key step in bounding the posterior non-Gaussianness is provided by the following result, which bounds the expected Kullback–Leibler divergence between the conditional distribution of a random projection and a Gaussian approximation.

**Lemma 16.** (35). Let \( U \) be an \( n \)-dimensional random vector with mean zero and \( \mathbb{E}[\|U\|^4] < \infty \), and let \( Y = (A, U) + W \), where \( A \sim \mathcal{N}(0, \frac{1}{n} I_n) \) and \( W \sim \mathcal{N}(0, 1) \) are independent.

Then, the expected KL divergence between \( P_{Y \mid A} \) and the Gaussian distribution with the same mean and variance as \( P_{Y} \) satisfies

\[
\mathbb{E} \left[ D_{KL} \left( P_{Y \mid A} \left\| \mathcal{N}(0, \text{Var}(Y)) \right\| \right) \right] 
\leq \frac{1}{2} \mathbb{E} \left[ \frac{1}{n} \|U\| - \frac{1}{n} \mathbb{E}[\|U\|^2] \right] + C \cdot \left( \frac{1}{n} \mathbb{E}[\|U\|^4] \right)^{\frac{1}{2}}.
\]

Combining Lemma 19 with Lemma 17 leads to the following result, which bounds the expected posterior non-Gaussianness in terms of the second order MI difference. The proof is given in Appendix C-E.

**Lemma 17.** Under Assumptions 1 and 2, the expected posterior non-Gaussianness satisfies

\[
\mathbb{E} \left[ \Delta_{m,n}^p \right] \leq C_B \cdot |I_{m,n}|^{\frac{1}{2n}}.
\]

**D. Concentration of Posterior Variance**

We now turn our attention to the second term on the right-hand side of (40). By the concavity of the logarithm, this term is nonnegative and measures the deviation of the posterior variance about its expectation.

We begin with the following result, which provides useful bounds on the deviation of the posterior variance. The proof is given in Appendix C-E.

**Lemma 18.** Under Assumption 2, the posterior variance satisfies the following inequalities:

\[
\mathbb{E} \left[ \log \left( \frac{1 + M_{m,n}}{1 + V_{m,n}} \right) \right] \leq \mathbb{E}[|V_{m,n} - M_{m,n}|] 
\leq C_B \cdot \sqrt{\inf_{t \in \mathbb{R}} \mathbb{E}\left[ \frac{1}{2} \log(1 + V_{m,n}) - t \right]}.
\] (41)

The next step is to bound the right-hand side of (41). Observe that by Lemma 19, the term \( \frac{1}{2} \log(1 + V_{m,n}) \) can be expressed in terms of the posterior non-Gaussianness and the posterior MI difference. Accordingly, the main idea behind our approach is to show that the deviation of this term can be upper bounded in terms of deviation of the posterior MI difference.

Rather than working with the sequences \( V_{m,n} \) and \( J_{m,n} \) directly, however, we bound the averages of these terms corresponding to a sequence of \( \ell \) measurements, where \( \ell \) is an integer that is chosen at the end of the proof to yield the tightest bounds. The main reason that we introduce this averaging is so that we can take advantage of the bound on the variance of the mutual information density given in Lemma 11.

The key technical results that we need are given below. Their proof are given in Appendices C-G and C-H.

**Lemma 19.** Under Assumptions 1 and 2, the posterior variance satisfies

\[
\frac{1}{\ell} \sum_{k=m}^{m+\ell-1} \mathbb{E}[|V_{m+k} - V_k|] \leq C_B \cdot |I'_{m,n} - I'_{m+\ell-1,n}|^{\frac{1}{2}},
\]

for all \((\ell, m, n) \in \mathbb{N}^3\).
Lemma 20. Under Assumptions 1 and 2, the posterior MI difference satisfies
\[
\inf_{t \in \mathbb{R}} \mathbb{E} \left[ \frac{1}{L} \sum_{k=m}^{m+L-1} J_k - t \right] \leq C_B \cdot \left[ \left( 1 + \frac{m}{n} \right) \frac{\sqrt{\ell}}{\sqrt{n}} + \frac{1}{\sqrt{n}} \right],
\]
for all \((\ell, m, n) \in \mathbb{N}^3\).

Finally, combining Lemmas 17, 19, and 20 leads to the following result, which bounds the deviation of the posterior variance in terms of the MI difference sequence. The proof is given in Appendix C.

Lemma 21. Under Assumptions 1 and 2, the posterior variance satisfies,
\[
\mathbb{E}[\|V_{m,n} - M_{m,n}\|] \leq C_B \cdot \left[ \left| I_{m,n}^{''} \right|^{\frac{1}{4n}} + \left| I_{m,n}^{'} - I_{m+\ell,n}^{'} \right|^{\frac{1}{4n}} \right.
+ \left( 1 + \frac{m}{n} \right) \frac{\sqrt{\ell}}{\sqrt{n}} \frac{1}{n^{\frac{1}{2}}} + n^{-\frac{1}{2}},
\]
for all \((\ell, m, n) \in \mathbb{N}^3\).

E. Final Steps in Proof of Theorem 2

The following result is a straightforward consequence of Identity (40) and Lemmas 17 and 21. The proof is given in Appendix C.

Lemma 22. Under Assumptions 1 and 2, the non-Gaussianity of new measurements satisfies the upper bound
\[
\Delta_{m,n} \leq C_B \cdot \left[ \left| I_{m,n}^{''} \right|^{\frac{1}{4n}} + \left| I_{m,n}^{'} - I_{m+\ell,n}^{'} \right|^{\frac{1}{4n}} \right.
+ \left( 1 + \frac{m}{n} \right) \frac{\sqrt{\ell}}{\sqrt{n}} \frac{1}{n^{\frac{1}{2}}} \frac{1}{n^{\frac{1}{2}}},
\]
where \(\ell_n = \lceil n^{\frac{1}{2}} \rceil\).

We now show how the proof of Theorem 2 follows as a consequence of Identity (49) and Lemma 22. Fix any \(n \in \mathbb{N}\) and \(\delta \in \mathbb{R}_+\) and let \(m = \lfloor \delta n \rfloor\) and \(L = \lfloor n^{\frac{1}{2}} \rfloor\). Then, we can write
\[
\int_0^\delta \left| T_n^\gamma(\gamma) - \frac{1}{2} \gamma \right| \, d\gamma \leq \frac{m-1}{n} \sum_{k=0}^{m-1} \int_0^{\frac{k+1}{n}} \left| T_n^\gamma(\gamma) - \frac{1}{2} \gamma \right| \, d\gamma
= \frac{1}{n} \sum_{k=0}^{m-1} \left| I_{k,n}^{'} - \frac{1}{2} \log(1 + M_{k,n}) \right|
= \frac{1}{n} \sum_{k=0}^{m-1} \Delta_{k,n}
\leq \frac{C_B}{n} \sum_{k=0}^{m-1} \left[ \left| I_{k,n}^{''} \right|^{\frac{1}{4n}} + \left| I_{k,n}^{'} - I_{k+\ell,n}^{'} \right|^{\frac{1}{4n}} \right.
\]
+ \left( 1 + \frac{k}{n} \right) \frac{1}{n} \frac{1}{n^{\frac{1}{2}}} \frac{1}{n^{\frac{1}{2}}},
\]
where: (a) follows from the definitions of \(T_n^\gamma(\delta)\) and \(M_n(\delta)\); (b) follows from Identity (49); and (c) follows from Lemma 22.

To further bound the right-hand side of (42), observe that
\[
\frac{1}{n} \sum_{k=0}^{m-1} \left| I_{k,n}^{'} \right|^{\frac{1}{4n}} \leq \frac{m}{n} \left( \sum_{k=0}^{m-1} \left| I_{k,n}^{'} \right| \right)^{\frac{1}{4n}} \leq \frac{m}{n} \left( \frac{1}{2} \log(1 + M_{n}) \right)^{\frac{1}{4n}},
\]
where: (a) follows from Hölder’s inequality; (b) follows from the fact that \(I_{m,n}^{''}\) is non-positive; (c) follows from the fact that \(I_{m,n}^{'}\) is non-increasing in \(m\); and (d) follows from the fact that \(I_{1,n}^{'}\) is upper bounded by a constant that depends only on \(B\).

Plugging (43), (44), and (45) back into (42) and retaining only the dominant terms yields
\[
\int_0^\delta \left| T_n^\gamma(\gamma) - \frac{1}{2} \log(1 + M_n(\gamma)) \right| \, d\gamma \leq C_B \cdot (1 + \delta) \frac{1}{n} \frac{1}{n^{\frac{1}{2}}} \frac{1}{n^{\frac{1}{2}}},
\]
This completes the proof of Theorem 2.

V. PROOF OF THEOREM 3

A. MMSE Fixed-Point Relationship

This section shows how the MMSE can be bounded in terms of a fixed-point equation defined by the single-letter MMSE function of the signal distribution. At a high level, our approach focuses on the MMSE of an augmented measurement model, which contains an extra measurement and extra signal entry, and shows that this augmented MMSE can be related to \(M_n\) in two different ways.

For a fixed signal length \(n\) and measurement number \(m\), the augmented measurement model consists of the measurements \((Y^m, A^m)\) plus an additional measurement given by
\[
Z_{m+1} = Y_{m+1} + \sqrt{G_{m+1}} X_{n+1},
\]
where \(G_m = \frac{1}{2} \chi_m^2\) has a scaled chi-square distribution and is independent of everything else. The observed data is given by the tuple \((Y^m, A^m, D_{m+1})\) where
\[
D_{m+1} = (Z_{m+1}, A_{m+1}, G_{m+1}).
\]
The augmented MMSE $\tilde{M}_{m,n}$ is defined to be the average MMSE of the first $n$ signal entries given this data:

$$\tilde{M}_{m,n} \triangleq \frac{1}{n} \text{mmse}(X^n | Y^m, A^m, D_{m+1}).$$

The augmented measurement $Z_{m+1}$ is a noisy version of the measurement $Y_{m+1}$. Therefore, as far as estimation of the signal $X^n$ is concerned, the augmented measurements are more informative than $(Y^m, A^m)$, but less informative than $(Y_{m+1}, A_{m+1})$. An immediate consequence of the data processing inequality for MMSE [34, Proposition 4], is that the augmented MMSE is sandwiched between the MMSE sequence:

$$M_{m+1,n} \leq \tilde{M}_{m+1,n} \leq M_{m,n}. \quad (46)$$

The following result follows immediately from (46) and the smoothness of the posterior variance given in Lemma 19. The proof is given in Appendix D-A.

**Lemma 23.** Under Assumptions 1 and 2, the augmented MMSE $\tilde{M}_{m,n}$ and the MMSE $M_{m,n}$ satisfy

$$|\tilde{M}_{m,n} - M_{m,n}| \leq C_B \cdot |I_{m,n}|^{\frac{1}{2}}. \quad (47)$$

The next step in the proof is to show that $\tilde{M}_{m}$ can also be expressed in terms of the single-letter MMSE function $\text{mmse}_X(s)$. The key property of the augmented measurement model that allows us to make this connection is given by the following result. The proof is given in Appendix D-B.

**Lemma 24.** Under Assumptions 1 and 2, the augmented MMSE can be expressed equivalently in terms of the last signal entry:

$$\tilde{M}_{m,n} = \text{mmse}(X_{n+1} | Y^m, A^m, D_{m+1}). \quad (48)$$

To see why the characterization in (48) is useful note that the first $m$ measurements $(Y^m, A^m)$ are independent of $X_{n+1}$. Thus, as far as estimation of $X_{n+1}$ is concerned, the relevant information provided by these measurements is summarized by the conditional distribution of $Y_{m+1}$ given $(Y^m, A_{m+1})$. This observation allows us to leverage results from Section IV-C which focused on the non-Gaussianity of this distribution. The proof of the following result is given in Section D-C.

**Lemma 25.** Under Assumptions 1 and 2, the augmented MMSE and the MMSE satisfy

$$|\tilde{M}_{m,n} - \text{mmse}_X\left(\frac{m/n}{1 + \tilde{M}_{m,n}}\right)| \leq C_B \cdot \left(\sqrt{\Delta_{m,n}} + \frac{\sqrt{m}}{n}\right),$$

where $\Delta_{m,n}$ is the non-Gaussianity of new measurements.

**B. Final Steps in Proof of Theorem 3**

Fix any $n \in \mathbb{N}$ and $\delta \in \mathbb{R}^+$ and let $m = \lfloor \delta n \rfloor$. Then, we can write

$$\int_0^\delta \left| M_n(\gamma) - \text{mmse}_X\left(\frac{\gamma}{1 + M_n(\gamma)}\right) \right| d\gamma \leq \sum_{k=0}^{m-1} \int_{\frac{k}{n}}^{\frac{k+1}{n}} \left| M_n(\gamma) - \text{mmse}_X\left(\frac{\gamma}{1 + M_n(\gamma)}\right) \right| d\gamma \leq \sum_{k=0}^{m-1} \int_{\frac{k}{n}}^{\frac{k+1}{n}} \left| M_n(\gamma) - \text{mmse}_X\left(\frac{\gamma}{1 + M_n(\gamma)}\right) \right| d\gamma \leq \frac{1}{n} \sum_{k=0}^{m-1} \left( M_{k,n} - \text{mmse}_X\left(\frac{k/n}{1 + M_{k,n}}\right) \right) + C_B \cdot \left(1 + \frac{\delta}{n}\right) \cdot \frac{\sqrt{k}}{n} \cdot \left(1 + \frac{\sqrt{m}}{n}\right),$$

where: (a) follows from definition of $M_n(\delta)$; (b) follows from the triangle inequality and Lemma 23; and (c) follows from Lemmas 23 and 25. To further bound the right-hand side of (49), observe that, by the same steps that led to Inequality (43),

$$\frac{1}{n} \sum_{k=0}^{m-1} |I'_{k,n}|^{\frac{1}{2}} \leq C_B \cdot (1 + \delta)^{\frac{1}{2}} n^{-\frac{1}{4}}. \quad (50)$$

Furthermore,

$$\frac{1}{n} \sum_{k=0}^{m-1} |\Delta_{k,n}| \leq C_B \cdot (1 + \delta)^{\frac{1}{2}} \sqrt{(1 + \delta)^{\frac{1}{2}} n^{-\frac{1}{4}}},$$

and (b) follows from proof of Theorem 2. Finally,

$$\frac{1}{n} \sum_{k=0}^{m-1} \left( \frac{\sqrt{k}}{n} + \frac{1}{n} \right) \leq \frac{m(1 + \sqrt{m} - 1)}{2n^2} \leq (1 + \delta)^{\frac{1}{2}} n^{-\frac{1}{4}}. \quad (52)$$

Plugging (50), (51), and (52), back into (49) and keeping only the dominant terms leads to

$$\int_0^\delta \left| M_n(\gamma) - \text{mmse}_X\left(\frac{\gamma}{1 + M_n(\gamma)}\right) \right| d\gamma \leq C_B \cdot (1 + \delta)^{\frac{1}{2}} n^{-\frac{1}{4}}.$$
The function $\delta_{RS}$ is continuous and non-increasing because $M_{RS}(\delta)$ correspond to flat sections in $\delta_{RS}(z)$.

Using these definitions we can now provide a formal definition of the single-crossing property.

**Definition 6** (Single-Crossing Property). A signal distribution $P_X$ has the single-crossing property if $\delta_{RS} - \delta_{FP}$ has at most one zero-crossing. In other words, there exists $z_* \in \mathbb{R}_+$ such that $\delta_{RS} - \delta_{FP}$ is nonpositive or nonnegative on $[0,z_*)$ and nonpositive or nonnegative on $[z_*, \infty)$.

**Lemma 26.** If the signal distribution $P_X$ has the single-crossing property there exists a point $(z_*, \delta_*) \in FP$ such that

$$
\delta_{RS}(z) = \begin{cases} 
\max(\delta_{FP}(z), \delta_*), & \text{if } z \in [0, z_*) \\
\min(\delta_{FP}(z), \delta_*), & \text{if } z \in [z_*, \infty).
\end{cases}
$$

**Proof:** If $\delta_{RS}(z) = \delta_{FP}(z)$ for all $z \in \mathbb{R}_+$ then this representation holds for every point in FP because $\delta_{RS}$ is non-increasing. Alternatively, if there exists $(u_*, \delta_*) \in \mathbb{R}_+^2$ such that $\delta_* = \delta_{RS}(u_*) \neq \delta_{FP}(u_*)$ then it must be the case that the global minimum of $Q_*(z) \equiv R(\delta_*, z)$ is attained at more than one point. More precisely, there exists $z_1 < u_* < z_2$ such that

$$
Q_*(z_1) = Q_*(z_2) = \min Q_*(z),
$$

$$
Q_*(u) > \min Q_*(z) \quad \text{for some } u \in (z_1, z_2).
$$

To see why the second constraint follows from the assumption $\delta_{RS}(u_*) \neq \delta_{FP}(u_*)$, note that $Q_*(z)$ were constant over the interval $[z_1, z_2]$, that would mean that $Q_*(z) = R(z, \delta_*, z) = 0$ for all $z \in [z_1, z_2]$. This is equivalent to saying that every point on the line from $(\delta_*, z_1)$ to $(\delta_*, z_2)$ is on the fixed-point curve, which is a contradiction.

Now, since $\delta_{RS}(z)$ is non-increasing and equal to $\delta_*$ at both $z_1$ and $z_2$ we know that $\delta_{RS}(z) = \delta_*$ for all $z \in [z_1, z_2]$. Furthermore, since $z_1$ and $z_2$ are minimizers of $R(\delta, z)$, we also know that $\delta_{FP}(z_1) = \delta_{FP}(z_2) = \delta_*$. Next, we will show that the the function $\delta_{FP}(z) - \delta_*$ must have at least one negative-to-positive zero-crossing on $(z_1, z_2)$. Recall that the function $Q_*(z)$ is continuous, has global minima at $z_1$ and $z_2$, and it not constant over $[z_1, z_2]$. Therefore, it must attain a local maximum on the open interval $(z_1, z_2)$. Since it is continuously differentiable, this means that there exists $u_1, u_2 \in (z_1, z_2)$ with $u_1 < u_2$ such that $Q'_*(u_1) > 0$ and $Q'_*(u_2) < 0$. The sign changes in $Q_*(z)$ can be related to the sign changes in $\delta_{FP}(z) - \delta_*$ by noting that

$$
\text{sgn}(Q_*(z)) = \begin{cases} 
\text{sgn} \left( z - \text{mmse}_X \left( \frac{\delta_*}{1 + z} \right) \right), & \text{if } z \in [0, z_*) \\
\text{sgn} \left( \text{mmse}_X^{-1}(z) - \frac{\delta_*}{1 + z} \right), & \text{if } z \in [z_*, \infty)
\end{cases}
$$

where (a) follows from (21) the fact that $\delta_*$ can be taken to be strictly positive and (b) follows from the fact that $\text{mmse}_X(s)$ is strictly decreasing. As a consequence, we see that $\delta_{FP}(u_1) < \delta_*$ and $\delta_{FP}(u_2) > \delta_*$, and thus $\delta_{FP}(z) - \delta_*$ has at least one negative-to-positive zero-crossing on the interval $(z_1, z_2)$.

At this point, we have shown that every tuple $(\delta_*, z_1, z_2)$ satisfying (53) and (54) leads to at least one negative-to-positive zero-crossing of $\delta_{FP} - \delta_{RS}$. Therefore, if the signal distribution has the single-crossing property, there can be at most one such tuple. This implies that $\delta_{FP}(z) = \delta_{RS}(z)$ for all $z \in [0, z_1] \cup [z_2, \infty)$. Furthermore, by the continuity of $\delta_{FP}$, there exists a point $z_* \in (u_1, z_2)$ such that $\delta_{FP}(z_*) = \delta_*$ and

$$
z \leq z_* \implies \delta_{RS}(z) \geq \delta_{FP}(z)
$$

$$
z \geq z_* \implies \delta_{RS}(z) \leq \delta_{FP}(z).
$$

Combining these observations leads to the stated result. 

Next, for each $g \in V$, we use $\delta_g(z) = g^{-1}(z)$ to denote the functional inverse. The function $\delta_g$ is continuous and non-increasing because $g$ is strictly decreasing.

**Lemma 27.** If the signal distribution $P_X$ has the single-crossing property then, for every $g \in V$, the function $\delta_g$ is either an upper bound or lower bound on $\delta_{RS}$.

**Proof:** Let $(\delta_*, z_*)$ be the point described in Lemma 26. Since $\delta_*$ is non-increasing, we have $\delta_g(z) \geq \delta_g(z_*)$ for all $z \in [0, z_1]$ and $\delta_g(z) \leq \delta_g(z_*)$ for all $z \in [z_*, \infty)$. Combining these inequalities with the fact that $\delta_*$ is lower bounded by the lower envelop of the fixed-point curve leads to

$$
\delta_g(z) \geq \begin{cases} 
\min \max(\delta_{FP}(u), \delta_g(z_*)), & \text{if } z \in [0, z_*] \\
\min \delta_{RS}(u), & \text{if } z \in [z_*, \infty).
\end{cases}
$$

Therefore, if $\delta_g(z) \geq \delta_*$, we see that

$$
\delta_g(z) \geq \begin{cases} 
\min \max(\delta_{FP}(u), \delta_*), & \text{if } z \in [0, z_*) \\
\min \min(\delta_{FP}(u), \delta_*), & \text{if } z \in [z_*, \infty).
\end{cases}
$$

(a)

$$
\delta_{RS}(z),
$$

(b)

where (a) follows from Lemma 26 and (b) follows from the fact that $\delta_{RS}$ is non-increasing. Alternatively, if $\delta_g(z) \leq \delta_*$ then a similar argument can be used to show that $\delta_g(z) \leq \delta_{RS}(z)$ for all $z \in \mathbb{R}_+$.

**Lemma 28.** If the signal distribution $P_X$ has the single-crossing property, then $G$ is equal to the equivalence class of functions in $V$ that are equal to $M_{RS}$ almost everywhere.

**Proof:** Recall that $G$ is the set of all functions $g \in V$ that satisfy the boundary condition

$$
\lim_{\delta \to \infty} \left| \int_0^\delta \frac{1}{2} \log(1 + g(\gamma))d\gamma - I_{RS}(\delta) \right| = 0.
$$

Furthermore, for each $g \in V$ and $\delta \in \mathbb{R}_+$, we can write

$$
\int_0^\delta \frac{1}{2} \log(1 + g(\gamma))d\gamma - I_{RS}(\delta) \equiv \int_0^\delta \frac{1}{2} \log(1 + M_{RS}(\gamma))d\gamma - \int_0^\delta \frac{1}{2} \log(1 + g(\gamma))d\gamma
$$

where (a) follows from (21) the fact that $\delta_*$ can be taken to be strictly positive and (b) follows from the fact that $\text{mmse}_X(s)$ is strictly decreasing. As a consequence, we see that $\delta_{FP}(u_1) < \delta_*$ and $\delta_{FP}(u_2) > \delta_*$, and thus $\delta_{FP}(z) - \delta_*$ has at least one negative-to-positive zero-crossing on the interval $(z_1, z_2)$. 

The function $\delta_{RS}$ is continuous and non-increasing because $M_{RS}(\delta)$ correspond to flat sections in $\delta_{RS}(z)$.
(b) \[ \int_0^\delta \left[ \frac{1}{2} \log(1 + M_{RS}(\gamma)) - \frac{1}{2} \log(1 + g(\gamma)) \right] \, d\gamma, \quad (56) \]

where (a) follows from \[5\] and (b) follows from the monotonicity of \( g \) and \( M_{RS} \) and Lemma \[27\]. Combining \[55\] and \[56\], we see that, for all \( g \in \mathcal{G} \),

\[ \int_0^\infty \left[ \frac{1}{2} \log(1 + M_{RS}(\gamma)) - \frac{1}{2} \log(1 + g(\gamma)) \right] \, d\gamma = 0, \]

and thus \( M_{RS} \) and \( g \) are equal almost everywhere. \[\Box\]

**B. Convergence of Subsequences**

For each \( n \in \mathbb{N} \), the function \( M_n \) is a non-increasing function from \( \mathbb{R}_+ \) to \( \mathbb{R}_+ \). Convergence of the sequence \( M_n \) can be treated in a few different ways. In our original approach \[37\], we focused on the Lévy metric \[38\, Ch. 2\]. Here, we present a more direct argument based on the Helly Selection Theorem \[39\, Thm. 12\].

First, we let \( L^1([0, S]) \) represent the standard Banach space of Lebesgue integrable functions from \([0, S]\) to \( \mathbb{R} \) with norm

\[ \int_0^S |f(\delta)| \, d\delta. \]

In this space, two functions \( f, g \) are called equivalent if they are equal almost-everywhere (i.e., \( f \int_0^S \frac{d\delta}{d\gamma} = 0 \)).

Next, we recall that monotone functions are continuous almost everywhere (e.g., except for a countable set of jump discontinuities) \[40\]. Thus, \( f, g \) are equivalent if and only if they are equal at all points of continuity.

The following lemmas outline our approach to convergence.

**Lemma 29.** Under Assumptions 1 and 2, for any \( S > 0 \) and any subsequence of \((M_n, I_n)\), there is a further subsequence (whose index is denoted by \( n' \)) and some \( g \in \mathcal{G} \) such that

\[ \lim_{n'} \int_0^S |M_{n'}(\delta) - g(\delta)| \, d\delta = 0 \]

\[ \lim_{n'} \int_0^S \left| I_{n'}(\delta) - \frac{1}{2} \log(1 + g(\delta)) \right| \, d\delta = 0. \]

**Proof:** For any \( S > 0 \) and each \( n \in \mathbb{N} \), the restriction of \( M_n(\delta) \) to \( \delta \in [0, S] \) is non-increasing and uniformly bounded by \( M_n(0) = \text{Var}(X) \). Since \( M_n(\delta) \) is nonnegative and non-increasing, its total variation on \([0, T]\) equals \( M_n(0) - M_n(S) \leq \text{Var}(X) \) \[41\, Section 6.3\].

Based on this, the Helly Selection Theorem \[39\, Thm. 12\] shows that any subsequence of \( M_n \) contains a further subsequence that converges in \( L^1([0, S]) \). Let \( M_n' \) denote this further subsequence and \( M_* \) denote its limit so that

\[ \lim_{n'} \int_0^S |M_{n'}(\delta) - M_*(\delta)| \, d\delta = 0. \]

To simplify notation, we define the operator \( T : L^1([0, S]) \to L^1([0, S]) \) via \((Tf)(\delta) = \text{mmse}_X(\delta/(1 + f(\delta)))\). To analyze \( M_n(\delta) \), we observe that, for all \( n \), one has

\[ \int_0^S |M_n(\delta) - TM_n(\delta)| \, d\delta \leq \int_0^S |M_n(\delta) - M_*(\delta)| \, d\delta \]

\[ + \int_0^S \left| M_*(\delta) - TM_n(\delta) + TM_n(\delta) - TM_*(\delta) \right| \, d\delta \]

\[ \leq (1 + L_T) \int_0^S |M_*(\delta) - M_n(\delta)| \, d\delta \]

\[ + \int_0^S |M_n(\delta) - TM_*(\delta)| \, d\delta, \]

where \( L_T \) is the Lipschitz constant of \( T \). Under Assumption 2, one can use Lemma \[5\] to show that \( L_T \leq 4BS \). Since \( \int_0^S |M_*(\delta) - M_n(\delta)| \, d\delta \to 0 \) by construction and \( \int_0^S |M_n(\delta) - TM_*(\delta)| \, d\delta \to 0 \) by Theorem \[3\] taking the limit along this subsequence shows that \( M_* \) equals \( TM_* \) almost everywhere on \([0, S]\). As \( S \) was arbitrary, we see that \( M_* \) satisfies the first condition of Definition \[3\].

To establish the second condition of Definition \[3\] we focus on the sequence \( I_n \). Recall that each \( I_n \) is concave and differentiable, with derivative \( I_n' \). Also, the set \( \{I_n\} \) is uniformly bounded on \([0, S]\) and uniformly Lipschitz by \[8\], \[16\], and \[17\]. By the Arzelà-Ascoli theorem \[41\, Section 10.1\], this implies that any subsequence of \( I_n \) contains a further subsequence that converges uniformly on \([0, S]\). Moreover, the limiting function is concave and the further subsequence of derivatives also converges to the derivative of the limit function at each point where it is differentiable \[42\, Corollary 1.3.8\].

Thus, from any subsequence of \((M_n, I_n)\), we can choose a further subsequence whose index is denoted by \( n' \) such that \( \int_0^S |M_{n'}(\delta) - M_*(\delta)| \, d\delta \to 0 \) and \( I_{n'} \) converges uniformly on \([0, S]\) to a concave limit function \( I_* \). Moreover, the sequence of derivatives \( I_{n'}' \) also converges to \( I_*(\delta) \) at each point where \( I_* \) is differentiable. Since \( I \) is concave, it is differentiable almost everywhere and we have

\[ \lim_{n'} I_{n'}(\delta) = I_*(\delta) \]

almost everywhere on \([0, S]\). Since \( |I_{n'}(\delta) - I_*(\delta)| \) is bounded and converges to zero almost everywhere on \([0, S]\), we can apply the dominated convergence theorem to see also that \( \int_0^S |I_{n'}(\delta) - I_*(\delta)| \, d\delta \to 0 \). Next, we can apply Theorem \[2\] to see that

\[ \lim_{n'} \int_0^S \left| I_{n'}(\delta) - \frac{1}{2} \log(1 + M_{n'}(\delta)) \right| \, d\delta = 0. \]

Since \( \frac{1}{2} \log(1 + z) \) is Lipschitz in \( z \), one finds that

\[ \int_0^S \frac{1}{2} \log(1 + M_{n'}(\delta)) \, d\delta \to 0 \]

follows from the fact that \( \int_0^S |M_{n'}(\delta) - M_*(\delta)| \, d\delta \to 0 \). Along with the triangle inequality, this shows that \( I_{n'}(\delta) \) converges to \( \frac{1}{2} \log(1 + M_*(\delta)) \) almost everywhere on \([0, S]\). Since \( |I_{n'}(\delta) - \frac{1}{2} \log(1 + M_*(\delta))| \) is bounded and converges to zero almost everywhere on \([0, S]\), we can apply the dominated convergence theorem to see that

\[ I_*(S) = \lim_{n'} \int_0^S I_{n'}(\delta) \, d\delta = \int_0^S \frac{1}{2} \log(1 + M_*(\delta)) \, d\delta. \quad (57) \]

Next, we observe that Theorem \[4\] implies

\[ \lim_{n'} |I_{RS}(S) - I_{n'}(S)| \leq \frac{C}{S}. \]
for all $S \geq 4$. With \((57)\), this implies that
\[
\left| I_{RS}(S) - \int_0^S \frac{1}{2} \log (1 + M_*(\delta)) \, d\delta \right|
\leq |I_{RS}(S) - I_{n'}(S)| + \left| I_{n'}(S) - \int_0^S \frac{1}{2} \log (1 + M_*(\delta)) \, d\delta \right|
\leq \frac{C}{\sqrt{S}} + \epsilon_{n'},
\]
where $\lim_{n' \to \infty} \epsilon_{n'} = 0$. Taking the limit $n' \to \infty$ followed by the limit $S \to \infty$, we see
\[
\lim_{S \to \infty} \lim_{n' \to \infty} \left| I_{RS}(S) - \int_0^S \frac{1}{2} \log (1 + M_*(\delta)) \, d\delta \right| = 0
\]
and, thus, that $M_* \in \mathcal{G}$. Notice that we focus first on finite $S \in \mathbb{R}_+$ and then take the limit $S \to \infty$. This is valid because the functions $I(\delta)$ and $M_*(\delta)$ are defined for all $\delta \in \mathbb{R}_+$ but restricted to $[0, S]$ for the convergence proof.

Now, we can complete the proof of Theorem 1. The key idea is to combine Lemma 28 with Lemma 29. From these two results, it follows that, for any $S > 0$, every subsequence of $M_*(\delta)$ has a further subsequence that converges to $I_{RS}(\delta)$. This holds because the further subsequence must converge to some function in $\mathcal{G}$ (by Lemma 29) but there is only one function up to almost everywhere equivalence (by Lemma 28).

The final step is to realize that this is sufficient to prove that, for all $S > 0$, we have
\[
\lim_{n \to \infty} \int_0^S |M_{RS}(\delta) - M_{n}(\delta)| \, d\delta = 0.
\]
To see this, suppose that $M_{n}(\delta)$ does not converge to $M_{RS}(\delta)$ in $L^1([0, S])$. In this case, there is an $\epsilon > 0$ and an infinite subsequence $n(i)$ such that
\[
\int_0^S |M_{RS}(\delta) - M_{n(i)}(\delta)| \, d\delta > \epsilon
\]
for all $i \in \mathbb{N}$. But, applying Lemma 29 shows that $n(i)$ has a further subsequence (denoted by $n''$) such that
\[
\lim_{n''} \int_0^S |M_{RS}(\delta) - M_{n''}(\delta)| \, d\delta = 0.
\]
From this contradiction, one must conclude that $M_{n}(\delta)$ converges to $M_{RS}(\delta)$ in $L^1([0, S])$ for any $S > 0$.

VII. CONCLUSION

In this paper, we present a rigorous derivation of the fundamental limits of compressed sensing for i.i.d. signal distributions and i.i.d. Gaussian measurement matrices. We show that the limiting MI and MMSE are equal to the values predicted by the replica method from statistical physics. This resolves a well-known open problem.

APPENDIX A
USEFUL RESULTS

A. Basic Inequalities

We begin by reviewing a number of basic inequalities. For numbers $x_1, \cdots, x_n$ and $p \geq 1$, Jensen’s inequality combined with the convexity of $| \cdot |^p$ yields,
\[
|\sum_{i=1}^n x_i|^p \leq \sum_{i=1}^n |x_i|^p, \quad p \geq 1.
\]
In the special case $n = 2$ and $p \in \{2, 4\}$, we obtain
\[
(a + b)^2 \leq 2(a^2 + b^2)
\]
and
\[
(a + b)^4 \leq 8(a^4 + b^4).
\]

For random variables $X_1, \cdots, X_n$ and $p \geq 1$, a consequence of Minkowski’s inequality \([43, \text{Theorem } 2.16]\) is that
\[
E \left[ \sum_{i=1}^n X_i \right]^p \leq \left( \sum_{i=1}^n E[|X_i|^p] \right)^{\frac{p}{2}}, \quad p \geq 1.
\]
Also, for random variables $X$ and $Y$, an immediate consequence of Jensen’s inequality is that expectation of the absolute difference $|X - Y|$ can be upper bounded in terms of higher moments, i.e.,
\[
E[|X - Y|] \leq |E[X] - E[Y]| + \sqrt{\frac{1}{2} E[X^2] + E[Y^2]} E[|\log(X/Y)|].
\]

Sometimes, we need to bound the difference in terms of weaker measures of deviation between $X$ and $Y$. The following Lemma provides two such bounds that also depend on the moments of $X$ and $Y$.

Lemma 30. For nonnegative random variables $X$ and $Y$, the expectation of the absolute difference $|X - Y|$ obeys the following upper bounds:
\[
E[|X - Y|] \leq \sqrt{\frac{1}{2} E[X^2] + E[Y^2]} E[|\log(X/Y)|].
\]

Proof: We begin with (62). For any numbers $0 < x < y$, the difference $y - x$ can be upper bounded as follows:
\[
y - x = \int_x^y \frac{1}{\sqrt{u}} \, du
\]
\[
\leq \sqrt{\int_x^y u \, du} \sqrt{\int_x^y \frac{1}{u} \, du}
\]
\[
= \sqrt{\frac{1}{2} (y^2 - x^2) \log(y/x)}
\]
\[
\leq \sqrt{\frac{1}{2} (y^2 + x^2) \log(y/x)},
\]
where the first inequality is due to the Cauchy-Schwarz inequality. Thus, the absolute difference between $X$ and $Y$ obeys
\[
|X - Y| \leq \sqrt{\frac{1}{2} (X^2 + Y^2) \log(X/Y)}.
\]
Taking the expectation of both sides and using the Cauchy-Schwarz inequality leads to (62).

To prove (63), observe that the difference between between $X$ and $Y$ can be decomposed as

$$X - Y = (\sqrt{X} + \sqrt{Y})(\sqrt{X} - \sqrt{Y}).$$

Thus, by the Cauchy-Schwarz inequality,

$$\mathbb{E}[|X - Y|^2] = \sqrt{\mathbb{E}[(\sqrt{X} + \sqrt{Y})^2 \mathbb{E}[(\sqrt{X} - \sqrt{Y})^2]} \leq \sqrt{2(\mathbb{E}[X] + \mathbb{E}[Y])} \sqrt{\mathbb{E}[(\sqrt{X} - \sqrt{Y})^2]},$$

where the last step is due to (59).

**B. Variance Decompositions**

This section reviews some useful decompositions and bounds on the variance. As a starting point, observe that the variance of a random variable $X$ can be expressed in terms of an independent copy $X'$ according to

$$\text{Var}(X) = \frac{1}{2} \mathbb{E}[(X - X')^2].$$

This representation can extended to conditional variance, by letting $X_y$ and $X'_y$ denote independent draws from the conditional distribution $P_{X|Y=y}$, so that

$$\text{Var}(X|Y = y) = \frac{1}{2} \mathbb{E}[(X_y - X'_y)^2].$$

For a random draw of $Y$, it then follows that the random conditional variance of $X$ given $Y$ can be expressed as

$$\text{Var}(X|Y) = \frac{1}{2} \mathbb{E}[(X_Y - X'_Y)^2|Y],$$

where $X_Y$ and $X'_Y$ are conditionally independent draws from the random conditional distribution $P_{X|Y}(\cdot|Y)$.

Using this representation, the moments of the conditional variance can be bounded straightforwardly. For all $p \geq 1$,

$$E[|\text{Var}(X|Y)|^p] = \frac{1}{2^p} \mathbb{E}[[X - X']^2]^p} = (a)p \mathbb{E}[(X - X')^2]^p} \leq 2^p \mathbb{E}[(X - X')^2]^p} \leq 2^p \mathbb{E}[(X_Y - X'_Y)^2] + \mathbb{E}[(X'_Y)^2]} \leq 2^p \mathbb{E}[(X_Y - X'_Y)^2],$$

where (a) follows from Jensen’s inequality and the convexity of $|\cdot|^p$, (b) follows from (58), and (c) follows from the fact that $X_Y$ and $X'_Y$ both have the same distribution as $X$.

The law of total variance gives

$$\text{Var}(X) = \mathbb{E}[\text{Var}(X|Y)] + \text{Var}(\mathbb{E}[X|Y]).$$

As an immediate consequence, we obtain the data processing inequality for MMSE (see e.g. [34 Proposition 4]), which states that conditioning cannot increase the MMSE on average. In particular, if $X \rightarrow Y \rightarrow Z$ form a Markov chain, then

$$\text{mmse}(X|Y) \leq \text{mmse}(X|Z).$$

**C. Bounds using KL Divergence**

This section provides a number results that allow us to bound differences in expectations in terms of Kullback–Leibler divergence. One of the consequences of Lemma 31 (given below) is that random variables $X \sim P_X$ and $Y \sim P_Y$ with positive and finite second moments satisfy

$$\frac{\mathbb{E}[X] - \mathbb{E}[Y]}{\sqrt{2\mathbb{E}[X^2] + 2\mathbb{E}[Y^2]}} \leq \sqrt{D_{KL}(P_X \parallel P_Y)}.$$

We begin by reviewing some basic definitions (see e.g., [44 Section 3.3]). Let $P$ and $Q$ be probability measures with densities $p$ and $q$ with respect to a dominating measure $\lambda$. The Hellinger distance $d_H(P, Q)$ is defined as the $L_2$ distance between the square roots of the densities $\sqrt{p}$ and $\sqrt{q}$, and the squared Hellinger distance is upper bounded by the KL divergence

$$d_H^2(P, Q) = \int (\sqrt{p} - \sqrt{q})^2 d\lambda.$$

The Kullback–Leibler divergence (also known as relative entropy) is defined as

$$D_{KL}(P \parallel Q) = \int p \log \left(\frac{p}{q}\right) d\lambda.$$

The squared Hellinger distance is further bounded by the KL divergence

$$d_H^2(P, Q) \leq D_{KL}(P \parallel Q).$$

**Lemma 31.** Let $f$ be a function that is measurable with respect to $P$ and $Q$. Then

$$\left|\int f(dP - dQ)\right| \leq \sqrt{2 \int f^2(dP + dQ) \min\{\sqrt{D_{KL}(P \parallel Q)}, 1\}}.$$

**Proof:** Let $p$ and $q$ be the densities of $P$ and $Q$ with respect to a dominating measures $\lambda$. Then, we can write

$$\left|\int f(dP - dQ)\right| = \left|\int f(p - q) d\lambda\right| \leq \left|\int f(\sqrt{p} + \sqrt{q})(\sqrt{p} - \sqrt{q}) d\lambda\right| \leq \sqrt{2 \int f^2(\sqrt{p} + \sqrt{q})^2 d\lambda d_H^2(P, Q)} \leq 2 \int f^2(p + q) d\lambda D_{KL}(P \parallel Q),$$

where (a) is justified by the non-negativity of the densities, (b) follows from the Cauchy-Schwarz inequality, (c) follows from (66), and (d) follows from (58).

Alternatively, we also have the upper bound

$$\left|\int f(dP - dQ)\right| \leq \left|\int f dP\right| + \left|\int f dQ\right|.$$
\[ \begin{align*}
&\leq \sqrt{\int f^2 dP} + \sqrt{\int f^2 dQ} \\
&\leq \sqrt{2 \int f^2 (dP + dQ)}, \quad (68)
\end{align*} \]

where (a) follows from the triangle inequality, (b) follows from Jensen’s inequality, and (c) follows from (59). Taking the minimum of (67) and (68) leads to the stated result.

**Lemma 32.** For any distribution \( P_{X,Y,Z} \) and \( p \geq 1 \),
\[
\mathbb{E}[|\text{Var}(X \mid Y) - \text{Var}(X \mid Z)|^p] \\
\leq 2^{2p+\frac{1}{2}} \sqrt{\mathbb{E}[|X|^4] \mathbb{E}[D_{KL}(P_{X,Y} \mid P_{X,Z})]}.
\]

**Proof:** Let \( P \) and \( Q \) be the random probability measures on \( \mathbb{R}^2 \) defined by
\[
P = P_{X,Y} \times P_{X,Y}, \\
Q = P_{X,Z} \times P_{X,Z},
\]
and let \( f : \mathbb{R}^2 \to \mathbb{R} \) be defined by \( f(x_1,x_2) = \frac{1}{2}(x_1 - x_2)^2 \). Then, by the variance decomposition (64), we can write
\[
\text{Var}(X \mid Y) = \int f dP, \quad \text{Var}(X \mid Z) = \int f dQ.
\]
Furthermore, by the upper bound \( f^2(x_1,x_2) \leq 2(x_1^2 + x_2^2) \), the expectation of the \( f^2 \) satisfies
\[
\int f^2 (dP + dQ) \leq 4 \mathbb{E}[X^4 \mid Y] + 4 \mathbb{E}[X^4 \mid Z]. \quad (69)
\]
Therefore, by Lemma 31, the difference between the conditional variances satisfies
\[
|\text{Var}(X \mid Y) - \text{Var}(X \mid Z)| \\
\leq \sqrt{2 \int f^2 (dP + dQ) \min\{D_{KL}(P \mid Q), 1\}} \\
\leq \sqrt{8 \mathbb{E}[X^4 \mid Y] + 8 \mathbb{E}[X^4 \mid Z] \min\{D_{KL}(P \mid Q), 1\}} \cdot (70)
\]
where the second inequality follows from (69).

The next step is to bound the expected \( p \)-th power of the right-hand side of (70). Starting with the Cauchy-Schwarz inequality, we have
\[
\mathbb{E}[|\text{Var}(X \mid Y) - \text{Var}(X \mid Z)|^p] \\
\leq \sqrt{\mathbb{E}[|8 \mathbb{E}[X^4 \mid Y] + 8 \mathbb{E}[X^4 \mid Z]|^p]} \\
\times \sqrt{\mathbb{E}[\min\{D_{KL}(P \mid Q), 1\}]^p}. \quad (71)
\]
For the first term on the right-hand side of (71), observe that, by Jensen’s inequality,
\[
\sqrt{\mathbb{E}[|8 \mathbb{E}[X^4 \mid Y] + 8 \mathbb{E}[X^4 \mid Z]|^p]} \leq \sqrt{8^p \mathbb{E}[X^{4p}] + 8^p \mathbb{E}[X^{4p}]} \\
= 2^p \sqrt{\mathbb{E}[X^{4p}]} \cdot (72)
\]
Meanwhile, the expectation in the second term on the right-hand side of (71) satisfies
\[
\mathbb{E}[\min\{D_{KL}(P \mid Q), 1\}]^p \leq \mathbb{E}[D_{KL}(P \mid Q)]^p = 2^p \mathbb{E}[D_{KL}(P_{X,Y} \mid P_{X,Z})], \quad (73)
\]
where the second step follows from the definition of \( P \) and \( Q \). Plugging (72) and (73) back into (71) leads to the stated result.

**Lemma 33.** For any distribution \( P_{X,Y,Z} \) and \( p \geq 1 \),
\[
\mathbb{E}[|\text{Cov}(X, Y \mid Z)|^p] \\
\leq 2^p \sqrt{\mathbb{E}[|X|^4 \mid Z] \mathbb{E}[|Y|^4 \mid Z]} I(X; Y \mid Z).
\]

**Proof:** Let \( P \) and \( Q \) be the random probability measures on \( \mathbb{R}^2 \) defined by
\[
P = P_{X,Y} \mid Z, \\
Q = P_{X,Z} \times P_{Y,Z},
\]
and let \( f : \mathbb{R}^2 \to \mathbb{R} \) be defined by \( f(x,y) = xy \). Then, the conditional covariance between \( X \) and \( Y \) can be expressed as
\[
\text{Cov}(X, Y \mid Z) = \int f(dP - dQ).
\]
Furthermore
\[
\int f^2 (dP + dQ) = \mathbb{E}[|XY|^2 \mid Z] + \mathbb{E}[X^2 \mid Z] \mathbb{E}[Y^2 \mid Z] \\
\leq 2 \sqrt{\mathbb{E}[X^4 \mid Z] \mathbb{E}[Y^4 \mid Z]},
\]
where the second step follows from the Cauchy-Schwarz inequality and Jensen’s inequality. Therefore, by Lemma 31, the magnitude of the covariance satisfies
\[
|\text{Cov}(X, Y \mid Z)| \\
\leq \sqrt{2 \int f^2 (dP + dQ) \min\{D_{KL}(P \mid Q), 1\}} \\
\leq 2 \mathbb{E}[|X^4 \mid Z] \mathbb{E}[Y^4 \mid Z] \min\{D_{KL}(P \mid Q), 1\}^{\frac{1}{2}}. \quad (74)
\]
The next step is to bound the expected \( p \)-th power of the right-hand side of (74). Starting with the Cauchy-Schwarz inequality, we have
\[
\mathbb{E}[|\text{Cov}(X, Y \mid Z)|^p] \leq 2^p \sqrt{\mathbb{E}[|X|^4 \mid Z] \mathbb{E}[Y^4 \mid Z]} \mathbb{E}[|\min\{D_{KL}(P \mid Q), 1\}|]^{\frac{p}{2}}. \quad (75)
\]
Note that the expectation in the second term on the right-hand side of (75) satisfies
\[
\mathbb{E}[\min\{D_{KL}(P \mid Q), 1\}]^p \leq \mathbb{E}[D_{KL}(P \mid Q)] = I(X; Y \mid Z), \quad (76)
\]
where the second step follows from the definition of \( P \) and \( Q \). Plugging (76) back into (75) leads to the stated result.

**Lemma 34.** For any distributions \( P_{X,Y} \) and \( P_{X,Z} \),
\[
|\text{mmse}(X \mid Y) - \text{mmse}(X \mid Z)| \\
\leq 2^\frac{1}{2} \sqrt{\mathbb{E}[|X|^4]} D_{KL}(P_{X,Y} \mid P_{X,Z}).
\]
Proof: Let $P$ and $Q$ be the distributions given by

$$P(x_1, x_2, y) = P_{X,Y}(x_1 | y) P_{X,Y}(x_2 | y) P_Y(y)$$

$$Q(x_1, x_2, y) = P_{X,Z}(x_1 | y) P_{X,Z}(x_2 | y) P_Z(y)$$

Then,

$$\text{mmse}(X | Y) = \frac{1}{2} \int (x_1 - x_2)^2 dP(x_1, x_2, y)$$

$$\text{mmse}(X | Z) = \frac{1}{2} \int (x_1 - x_2)^2 dQ(x_1, x_2, y)$$

and so, by Lemma 31,

$$|\text{mmse}(X | Y) - \text{mmse}(X | Z)|$$

$$\leq \frac{1}{2} \int (x_1 - x_2)^4 (dP(x_1, x_2, y) + dQ(x_1, x_2, y))$$

$$\times \sqrt{D_{KL}(P || Q)},$$

(77)

For the first term on the right-hand side of (77), observe that

$$\int (x_1 - x_2)^4 (dP(x_1, x_2, y) + dQ(x_1, x_2, y))$$

$$(a) \leq 8 \int (x_1^4 + x_2^4) (dP(x_1, x_2, y) + dQ(x_1, x_2, y))$$

$$\overset{(b)}{=} 32 \mathbb{E}[|X|^4],$$

(78)

where (a) follows from (60) and (b) follows from the fact that the marginal distributions of $X_1$ and $X_2$ are identical under $P$ and $Q$.

For the second term on the right-hand side of (77), observe that $P$ and $Q$ can be expressed as

$$P(x_1, x_2, y) = \frac{P_{X,Y}(x_1, y) P_{X,Y}(x_2, y)}{P_Y(y)}$$

$$Q(x_1, x_2, y) = \frac{P_{X,Z}(x_1, y) P_{X,Z}(x_2, y)}{P_Z(y)}.$$  

Letting $(X_1, X_2, Y) \sim P$, we see that the Kullback-Leibler divergence satisfies

$$D_{KL}(P || Q) = \mathbb{E} \left[ \log \left( \frac{P_{X,Y}(X_1, Y) P_{X,Y}(X_2, Y) P_Z(Y)}{P_{X,Y}(X_1, Y) P_{X,Z}(X_2, Y) P_Y(Y)} \right) \right]$$

$$= 2D_{KL}(P_{X,Y} || P_{X,Z}) - D_{KL}(P_Y || P_Z)$$

$$\leq 2D_{KL}(P_{X,Y} || P_{X,Z}).$$

(79)

Plugging (78) and (79) back into (77) completes the proof of Lemma 31.

\section*{Appendix B}

\section*{Proofs of Results in Section III}

\subsection*{A. Proof of Lemma 5}

Let $Y = \sqrt{\sigma} X + W$ where $X \sim P_X$ and $W \sim N(0,1)$ are independent. Letting $X_Y$ and $X_Y'$ denote conditionally independent draws from $P_{X|Y}$ the conditional variance can be expressed as $\text{Var}(X | Y) = \frac{1}{2} \mathbb{E} [(X_Y - X_Y')^2 | Y]$. Therefore,

$$\frac{d}{ds} \text{mmse}_X(s) \overset{(a)}{=} \mathbb{E} \left[ \text{Var}(X | Y)^2 \right]$$

$$\geq \frac{1}{4} \mathbb{E} \left[ \mathbb{E}[(X_Y - X_Y')^2 | Y]^2 \right]$$

where (a) follows from (11), (b) follows from Jensen’s inequality and (c) follows from (60) and the fact that $X_Y$ and $X_Y'$ have the same distribution as $X$. This completes the proof of (12).

Next, since $E[W | Y] = Y - \sqrt{\sigma} E[X | Y]$, the conditional variance can also be expressed as

$$\text{Var}(X | Y) = \frac{1}{s} \text{Var}(W | Y).$$

Using the same argument as above leads to

$$\frac{d}{ds} \text{mmse}_X(s) \leq \frac{4E[W^4]}{s^2} = \frac{12}{s^2}.$$  

This completes the proof of (13).

\subsection*{B. Proof of Lemma 6}

The first order MI difference can be decomposed as

$$I_{m,n} = h(Y_{m+1} | Y^m, A^{m+1}) - h(Y_{m+1} | Y^m, A^{m+1}, X^n),$$

where the differential entropies are guaranteed to exist because of the additive Gaussian noise. The second term is given by the entropy of the noise,

$$h(Y_{m+1} | Y^m, A^{m+1}, X^n) = h(W_{m+1}) = \frac{1}{2} \log(2\pi e),$$

and thus does not depend on $m$. Using this decomposition, we can now write

$$I_{m,n}'' = h(Y_{m+2} | Y^{m+1}, A^{m+2}) - h(Y_{m+1} | Y^m, A^{m+1})$$

$$= h(Y_{m+2} | Y^{m+1}, A^{m+2}) - h(Y_{m+2} | Y^m, A^{m+2})$$

$$= -I(Y_{m+1}; Y_{m+2} | Y^m, A^{m+2}),$$

where the second step follows from the fact that, conditioned on $(Y^m, A^m)$, the new measurements pairs $(Y_{m+1}, A_{m+1})$ and $(Y_{m+2}, A_{m+2})$ are identically distributed.

\subsection*{C. Proof of Lemma 7}

We first consider the upper bound in (17). Starting with the chain rule for mutual information, we have

$$I(X^n; Y^m | A^n) = \sum_{i=1}^{n} I(X_i; Y^m | A^n, X^{i-1}).$$

Next, observe that each summand satisfies

$$I(X_i; Y^m | A^n, X^{i-1})$$

$$\overset{(a)}{=} I(X_i; X^m_{i+1} | Y^m, X^{i-1})$$

$$\overset{(b)}{=} I(X_i; Y^m | A^n, X^{i-1}, X^m_{i+1}),$$

(81)

where (a) follows from the data processing inequality and (b) follows from expanding the mutual information using the chain rule and noting that $I(X_i; X^m_{i+1} | A^n, X^{i-1})$ is equal to zero because the signal entries are independent.
Conditioned on data \((A^m, X^{i-1}, X^{n}_{i+1})\), the mutual information provided by \(Y^m\) is equivalent to the mutual information provided by the measurement vector
\[
Y^m - \mathbb{E}[Y^m | A^m, X^{i-1}, X^{n}_{i+1}] = A^m(i)X_i + W^m,
\]
where \(A^m(i)\) is the \(i\)-th column of \(A^m\). Moreover, by the rotational invariance of the Gaussian distribution of the noise, the linear projection of this vector in the direction of \(A^m(i)\) contains all of the information about \(X_i\). This projection can be expressed as
\[
\frac{(A^m(i), A^m(i)X_i + W^m)}{\|A^m(i)\|} = \|A^m(i)\|X_i + W,
\]
where \(W = (A^m(i), W^m)/\|A^m(i)\|\) is Gaussian \(\mathcal{N}(0, 1)\) and independent of \(X_i\) and \(A^m(i)\) by the Gaussian distribution of \(W^m\). Therefore, the mutual information obeys
\[
I(X_i; Y^m | A^m, X^{i-1}, X^{n}_{i+1}) = I(X_i; \|A^m(i)\|X_i + W | \|A^m(i)\|) = \mathbb{E}[I_X(\|A^m(i)\|^2)] = \mathbb{E}[I_X(\frac{1}{n}\chi^2_m)],
\]
(82)
where the last step follows from the fact that the entries of \(A^m(i)\) are i.i.d. Gaussian \(\mathcal{N}(0, 1/n)\). Combining (80), (81), and (82) gives the upper bound in (17).

Along similar lines, the lower bound in (18) follows from
\[
M_{m,n} \triangleq \frac{1}{n} \text{mmse}(X^n | Y^m, A^m) \leq \text{mmse}(X^n | Y^m, A^m) \leq \text{mmse}(X^n | Y^m, A^m, X^{n-1}) \leq \text{mmse}(X^n | A^m(n)X_n + W^m, A^m(n)) \leq \text{mmse}(X^n | \|A^m(n)\|X_n + W, \|A^m(n)\|) \leq \mathbb{E}[\text{mmse}_X(\frac{1}{n}\chi^2_m)],
\]
where (a) follows from the fact that the distributions of the columns of \(A^m\) and entries of \(X^n\) are permutation invariant, (b) follows from the data processing inequality for MMSE, (c) follows from the independence of the signal entries, (d) follows from the Gaussian distribution of the noise \(W^m\), and (e) follows from the distribution of \(A^m(n)\).

We now turn our attention to the lower bound in (17). Let the QR decomposition of \(A^m\) be given by
\[
A^m = QR,
\]
where \(Q\) is an \(m \times n\) orthogonal matrix and \(R\) is an \(m \times n\) upper triangular matrix. Under the assumed Gaussian distribution on \(A^m\), the nonzero entries of \(R\) are independent random variables with \cite{45} Theorem 2.3.18:
\[
R_{i,j} \sim \begin{cases} \frac{1}{n} \chi^2_{m-i+1}, & \text{if } i = j \\ \mathcal{N}(0, \frac{1}{n}), & \text{if } i < j. \end{cases}
\]
Let the rotated measurements and noise be defined by
\[
\tilde{Y}^m = Q^T Y^m, \quad \tilde{W}^m = Q^T W^m
\]
and observe that
\[
\tilde{Y}^m = RX^n + \tilde{W}^m.
\]
By the rotational invariance of the Gaussian distribution of the noise \(W^m\), the rotated noise \(\tilde{W}^m\) is Gaussian \(\mathcal{N}(0, I_{m \times m})\) and independent of everything else. Therefore, only the first \(d \triangleq \min(m, n)\) measurements provide any information about the signal. Using this notation, the mutual information can be expressed equivalently as
\[
I(X^n, \tilde{Y}^d | A^m) = I(X^n, \tilde{Y}^d | R) = \sum_{i=1}^{d} I(X^n; \tilde{Y}_k | \tilde{Y}^d_{k+1}, R),
\]
(84)
where the second step follows from the chain rule for mutual information.

To proceed, note that the measurements \(\tilde{Y}^d_k\) are independent of the first part of the signal \(X^{k-1}\), because \(R\) is upper triangular. Therefore, for all \(1 \leq k \leq d\),
\[
I(X^n; \tilde{Y}_k | \tilde{Y}^d_{k+1}, R) \geq I(X_k; \tilde{Y}_k | \tilde{Y}^d_{k+1}, X^n_{k+1}, R)
\]
(85)
where (a) follows from the data processing inequality, (b) follows from the fact that \(R\) is upper triangular and the independence of the signal entries, and (c) follows from (83). Combining (84) and (85) gives the upper bound in (17). For the upper bound in (18), suppose that \(m \geq n\) and let \(\tilde{Y}^n\) be the rotated measurements defined above. Then we have
\[
M_{m,n} \triangleq \frac{1}{n} \text{mmse}(X^n | Y^m, A^m) \leq \text{mmse}(X^n | Y^m, A^m) \leq \text{mmse}(X^n | Y^m, R) \leq \text{mmse}(X^n | \tilde{Y}^n, R_{n,n}) \leq \text{mmse}(X^n | R_{n,n}X_n + \tilde{W}^n, R_{n,n}) \leq \mathbb{E}[\text{mmse}_X(\frac{1}{n}\chi^2_{m-n+1})],
\]
(83)
where (a) follows from the fact that the distributions of the columns of \(A^m\) and entries of \(X^n\) are permutation invariant, (b) follows from the fact that multiplication by \(Q\) is a one-to-one transformation, (c) follows from the data processing inequality for MMSE, (d) follows from the fact that \(R\) is upper triangular with \(m \geq n\), and (e) follows from (83).

\[D. \text{ Proof of Lemma 8}\]

Let \(U = \frac{1}{n} \chi^2_{n-m+1}\) and \(V = \frac{1}{n} \chi^2_{m+1}\) be independent scaled chi-square random variables and let \(Z = U + V\). Using this notation, the lower bound in (17) satisfies
\[
\frac{1}{n} \sum_{k=1}^{n} \mathbb{E}[I_X(\frac{1}{n}\chi^2_{m-k+1})] \geq \mathbb{E}[I_X(U)],
\]
(86)
where we have used the fact that the mutual information function is non-decreasing. Moreover, by (10), we have
\[ \mathbb{E}[I_X(Z)] - \mathbb{E}[I_X(U)] \leq \frac{1}{2} \mathbb{E}[\{Z/U - 1\}_+] \]
\[ = \frac{1}{2} \mathbb{E}[V/U] \]
\[ = \frac{1}{2} \frac{n + 1}{m - n - 1}. \quad (87) \]

Next, observe that \( Z \) has a scaled chi-squared distribution \( Z \sim \frac{1}{n} \chi^2_{m+2} \), whose inverse moments are given by
\[ \mathbb{E}[Z^{-1}] = \frac{n}{m}, \quad \text{Var}(Z^{-1}) = \frac{2n^2}{m^2(m - 2)}. \]
Therefore, by (10), we have
\[ I_X \left( \frac{m}{m} \right) - \mathbb{E}[I_X(Z)] \leq \frac{1}{2} \mathbb{E} \left[ \left( \frac{m/n}{Z} - 1 \right)_+ \right] \]
\[ \leq \frac{m}{2n} \mathbb{E} \left[ \frac{1}{Z} - \frac{n}{m} \right] \]
\[ \leq \frac{m}{2n} \sqrt{\text{Var}(Z^{-1})} \]
\[ = \frac{1}{2} \sqrt{\frac{2}{m - 2}}. \quad (88) \]
where the second and third steps follow from Jensen’s inequality. Combining (86), (87) and (88) completes the proof of Inequality (19).

We use a similar approach for the MMSE. Note that
\[ \mathbb{E}[	ext{mmse}_X(U)] = \mathbb{E}[	ext{mmse}_X \left( \frac{1}{n} \chi^2_{m-n+1} \right)] \]
\[ \mathbb{E}[	ext{mmse}_X(Z)] \leq \mathbb{E}[	ext{mmse}_X \left( \frac{1}{n} \chi^2_m \right)], \quad (89) \]
where the second inequality follows from the monotonicity of the MMSE function. By Lemma 5, the MMSE obeys
\[ \mathbb{E}[	ext{mmse}_X(U)] - \mathbb{E}[	ext{mmse}_X(Z)] \leq 12 \mathbb{E} \left[ \frac{1}{U - Z} \right] \]
\[ = 12 \left( \mathbb{E}[U^{-1}] - \mathbb{E}[Z^{-1}] \right) \]
\[ = 12 \frac{n + 1}{m - n - 1}. \quad (90) \]
Moreover,
\[ \mathbb{E}[	ext{mmse}_X(Z)] - \text{mmse}_X \left( \frac{m}{m} \right) \leq 12 \mathbb{E} \left[ \frac{1}{Z} - \frac{n}{m} \right] \]
\[ \leq 12 \sqrt{\text{Var}(Z^{-1})} \]
\[ = \frac{1}{2} \sqrt{\frac{2}{m - 2}}. \quad (91) \]
where the second and third steps follow from Jensen’s inequality. Combining (89), (90) and (91) completes the proof of Inequality (20).

E. Proof of Lemma 9

The upper bound in (22) follows from noting that
\[ \mathcal{I}_{\text{RS}}(\delta) \triangleq \min_{\delta \geq 0} R(\delta, z) \leq R(\delta, 0) = I_X(\delta). \]
For the lower bound, observe that the replica-MI function can also be expressed in terms of the replica-MMSE function as
\[ \mathcal{I}_{\text{RS}}(\delta) = R(\delta, \mathcal{M}_{\text{RS}}(\delta)). \]
Since the term \( \log(1 + z) - \frac{z}{1 + z} \) in the definition of \( R(\delta, z) \) is non-negative, we have the lower bound
\[ \mathcal{I}_{\text{RS}}(\delta) \geq I_X \left( \frac{\delta}{1 + \mathcal{M}_{\text{RS}}(\delta)} \right). \quad (92) \]
Next, we recall that the replica-MMSE function satisfies the fixed-point equation
\[ \mathcal{M}_{\text{RS}}(\delta) = \text{mmse}_X \left( \frac{\delta}{1 + \mathcal{M}_{\text{RS}}(\delta)} \right). \quad (93) \]
Also, for any signal distribution \( P_X \) with, the MMSE function satisfies the upper bound \( \text{mmse}_X(s) \leq 1/s \) [30 Proposition 4]. Therefore,
\[ \mathcal{M}_{\text{RS}}(\delta) \leq \frac{1 + \mathcal{M}_{\text{RS}}(\delta)}{\delta}. \]
For \( \delta > 1 \), rearranging the terms leads to the upper bound
\[ \mathcal{M}_{\text{RS}}(\delta) \leq \frac{1}{\delta - 1}. \quad (94) \]
Combining (92) and (94) with the fact that the mutual information is non-decreasing yields
\[ \mathcal{I}_{\text{RS}}(\delta) \geq I_X \left( \frac{\delta}{1 + \frac{1}{\delta - 1}} \right) = I_X(\delta - 1). \]
Lastly, we consider the bounds in (23). Combining (92) and (94) with the fact that the MMSE is non-increasing yields
\[ \mathcal{M}_{\text{RS}}(\delta) \leq \text{mmse}_X \left( \frac{\delta}{1 + \frac{1}{\delta - 1}} \right) = \text{mmse}_X(\delta - 1). \]
Alternatively, starting with (93) and using the non-negativity of \( \mathcal{M}_{\text{RS}} \) leads to the lower bound. This completes the proof of Lemma 9.

F. Proof of Lemma 10

To lighten notation, we will write \( I(A) \) in place of \( I_{m,n}(A^m) \). By the Gaussian Poincaré inequality [43, Theorem 3.20], the variance satisfies
\[ \text{Var}(\mathbb{E}[I(A)]) \leq \mathbb{E} \left[ \| \nabla_A I(A) \|^2_F \right], \quad (95) \]
where \( \nabla_A \) is the gradient operator with respect to \( A \). Furthermore, by the multivariate I-MMSE relationship [46, Theorem 1], the gradient of the mutual information with respect to \( A \) is given by
\[ \nabla_A I(A) = \mathcal{K}(A), \quad (96) \]
where \( \mathcal{K}(A) = \mathbb{E}[\text{Cov}(X^n|Y^m, A) | A] \) is the expected posterior covariance matrix as a function of the matrix \( A \).
Next, we recall some basic facts about matrices that will allow us to bound the magnitude of the gradient. For symmetric matrices \( U \) and \( V \) the notation \( U \preceq V \) mean that \( V - U \) is
positive semidefinite. If $U$ and $V$ are positive definite with $U \preceq V$ then $U^2 \preceq V^2$, by [47] Theorem 7.7.3, and thus
\[
\|SU\|_F^2 = \text{tr}(SU^2S^T) \leq \text{tr}(SV^2S^T)
\]
for every matrix $S$.

Since the since the conditional expectation minimizes the squared error, the expected covariance matrix can be upper bounded in terms of the MSE matrix associated with the optimal linear estimator:
\[
K(A) \leq (I_{n \times n} + \text{Var}(X)A^T A^T)^{-1} \text{Var}(X).
\]
Combining this inequality with the arguments given above and the fact that $(I_{n \times n} + \text{Var}(X)A^T A^T)^{-1} \preceq I_{n \times n}$ leads to
\[
\|AK(A)\|_F^2 \leq \text{tr}((A^T A)^{-1}).
\]
(97)

Alternatively, for $m > n$, the matrix $A^T A$ is full rank with probability one and thus $K(A) \preceq (A^T A)^{-1}$ with probability one. This leads to the upper bound
\[
\|AK(A)\|_F^2 \leq \text{tr}((A^T A)^{-1}).
\]
(98)

To conclude, note that under the assumed Gaussian distribution on $A$,
\[
\mathbb{E}[\text{tr}(AA^T)] = m
\]
\[
\mathbb{E}[\text{tr}((A^T A)^{-1})] = \frac{n^2}{(m-n-1)_+},
\]
where the second expression follows from [45] Theorem 3.3.16.

Combining these expectations with (95) and (96) and the upper bounds (97) and (98) completes the proof.

**G. Proof of Lemma 11**

To simplify notation, the mutual information density is denoted by $Z = i(X^n; Y^m | A^m)$. Note that $Z$ can be expressed as a function of the random tuple $(X^n, W^m, A^m)$ according to
\[
Z = \log \left( \frac{f_{Y^m|X^n,A^m}(A^m X^n + W^m | X^n, A^m)}{f_{Y^m|A^m}(A^m X^n + W^m | A^m)} \right).
\]
(99)

Starting with the law of total variance [65], we see that
\[
\text{Var}(Z) = \mathbb{E}[\text{Var}(Z | A^m)] + \text{Var}(\mathbb{E}[Z | A^m]).
\]
(100)
The second term on the right-hand side of (100) is variance with respect to the matrix, which is bounded by Lemma 10.

The first term on the right-hand side of (100) is the variance with respect to the signal and the noise. Since the entries of $X^n$ and $W^m$ are independent, the variance can be bounded using the the Efron-Stein inequality [43] Theorem 3.1.1, which yields
\[
\mathbb{E}[\text{Var}(Z | A^m)] \leq \sum_{i=1}^{n} \mathbb{E}\left[ (Z - \mathbb{E}_X[Z])^2 \right] + \sum_{i=1}^{m} \mathbb{E}\left[ (Z - \mathbb{E}_W[Z])^2 \right].
\]
(101)

At this point, Lemma 11 follows from combining (100), Lemma 10 and (101) with the following inequalities
\[
\mathbb{E}\left[ (Z - \mathbb{E}_X[Z])^2 \right] \leq 12 \left( 1 + \left( \frac{\sqrt{2}}{\mathcal{B}} \right) B^2 \right)
\]
\[
\mathbb{E}\left[ (Z - \mathbb{E}_W[Z])^2 \right] \leq \sqrt{B}.
\]
(102)
(103)

Inequalities (102) and (103) are proved in the following subsections.

1) **Proof of Inequality (102)**: Observe that the expectation $\mathbb{E}\left[ (Z - \mathbb{E}_{X}[Z])^2 \right]$ is identical for all $i \in [n]$ because the distribution on the entries in $X^n$ and the columns of $A^m$ are permutation invariant. Throughout this proof, we focus on the variance with respect to the last signal entry $X_n$.

Starting with the chain rule for mutual information density, we obtain the decomposition
\[
Z = i(X_n; Y^m | A^m) + i(X_n^{-1}; Y^m | X_n, A^m).
\]
(104)
The second term is independent of $X_n$, and thus does not contribute to the conditional variance. To characterize the first term, we introduce a transformation of the data that isolates the effect of the $n$th signal entry. Let $Q$ be drawn uniformly from the set of $m \times m$ orthogonal matrices whose last row is the unit vector in the direction of the last column of $A^m$, and let the rotated data be defined according to
\[
\hat{Y}^m = QY^m, \quad \hat{A}^m = QA^m, \quad \hat{W}^m = QW^m.
\]
By construction, the last column of $\hat{A}^m$ is zero everywhere except for the last entry with
\[
\hat{a}_{i,n} = \begin{cases} 
0, & \text{if } 1 \leq i \leq m - 1 \\
\|A^m(n)\|, & \text{if } i = m,
\end{cases}
\]
where $A^m(n)$ denotes the $n$-th column of $A^m$. Furthermore, by the rotational invariance of the Gaussian distribution of the noise, the rotated noise $\hat{W}^m$ has the same distribution as $W^m$ and is independent of everything else.

Expressing the mutual information density in terms of the rotated data leads to the further decomposition
\[
i(X_n; Y^m | A^m) \overset{(a)}{=} i(X_n; \hat{Y}^m | \hat{A}^m)
\]
\[
\overset{(b)}{=} i(X_n; \hat{Y}^m | \hat{Y}^{m-1}, \hat{A}^m)
\]
\[
+ i(X_n; \hat{Y}^{m-1} | \hat{A}^m)
\]
\[
\overset{(c)}{=} i(X_n; \hat{Y}^m | \hat{Y}^{m-1}, \hat{A}^m),
\]
(105)
where (a) follows from fact that multiplication by $Q$ is a one-to-one transformation, (b) follows from the chain rule for mutual information density, and (c) follows from fact that the first $m - 1$ entries of $\hat{Y}^m$ are independent of $X_n$.

To proceed, we introduce the notation $U = (\hat{Y}^{m-1}, \hat{A}^m)$. Since the noise is independent of the measurements, the conditional density of $\hat{Y}^m$ given $(X^n, U, \hat{A}^m)$ obeys
\[
\hat{f}_{\hat{Y}^m|X^n,U,\hat{A}^m}(\hat{y}^m | x^n, u, \hat{a}_m)
\]
\[
= \hat{f}_{\hat{Y}^m}(\hat{y}^m - (\hat{a}_m, x^n))
\]
\[
= \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{1}{2} (\hat{y}^m - (\hat{a}_m, x^n))^2 \right).
\]
Starting with (105), the mutual information density can now be expressed as
\[
i(X_n; Y_n^m | A^m) = i \left( X_n; Y_m | U, \tilde{A}_m \right)
= \log \left( \frac{f_{\tilde{Y}_m|X_n^m, U, \tilde{A}_m}(Y_m | X_n^m, U, \tilde{A}_m)}{f_{\tilde{Y}_m|U, \tilde{A}_m}(Y_m | U, \tilde{A}_m)} \right),
= g(U, Y_m, \tilde{A}_m) - \frac{1}{2} \tilde{W}_m^2,
\]
(106)
where
\[
g(U, Y_m, \tilde{A}_m) = \log \left( \frac{(2\pi)^{-\frac{d}{2}}}{f_{\tilde{Y}_m|U, \tilde{A}_m}(Y_m | U, \tilde{A}_m)} \right).
\]
Furthermore, by (104) and (106), the difference between Z and its conditional expectation with respect to X_n is given by
\[
Z - \mathbb{E}_{X_n}[Z] = g(U, Y_m, \tilde{A}_m) - \mathbb{E}_{X_n} \left[ g(U, Y_m, \tilde{A}_m) \right].
\]
Squaring both sides and taking the expectation yields
\[
\mathbb{E} \left[ (Z - \mathbb{E}_{X_n}[Z])^2 \right]
= \mathbb{E} \left[ \left( g(U, Y_m, \tilde{A}_m) - \mathbb{E}_{X_n} \left[ g(U, Y_m, \tilde{A}_m) \right] \right)^2 \right]
\leq (b) \mathbb{E} \left[ g^2(U, Y_m, \tilde{A}_m) \right],
\]
(107)
where (b) follows from the law of total variance (65).
Next, we bound the function g(u, y_m, \tilde{a}_m). Let X_n^m be drawn according to the conditional distribution \( P_{X_n|U=u} \). Then, the conditional density of \( Y_m \) given \( (U, \tilde{A}_m) \) is given by
\[
f_{Y_m|U, \tilde{A}_m}(y_m | u, \tilde{a}_m)
= \mathbb{E} \left[ f_{Y_m|X_n^m, U, \tilde{A}_m}(y_m | X_n^m, u, \tilde{a}_m) \right]
= \mathbb{E} \left[ \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{1}{2} (y_m - \langle a_m, X_n^m \rangle)^2 \right) \right].
\]
Since the conditional density obeys the upper bound
\[
f_{Y_m|U, \tilde{A}_m}(y_m | u, \tilde{a}_m) \leq (2\pi)^{-\frac{d}{2}},
\]
we see that g(u, y_m, \tilde{a}_m) is nonnegative. Alternatively, by Jensen’s inequality,
\[
f_{Y_m|U, \tilde{A}_m}(y_m | u, \tilde{a}_m)
\geq \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{1}{2} \mathbb{E} [ (y_m - \langle a_m, X_n^m \rangle)^2 ] \right),
\]
and thus
\[
g(u, y_m, \tilde{a}_m) \leq \frac{1}{2} \mathbb{E} \left[ (y_m - \langle a_m, X_n^m \rangle)^2 \right].
\]
Using these facts leads to the following inequality:
\[
g^2(u, y_m, \tilde{a}_m)
\leq \frac{1}{4} \left( \mathbb{E}_{X_n^m} \left[ (y_m - \langle a_m, X_n^m \rangle)^2 \right]\right)^2
\leq \frac{1}{4} \mathbb{E}_{X_n^m} \left[ (y_m - \langle a_m, X_n^m \rangle)^4 \right]
\leq 2(y_m)^4 + 2\mathbb{E}_{X_n^m} \left[ (\langle a_m, X_n^m \rangle)^4 \right],
\]
where (a) follows from Jensen’s inequality and (b) follows from (60). Taking the expectation with respect to the random tuple (U, Y_m, \tilde{A}_m), we can now write
\[
\mathbb{E} \left[ g^2(U, Y_m, \tilde{A}_m) \right] \leq 2\mathbb{E} \left[ (Y_m)^4 \right] + 2\mathbb{E} \left[ (\langle A_m, X_n^0 \rangle)^4 \right]
\leq 2\mathbb{E} \left[ (Y_m)^4 \right] + 2\mathbb{E} \left[ (\langle A_m, X_n^0 \rangle)^4 \right],
\]
(108)
where (a) follows from the fact that X_n^0 has the same distribution as X_n and is independent of A_m. To upper bound the first term, observe that
\[
\mathbb{E} \left[ (Y_m)^4 \right] \leq \mathbb{E} \left[ (\tilde{W}_m + \sum_{i=1}^{n} \tilde{A}_{m,i} X_i)^4 \right]
\leq (a) \left( \mathbb{E} \left[ \tilde{W}_m^4 \right] \right)^{\frac{1}{4}} + \left( \mathbb{E} \left[ (\langle A_m, X_n^0 \rangle)^4 \right] \right)^{\frac{1}{4}}
= \left( 3^{\frac{4}{4}} + \left( \mathbb{E} \left[ (\langle A_m, X_n^0 \rangle)^4 \right] \right)^{\frac{1}{4}} \right)^4
\]
(109)
where (a) follows from Minkowski’s inequality (61). To bound the fourth moment of (A_m, X_n^0), we use the fact that the entries of the rotated measurement vector A_m are independent with
\[
\tilde{A}_{m,i} \sim \mathcal{N}(0, \frac{1}{n}), \quad \text{if } i \leq n - 1
\]
\[
\text{and } \tilde{A}_{m,i} \sim \frac{1}{\sqrt{n}} \chi_m, \quad \text{if } i = n,
\]
where \( \chi_m \) denotes a chi random variable with m degrees of freedom. Thus, we have
\[
\mathbb{E} \left[ (\langle A_m, X_n^0 \rangle)^4 \right]\]
\leq \left( \mathbb{E} \left[ \sum_{i=1}^{n-1} \tilde{A}_{m,i} X_i \right] \right)^{\frac{4}{4}} + \left( \mathbb{E} \left[ (\langle A_m, X_n^0 \rangle)^4 \right] \right)^{\frac{1}{4}}
\leq \left( \frac{3(n-1)^2}{n^4} + \frac{(m(m+2)}{n^4} \mathbb{E} \left[ X_1^4 \right] \right)\]
\leq \left( 1 + \frac{m}{n} \right) (3B)^4,
\]
(110)
where (a) follows from Minkowski’s inequality (61), (b) follows from the distribution on \( A^m \) and (c) follows from Assumption 2 and inequality (58) applied to \( \|X_n^0\|^4 = \left( \sum_{i=1}^{n-1} X_i^2 \right)^2 \).
Finally, combining (107), (108), (109), and (110) leads to
\[
\mathbb{E} \left[ (Z - \mathbb{E}_{X_n}[Z])^2 \right] \leq 2 \left( 3^{\frac{1}{4}} + \left[ 1 + \sqrt{\frac{m}{n}} \right] (3B)^{\frac{1}{4}} \right)^4
+ 2 \left( 1 + \sqrt{\frac{m}{n}} \right) (3B)^{\frac{1}{4}}
\leq 12 \left( 1 + \left[ 1 + \sqrt{\frac{m}{n}} \right] B^{\frac{1}{4}} \right)^4.
\]
This completes the proof of Inequality (102).
2) Proof of Inequality (103): Observe that the expectation $\mathbb{E}\left[(Z_k - \mathbb{E}_{W_m}(Z_k))^2\right]$ is identical for all $k \in [m]$ because the distributions on the entries in $W^m$ and the rows of $A^m$ are permutation invariant. Throughout this proof, we focus on the variance with respect to the last noise entry $W_m$.

Recall from (99), $Z$ can be expressed as a function of $(X^n, W^m, A^m)$. By the Gaussian Poincaré inequality [43, Theorem 3.20], the variance with respect to $W_m$ obeys

$$\mathbb{E}\left[(Z - \mathbb{E}_{W_m}(Z))^2\right] \leq \mathbb{E}\left[\left(\frac{\partial}{\partial W_m} Z\right)^2\right], (111)$$

where $\frac{\partial}{\partial W_m} Z$ denotes the partial derivative of the right-hand side of (99) evaluated at the point $(X^n, W^m, A^m)$.

To compute the partial derivative, observe that by the chain rule for mutual information density,

$$Z = \iota(X^n; Y^{m-1} | A^m) + \iota(X^n; Y_m | Y^{m-1}, A^m).$$

In this decomposition, the first term on the right-hand side is independent of $W_m$. The second term can be decomposed as

$$\iota(X^n; Y_m | Y^{m-1}, A^m)$$

where the second inequality follows from Jensen’s inequality (58). (b) follows from (50), and (c) follows from Jensen’s inequality. Taking the expectation of both sides leads to

$$\mathbb{E}\left[|\mathcal{E}_{m,n}|^2\right] \leq \frac{16}{n} \sum_{i=1}^{n} \mathbb{E}\left[|X_i|^4\right] \leq 16B,$$

where the second inequality follows from Assumption 2.

Next, observe that the conditional distribution $Y_{m+1}$ given $X^n$ is zero-mean Gaussian with variance $1 + \frac{1}{n} \|X^n\|^2$. Thus,

$$\mathbb{E}[Y_{m+1}^4] = \mathbb{E}[Y^4 | X^n] = 3\mathbb{E}\left[(1 + \frac{1}{n} \|X^n\|^2)^2\right] \leq 6 \left(1 + \frac{1}{n^2} \|X^n\|^4\right) \leq 6(1 + B),$$

where (a) follows from (59) and (b) follows from (58) and Assumption 2. Along similar lines,

$$\mathbb{E}\left[|Y_{m+1} - \mathbb{E}[Y_{m+1} | Y^n, A^{m+1}]|^4\right] \leq 16 \mathbb{E}\left[Y_{m+1}^4\right] \leq 96(1 + B),$$

where (a) follows from (60) and (b) follows from Jensen’s inequality.

Finally, we note that the proof of (27) can be found in the proof of Lemma 20.
B. Proof of Lemma \[ \text{[13]} \]

The starting point for these identities is to observe that the differences between the measurements \( Y_i \) and \( Y_j \) and their conditional expectations given the data \((Y^m, A^m, A_i, A_j)\) can be expressed as

\[
\begin{bmatrix}
Y_i - \hat{Y}_i \\
Y_j - \hat{Y}_j
\end{bmatrix} = \begin{bmatrix}
A_i^T & A_j^T
\end{bmatrix} \begin{bmatrix}
X^n - \hat{X}^n
\end{bmatrix} + \begin{bmatrix}
W_i \\
W_j
\end{bmatrix},
\]

(113)

where \( \hat{X}^n = \mathbb{E}[X^n | Y^m, A^m] \) is the signal estimate after the first \( m \) measurements.

1) **Proof of Identity \[ \text{[13]} \]:** Starting with (113), we see that the conditional variance of \( Y_j \) can be expressed in terms of the posterior covariance matrix of the signal:

\[
\text{Var}(Y_i | Y^m, A^m, A_i) = A_i^T \text{Cov}(X^n | Y^m, A^m) A_i + 1.
\]

Taking the expectation of both sides with respect to \( A_i \) yields

\[
\mathbb{E}_{A_i} \left[ \text{Var}(Y_i | Y^m, A^m, A_i) \right] = \mathbb{E}_{A_i} \left[ A_i^T \text{Cov}(X^n | Y^m, A^m) A_i \right] + 1
\]

\[
= \mathbb{E}_{A_i} \left[ \text{tr} \left( A_i A_i^T \text{Cov}(X^n | Y^m, A^m) \right) \right] + 1
\]

\[
= \mathbb{E}_{A_i} \left[ \text{tr} \left( A_i A_i^T \text{Cov}(X^n | Y^m, A^m) \right) \right] + 1
\]

\[
= \frac{1}{n} \text{tr} \left( \text{Cov}(X^n | Y^m, A^m) \right) + 1,
\]

where we have used the fact that \( \mathbb{E}[A_i A_i^T] = \frac{1}{2} I_m \times m \).

2) **Proof of Identity \[ \text{[31]} \]:** Along the same lines as the conditional variance, we see that the conditional covariance between \( Y_i \) and \( Y_j \) is given by

\[
\text{Cov}(Y_i, Y_j | Y^m, A^m, A_i, A_j) = A_i^T \text{Cov}(X^n | Y^m, A^m) A_i.
\]

Letting \( K = \text{Cov}(X^n | Y^m, A^m) \), the expectation of the squared covariance with respect to \( A_i \) and \( A_j \) can be computed as follows:

\[
\mathbb{E}_{A_i, A_j} \left[ (\text{Cov}(Y_i, Y_j | Y^m, A^m, A_i, A_j))^2 \right]
\]

\[
= \mathbb{E}_{A_i, A_j} \left[ (A_i^T K A_j) (A_j^T K A_i) \right]
\]

\[
= \frac{1}{n} \mathbb{E}_{A_i, A_j} \left[ A_i^T K^2 A_i \right]
\]

\[
= \frac{1}{n} \mathbb{E}_{A_i, A_j} \left[ \text{tr} (A_i A_i^T K^2) \right]
\]

\[
= \frac{1}{n} \text{tr} \left( \mathbb{E}_{A_i, A_j} [A_i A_i^T] K^2 \right)
\]

\[
= \frac{1}{n^2} \text{tr} (K^2),
\]

where we have used the fact that \( A_i \) and \( A_j \) are independent with \( \mathbb{E}[A_i A_i^T] = \frac{1}{2} I_m \times m \). Noting that \( \text{tr}(K^2) = ||K||_F^2 \), completes the proof of Identity \[ \text{[31]} \].

3) **Proof of Identity \[ \text{[32]} \]:** For this identity, observe that the measurement vectors \((A_i, A_j)\) and the noise terms \((W_i, W_j)\) in (113) are Gaussian and independent of the signal error. Therefore, the conditional distribution of \((Y_i - \hat{Y}_i, Y_j - \hat{Y}_j)\) given \((X^n, Y^m, A^m)\) is i.i.d. Gaussian with mean zero and covariance

\[
\text{Cov} \left( \begin{bmatrix}
Y_i - \hat{Y}_i \\
Y_j - \hat{Y}_j
\end{bmatrix} | X^n, Y^m, A^m \right) = \begin{bmatrix}
1 + \mathcal{E}_m & 0 \\
0 & 1 + \mathcal{E}_m
\end{bmatrix}.
\]

Using the fact that the expected absolute value of standard Gaussian variable is equal to \( \sqrt{2/\pi} \), we see that the conditional absolute moments are given by

\[
\mathbb{E} \left[ |Y_i - \hat{Y}_i| | X^n, Y^m, A^m \right] = \sqrt{\frac{2}{\pi}} \sqrt{1 + \mathcal{E}_m}
\]

\[
\mathbb{E} \left[ |Y_i - \hat{Y}_i||Y_j - \hat{Y}_j| | X^n, Y^m, A^m \right] = \frac{2}{\pi} (1 + \mathcal{E}_m).
\]

Taking the expectation of both sides with respect to the posterior distribution of \( X^n \) given \((Y^m, A^m)\) leads to

\[
\mathbb{E} \left[ |Y_i - \hat{Y}_i| | Y^m, A^m \right] = \sqrt{\frac{2}{\pi}} \mathbb{E} \left[ \sqrt{1 + \mathcal{E}_m} | Y^m, A^m \right]
\]

\[
\mathbb{E} \left[ |Y_i - \hat{Y}_i||Y_j - \hat{Y}_j| | Y^m, A^m \right] = \frac{2}{\pi} (1 + V_m).
\]

Finally, we see that the conditional covariance is given by

\[
\text{Cov} \left( \begin{bmatrix}
Y_i - \hat{Y}_i \\
Y_j - \hat{Y}_j
\end{bmatrix} | Y^m, A^m \right)
\]

\[
= \frac{2}{\pi} \left( \mathbb{E} \left[ \sqrt{1 + \mathcal{E}_m} | Y^m, A^m \right] \right)^2
\]

\[
= \frac{2}{\pi} \mathbb{E} \left[ \sqrt{1 + \mathcal{E}_m} | Y^m, A^m \right].
\]

This completes the proof of identity \[ \text{[32]} \].

C. Proof of Lemma \[ \text{[74]} \]

To simplify notation, we drop the explicit dependence on the problem dimensions and write \( \mathcal{E} \) and \( V \) instead of \( \mathcal{E}_{m,n} \) and \( V_{n,m} \). Also, we use \( U = (Y^m, A^m) \) to denote the first \( m \) measurements. Using this notation, the posterior distribution is given by \( P_{X^n|U} \) and the posterior variance is \( V = \mathbb{E}[\mathcal{E} | U] \).

1) **Proof of Inequality \[ \text{[33]} \]:** To begin, let \( \mathcal{E}' \) be a conditionally independent copy of \( \mathcal{E} \) that is drawn according to the posterior distribution \( P_{\mathcal{E}|U} \). Starting with the fact that the posterior variance can expressed as \( V = \mathbb{E}[\mathcal{E}' | U] \), the absolute deviation between \( \mathcal{E} \) and \( V \) can be upper bounded using the following series of inequalities:

\[
\mathbb{E}[|\mathcal{E} - V|] = \mathbb{E}_U \left[ \mathbb{E}[|\mathcal{E} - \mathcal{E}'| | U] \right] \leq \mathbb{E}_U \left[ \mathbb{E}[|\mathcal{E} - \mathcal{E}'| | U] \right] = \mathbb{E}[|\mathcal{E} - \mathcal{E}'|]
\]

\[
= \mathbb{E} \left[ \left( \sqrt{1 + \mathcal{E}} + \sqrt{\mathcal{E} + \mathcal{E}'} \right) \times \left( \sqrt{1 + \mathcal{E}' - \sqrt{1 + \mathcal{E}'} \right) \right]
\]

\[
\leq \sqrt{\mathbb{E} \left[ \left( \sqrt{1 + \mathcal{E}} + \sqrt{\mathcal{E} + \mathcal{E}'} \right)^2 \right]} \times \sqrt{\mathbb{E} \left[ \left( \sqrt{1 + \mathcal{E}' - \sqrt{1 + \mathcal{E}'} \right)^2 \right]},
\]

(114)

where (a) follows from Jensen’s inequality and the fact that \( \mathcal{E} \) and \( \mathcal{E}' \) are conditionally independent given \( U \) and (b) follows from the Cauchy-Schwarz inequality.
For the first term on the right-hand side of (114), observe that
\[
\mathbb{E} \left[ \sqrt{1 + \mathcal{E} + \sqrt{1 + \mathcal{E}^2}} \right]^2 \leq 2\mathbb{E}[(1 + \mathcal{E})] + 2\mathbb{E}[(1 + \mathcal{E}^2)]
\]
where (a) follows from the Cauchy-Schwarz inequality and (b) follows from the fact that \( \mathcal{E} \) and \( \mathcal{E}' \) are identically distributed.

For the second term on the right-hand side of (114), observe that
\[
\mathbb{E} \left[ \sqrt{1 + \mathcal{E} - \sqrt{1 + \mathcal{E}^2}} \right] = 4(1 + M_{m,n}) \leq C_B,
\]
where (a) follows from (59) and (b) follows from the fact that, for each realization \( U = u \), we have
\[
\mathbb{E}[\mathcal{E} | U = u] = \sqrt{2} \mathbb{E}[\mathcal{E}^2 | U = u] \leq C_B.
\]

Thus, in order to complete the proof, we need to show that the mutual information difference density can be decomposed into the conditional variance decomposition (64) and (b) follows from the conditional variance decomposition (64).

To bound the expected covariance, we apply Lemma 33 with \( p = 2 \) to obtain
\[
\mathbb{E}[\text{Cov}(Z_{m+1}, Z_{m+2}) | U] \leq 2\sqrt{\mathbb{E} \left[ \sqrt{\mathbb{E}[Z_{m+1} | U] \mathbb{E}[Z_{m+2} | U]} \right]} \times \mathbb{E}[I(Z_{m+1}; Z_{m+2} | U)]
\]
where (a) follows from the Cauchy-Schwarz inequality and (b) follows from (29).

Combining (114), (115), (116), (117), and (118) yields
\[
\mathbb{E}[|\mathcal{E} - \bar{\mathcal{E}}|] \leq C_B \cdot |I(Z_{m+1}; Z_{m+2} | U)|^{1/4},
\]
where (a) follows from the Cauchy-Schwarz inequality and (b) follows from (29).

Thus, in order to complete the proof, we need to show that the mutual information term can be upper bounded in terms of the second order MI difference sequence. To this end, observe that
\[
\mathbb{E}[|\mathcal{E} - \bar{\mathcal{E}}|] \leq C_B \cdot |I(Z_{m+1}; Z_{m+2} | U)|^{1/4},
\]
where (a) and (b) both follow from the data processing inequality for mutual information, (c) follows from the fact that, given \( (U, A_{m+1}) \), there is a one-to-one mapping between \( Z_{m+1} \) and \( Y_{m+1} \), (d) follows from the fact that measurements are generated independently of everything else (Assumption 1), and (e) follows from (15). This completes the Proof of Inequality (33).

2) Proof of Inequality (34): The main idea behind this proof is to combine identity (31) with the covariance bound in Lemma 33. The only tricky part is that the expectation with respect to \( (A_{m+1}, A_{m+2}) \) is taken with respect to the squared Frobenius norm whereas the expectation with respect to \( U \) is taken with respect to the square root of this quantity.

To begin, observe that for each realization \( U = u \), we have
\[
\frac{1}{n^2}\mathbb{E}[\text{Cov}(X^n | U = u)]^2 \leq \mathbb{E}[\text{Cov}(Y_{m+1}, Y_{m+2} | U = u) | A_{m+2}]^2
\]
where (a) follows from the Cauchy-Schwarz inequality and (b) follows from (28), and (c) follows from Jensen’s Inequality, (b) follows from (28), and (c) follows from (15). This completes the Proof of Inequality (34).

D. Proof of Lemma 15

The mutual information difference density can be decomposed as
\[
\mathcal{J}_{m,n} = \mathcal{I}(X^n; \bar{Y}_{m+1} | Y^m, A^{m+1}) - \mathcal{I}(X^n; Y_{m+1}, A^{m+1}) - \frac{1}{2} \log(2\pi) - \frac{1}{2} W_2^2
\]
where \( \mathcal{I}(X^n; \bar{Y}_{m+1} | Y^m, A^{m+1}) \) denotes the conditional density function of the centered measurement evaluated with the random data \( (Y^n, A^{m+1}) \). Therefore, for every \( \sigma^2 > 0 \), the Kullback–Leibler divergence between \( P_{\bar{Y}_{m+1}|Y_{m+1}, A_{m+1}} \) and the Gaussian distribution \( N(0, \sigma^2) \) can be expressed as
\[
D_{\text{KL}} \left( P_{\bar{Y}_{m+1}|Y_{m+1}, A_{m+1}} \left| N(0, \sigma^2) \right. \right) = \int \left( \frac{1}{2\sigma^2} y^2 + \frac{1}{2} \log(2\pi\sigma^2) \right) f_{\bar{Y}_{m+1}|Y_{m+1}, A_{m+1}}(y) dy + \int \log \left( f_{\bar{Y}_{m+1}|Y_{m+1}, A_{m+1}}(y) \right) f_{\bar{Y}_{m+1}|Y_{m+1}, A_{m+1}}(y) dy
\]
\[= \frac{1}{2\sigma^2} \mathbb{E}[Y_{m+1}^2 | Y^m, A^{m+1}] + \frac{1}{2} \log(2\pi\sigma^2) - \mathbb{E}[J_{m+n} | Y^m, A^{m+1}] - \frac{1}{2} \log(2\pi) - \frac{1}{2}.\]

Taking the expectation with respect to \( A_{m+1} \) and rearranging terms leads to
\[
\mathbb{E}_{A_{m+1}} \left[ D_{\mathrm{KL}}(P_{Y_{m+1} | Y^m, A^{m+1}} \| \mathcal{N}(0, \sigma^2)) \right] = \frac{1}{2} \log(\sigma^2) - J_{m+n} + \frac{1}{2} \left( \frac{1 + V_{m,n}}{\sigma^2} - 1 \right),
\]

where we have used the fact that the conditional variance is given by (36).

At this point, Identity (35) follows immediately by letting \( \sigma^2 = 1 + V_{m,n} \). For Identity (39), let \( \sigma^2 = 1 + M_{m,n} \) and note that the expectation of the last term in (119) is equal to zero.

**E. Proof of Lemma 17**

The error vector \( \widetilde{X}^n = X^n - \mathbb{E}[X^n | Y^m, A^m] \) has mean zero by construction. Therefore, by (35) and Lemma 16 the posterior non-Gaussianity satisfies
\[
\Delta_{m,n}^P \leq \frac{1}{2} \mathbb{E}[|\mathcal{E}_{m,n} - V_{m,n}| | Y^m, A^m] + C \cdot \frac{1}{n} \| \text{Cov}(X^n | Y^m, A^m) \|_F \left( 1 + \overline{V}_{m,n} \right)^\frac{1}{2},
\]

where \( \overline{V}_{m,n} = \sqrt{\mathbb{E}[\mathcal{E}_{m,n}^2 | Y^m, A^m]} \). Taking the expectation of both sides and using the Cauchy-Schwarz inequality and Jensen’s inequality leads to
\[
\mathbb{E}[\Delta_{m,n}^P] \leq \frac{1}{2} \mathbb{E}[|\mathcal{E}_{m,n} - V_{m,n}|] + C \cdot \frac{1}{n} \mathbb{E}[\| \text{Cov}(X^n | Y^m, A^m) \|_F] \left( 1 + \sqrt{\mathbb{E}[\mathcal{E}_{m,n}^2]} \right)^\frac{1}{2}.
\]

Furthermore, combining this inequality with Lemma 14 and 26 gives
\[
\mathbb{E}[\Delta_{m,n}^P] \leq C_B \cdot \left[ |I_{m,n}^I|^{\frac{1}{4}} + |I_{m,n}^I|^{\frac{1}{4}} \right].
\]

Finally, since \( |I_{m,n}^I| \) can be bounded uniformly by a constant that depends only on \( B \), we see that the dominant term on the right-hand side is the one with the smaller exponent. This completes the proof.

**F. Proof of Lemma 18**

To simplify notation we drop the explicit dependence on the problem parameters and write \( M \) and \( V \) instead of \( M_{m,n} \) and \( V_{m,n} \). The first inequality in (41) follows immediately from the fact that the mapping \( x \mapsto \log(1 + x) \) is one-Lipschitz on \( \mathbb{R}_+ \).

Next, letting \( V' \) be an independent copy of \( V \), the absolute deviation of the posterior variance can be upper bounded as follows:
\[
\mathbb{E}[|V - M|] = \mathbb{E}[|V - \mathbb{E}[V']|] \leq \mathbb{E}[|V - V'|]
\]

where (a) follows from Jensen’s inequality and (b) follows from applying Lemma 30 with \( X = 1 + V_m \) and \( Y = 1 + V'_m \).

The first expectation on right-hand side of (120) from (a) follows immediately from (39) and (b) follows form Jensen’s inequality and (25).

For the second expectation on the right-hand side of (120), we observe that the triangle inequality, we have, for every \( t \in \mathbb{R} \),
\[
|\log \left( \frac{1 + V}{1 + V'^2} \right)| \leq |\log(1 + V) - t| + |\log(1 + V') - t|.
\]

Taking the expectation of both sides and minimizing over \( t \) yields
\[
\mathbb{E}\left[ \log \left( \frac{1 + V}{1 + V'^2} \right) \right] \leq \min_{t \in \mathbb{R}} 2\mathbb{E}[|\log(1 + V) - t|].
\]

Plugging (120) and (121) back into (122) completes the proof of Lemma 18.

**G. Proof of Lemma 19**

Let \( U = (Y^m, A^m) \) and \( U_k = (Y_{m+k}^m, A_{m+k}^m) \). We use the fact that the posterior variance can be expressed in terms of the expected variance of a future measurement. Specifically, by (30), it follows that for any integer \( i > m + k \), we have
\[
V_{m+k} = \mathbb{E}_{A_i}[\mathbb{E}(Y_i | U, A_i)] - 1 \quad \text{and} \quad V_{m+k} = \mathbb{E}_{A_i}[\mathbb{E}(Y_i | U, A_i)] - 1.
\]

Accordingly, the expected difference in absolute values can be upper bounded as
\[
\mathbb{E}[|V_{m+k} - V_m|] = \mathbb{E}[|\mathbb{E}_{A_i}[\mathbb{E}(Y_i | U, A_i)] - \mathbb{E}_{A_i}[\mathbb{E}(Y_i | U, A_i)]|] \leq \mathbb{E}[|\mathbb{E}(Y_i | U, A_i) - \mathbb{E}(Y_i | U, A_i)|] \leq C \cdot \sqrt{\mathbb{E}[|Y_i|^4] \mathbb{E}[D_{\mathrm{KL}}(P_{Y_i | U, A_i} \| P_{Y_i | U, A_i})]} \leq C_B \cdot \sqrt{\mathbb{E}[D_{\mathrm{KL}}(P_{Y_i | U, A_i} \| P_{Y_i | U, A_i})]},
\]

where (a) follows from Jensen’s inequality, (b) follows from Lemma 32 with \( p = 1 \), and (c) follows from (28).

Next, the expected Kullback-Leibler divergence can be expressed in terms of a conditional mutual information,
\[
\mathbb{E}[D_{\mathrm{KL}}(P_{Y_i | U, A_i} \| P_{Y_i | U, A_i})] = I(Y_i; U_k | U, A_i)
\]

where (a) follows from Jensen’s inequality, (b) follows from Lemma 32 with \( p = 1 \), and (c) follows from (28).

Next, the expected Kullback-Leibler divergence can be expressed in terms of a conditional mutual information,
where (a) follows from the definitions of $U$ and $U_k$, and the fact that the measurements are independent of everything else, (b) follows from expanding the mutual information in terms of the differential entropy of $Y_i$, (c) follows from the fact that future measurements are identically distributed given the past, (d) follows from the fact that $h(W_m) = h(Y_m | X^n, A^m)$, and (e) follows from (14).

Combining (123) and (124), we see that the following inequality holds for all integers $m$ and $k$,

$$E[|V_{m,n} - V_{k,n}|] \leq C_B \cdot |I'_{m,n} - I'_{k,n}|^{\frac{1}{2}}.$$  

Moreover, we can now bound the deviation over $\ell$ measurements using

$$\frac{1}{\ell} \sum_{i=m}^{m+\ell-1} E[|V_m - V_k|] \leq C_B \cdot \frac{1}{\ell} \sum_{i=m}^{m+\ell-1} |I'_{m} - I'_{k}|^{\frac{1}{2}} \leq C_B \cdot |I'_{m} - I'_{m+\ell-1}|^{\frac{1}{2}},$$

where the second inequality follows from the fact that $I'_{m,n}$ is non-increasing in $m$ (see Section III-B). This completes the proof of Lemma 19.

**H. Proof of Lemma 20**

Starting with the triangle inequality, the sum of the posterior MI difference satisfies for all $t \in \mathbb{R}$,

$$\sum_{i=m}^{m+\ell-1} J_i - t \leq \sum_{i=m}^{m+\ell-1} J_i - J_i + \sum_{i=m}^{m+\ell-1} J_i - t.$$

Taking the expectation of both sides and minimizing over $t$ leads to

$$\inf_{t \in \mathbb{R}} E \left[ \sum_{i=m}^{m+\ell-1} J_i - t \right] \leq \inf_{t \in \mathbb{R}} E \left[ \sum_{i=m}^{m+\ell-1} J_i - J_i \right] + \sum_{i=m}^{m+\ell-1} E \left[ J_i - t \right].$$

For the first term in (125), observe that

$$\inf_{t \in \mathbb{R}} E \left[ \sum_{i=m}^{m+\ell-1} J_i - t \right] \leq \inf_{t \in \mathbb{R}} E \left[ \sum_{i=m}^{m+\ell-1} J_i - J_i \right] \leq \sqrt{\text{Var} \left( \sum_{i=m}^{m+\ell-1} J_i \right)},$$

where (a) follows from Jensen’s inequality. Furthermore, the variance obeys the upper bound

$$\text{Var} \left( \sum_{i=m}^{m+\ell-1} J_i \right) = \text{Var} \left( \sum_{i=0}^{m+\ell-1} J_i - \sum_{i=0}^{m-1} J_i \right) \leq 2 \text{Var} \left( \sum_{i=0}^{m+\ell-1} J_i \right) + 2 \text{Var} \left( \sum_{i=0}^{m-1} J_i \right) \leq 2 \text{Var} \left( \sum_{i=0}^{m+\ell-1} J_i - \sum_{i=0}^{m-1} J_i \right) + 2 \text{Var} \left( \sum_{i=0}^{m-1} J_i \right).$$

Next, we consider the second term in (125). Note that $J_m$ can be expressed explicitly as follows:

$$J_m = \log \left( \frac{f_{Y_m+1|X^n,Y_m,A^m+1}(Y_{m+1} | Y_m, A^m)}{f_{Y_{m+1}|Y_{m+1},A^m+1}(Y_{m+1} | Y_m, A^m)} \right) = - \log \left( f_{Y_{m+1}|Y_{m+1},A^m}(Y_{m+1} | Y_m, A^m) \right) - \frac{1}{2} W_{m+1}^2 - \frac{1}{2} \log(2\pi).$$

To proceed, we define the random variables

$$H_m \triangleq - \log \left( f_{Y_{m+1}|Y_m,A^m}(Y_{m+1} | Y_m, A^m) \right),$$

and observe that

$$J_m = H_m - \frac{1}{2} W_{m+1}^2 - \frac{1}{2} \log(2\pi).$$

Using this notation, we can now write

$$E \left[ \sum_{i=m}^{m+\ell-1} J_i - J_i \right] = E \left[ \sum_{i=m}^{m+\ell-1} H_i - \hat{H}_i \right] + \frac{1}{2} E \left( \sum_{i=m}^{m+\ell-1} W_i^2 - 1 \right).$$

where (a) follows from the triangle inequality and (b) follows from Jensen’s inequality. For the first term on the right-hand side, observe that square of the sum can be expanded as follows:

$$E \left( \sum_{i=m}^{m+\ell-1} W_i^2 - 1 \right) = \sum_{i=m}^{m+\ell-1} E \left( W_i^2 - 1 \right).$$
\[
+ 2 \sum_{i=m}^{m+\ell-1} \sum_{j=i+1}^{m+\ell-1} \mathbb{E} \left[ (\mathcal{H}_i - \hat{\mathcal{H}}_i) (\mathcal{H}_j - \hat{\mathcal{H}}_j) \right].
\]

(129)

To deal with the first term on the right-hand side of (129), observe that
\[
\mathbb{E} \left[ (\mathcal{H}_i - \hat{\mathcal{H}}_i)^2 \right] \overset{(a)}{=} \mathbb{E} \left[ \text{Var}(\mathcal{H}_i \mid Y^i, A^i) \right]
\leq \mathbb{E} \left[ \left( \mathcal{H}_i - \frac{1}{2} \log(2\pi) \right)^2 \right],
\]

where (a) follows from the definition of \( \hat{\mathcal{H}}_i \) and (b) follows from the law of total variance. To bound the remaining term, let \( U = (Y^m, A^m) \) and let \( X_m \) be drawn according to the posterior distribution of \( X^n \) given \( U = u \). Then, the density of \( Y_{m+1} \) given \( (U, A_{m+1}) \) can be bounded as follows:
\[
\frac{1}{\sqrt{2\pi}} \geq f_{Y_{m+1} \mid U, A_{m+1}}(y_{m+1} \mid u, a_{m+1})
\leq \mathbb{E}_{X_m} \left[ \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{1}{2} (y_{m+1} - (a_{m+1}, \tilde{X}_U))^2 \right) \right]
\overset{(a)}{\geq} \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{1}{2} \mathbb{E}_{X_m} [(y_{m+1} - (a_{m+1}, \tilde{X}_U))^2] \right)
\overset{(b)}{\geq} \frac{1}{\sqrt{2\pi}} \exp \left( -y_{m+1}^2 - \mathbb{E}_{X_m} [(a_{m+1}, \tilde{X}_U))^2] \right),
\]

where (a) follows from Jensen’s inequality and the convexity of the exponential and (b) follows from [59]. Using these bounds, we obtain
\[
\mathbb{E} \left[ \left( \mathcal{H}_i - \frac{1}{2} \log(2\pi) \right)^2 \right]
\leq \mathbb{E} \left[ \left( \frac{m+\ell-1}{2} (a_{m+1}, \tilde{X}_U))^2 \right) \right]
\leq 2 \mathbb{E} \left[ Y_{m+1}^2 \right] + 2 \mathbb{E} \left[ \left( (a_{m+1}, \tilde{X}_U))^2 \right) \right]
\leq 2 \mathbb{E} \left[ (a_{m+1}, X^n))^4 \right]
\leq 4 \mathbb{E} \left[ Y_{m+1}^4 \right].
\]

(130)

As for the second term on the right-hand side of (128), note that \( \sum_{i=m}^{m+\ell-1} W_i^2 \) is chi-squared with \( \ell \) degrees of freedom, and thus
\[
\mathbb{E} \left[ \left( \sum_{i=m}^{m+\ell-1} (W_i^2 - 1) \right)^2 \right] = \frac{\ell}{2}.
\]

(131)

Plugging (130) and (131) back into (128) leads to
\[
\mathbb{E} \left[ \sum_{i=m}^{m+\ell-1} J_i - J_i \right] \leq C_B \cdot \sqrt{\ell}.
\]

Finally, combining this inequality with (125) and (127) gives
\[
\inf_{t \in \mathbb{R}} \mathbb{E} \left[ \sum_{i=m}^{m+\ell-1} J_i - t \right] \leq C_B \cdot \left( 1 + \frac{m+\ell}{n} \right) \left( \sqrt{n} + \sqrt{\ell} \right)
\leq C_B \cdot \left( 1 + \frac{m}{n} \right) \left( \sqrt{n} + \sqrt{\ell} \right),
\]

where the last step follows from keeping only the dominant terms. This completes the proof of Lemma 20.

1. Proof of Lemma 27

Fix any \( (m, n, \ell) \in \mathbb{N}^3 \). We begin with the following decomposition, which follows from the triangle inequality:
\[
\inf_{t \in \mathbb{R}} \mathbb{E} \left[ \frac{1}{2} \log(1 + V_m) - t \right]
\leq \mathbb{E} \left[ \frac{1}{2} \log(1 + V_m) - \frac{1}{\ell} \sum_{k=m}^{m+\ell-1} \frac{1}{2} \log(1 + V_k) \right]
\leq \mathbb{E} \left[ \frac{1}{\ell} \sum_{k=m}^{m+\ell-1} \frac{1}{2} \log(1 + V_k) - \frac{1}{k} \sum_{i=m}^{m+\ell-1} J_k \right]
\leq \inf_{t \in \mathbb{R}} \mathbb{E} \left[ \frac{1}{\ell} \sum_{i=m}^{m+\ell-1} J_k - t \right].
\]

(132)

The first term on the right-hand side of (132) can be bounded in terms of the smoothness of the mutual information given in Lemma 19. We use the following chain of inequalities:
\[
\mathbb{E} \left[ \log(1 + V_m) - \frac{1}{\ell} \sum_{k=m}^{m+\ell-1} \log(1 + V_k) \right]
\leq \mathbb{E} \left[ \log(1 + V_m) - \log(1 + V_k) \right]
\leq \frac{1}{\ell} \sum_{k=m}^{m+\ell-1} \mathbb{E} \left[ |I'_m - I'_{m+\ell-1}|^2 \right]
\leq C_B \cdot \left( |I'_m - I''_{m+\ell-1}| \right)^{1/2}
\]

(133)

where (a) follows from Jensen’s inequality, (b) follows from the fact that the mapping \( \log(1 + x) \to x \) is one-Lipschitz on \( \mathbb{R}_+ \), and (c) follows from Lemma 19.
The second term on the right-hand side of (132) is bounded by the relationship between the posterior variance and posterior mutual information difference:

\[
\mathbb{E} \left[ \frac{1}{\ell} \sum_{k=m}^{m+\ell-1} \frac{1}{2} \log(1 + V_k) - \frac{1}{\ell} \sum_{k=m}^{m+\ell-1} J_k \right]
\]

\[= \frac{1}{\ell} \sum_{k=m}^{m+\ell-1} \mathbb{E} [\Delta_k^P] \]

\[\leq C_B \cdot \frac{1}{\ell} \sum_{k=m}^{m+\ell-1} |I_k'|^{\frac{1}{10}} \]

\[\leq C_B \cdot \frac{1}{\ell} \sum_{k=m}^{m+\ell-1} \left( \frac{1}{m+\ell} \right)^{\frac{1}{10}} \]

\[= C_B \left( \frac{1}{\ell} \right) \ell^{-\frac{1}{10}}, \tag{134} \]

where (a) follows from Identity (38), (b) follows from Lemma 17, (c) follows from Jensen’s inequality and the non-positivity of \(I''_m\) and (d) follows from the fact that \(I'_m\) is bounded by a constant that depends only on \(B\) (see Section III-B).

Finally, the third term on the right-hand side of (132) is bounded by Lemma 20. Plugging (133) and (134) back into (132) leads to

\[
\inf_{t \in \mathbb{R}} \mathbb{E} \left[ \frac{1}{2} \log(1 + V_m) - t \right] \leq C_B \cdot \left| I'_m - I'_m + I'_m \right|^{\frac{1}{2}} + C_B \cdot \left( \ell^{-\frac{1}{10}} + \left( 1 + \frac{m}{n} \right)^{\frac{1}{2}} \right) \frac{1}{\ell}. \]

Combining this inequality with Lemma 18 completes the proof of Lemma 21.

**J. Proof of Lemma 22**

Fix any \((m, n, \ell) \in \mathbb{N}^3\). Combining Identity (40), with Lemmas 17 and 21 yields

\[
\Delta_{m, n} = \mathbb{E} [\Delta_{m, n}^P] + \frac{1}{2} \mathbb{E} \left[ \log \left( \frac{1 + M_{m, n}}{1 + V_{m, n}} \right) \right]
\]

\[\leq C_B \cdot \left( \frac{1}{m+\ell} \right)^{\frac{1}{10}} + \left( 1 + \frac{m}{n} \right)^{\frac{1}{10}} \ell^{-\frac{1}{10}} + \left( 1 + \frac{m}{n} \right)^{\frac{1}{10}} \ell^{-\frac{1}{10}} + n^{-\frac{1}{10}} \tag{135} \]

For the specific choice of \(\ell = \lceil \frac{n}{2} \rceil\), we have

\[
\ell^{-\frac{1}{10}} + \left( 1 + \frac{m}{n} \right)^{\frac{1}{10}} \frac{1}{n} + \left( 1 + \frac{m}{n} \right)^{\frac{1}{10}} \frac{1}{n} \leq n^{-\frac{1}{10}} + \left( 1 + \frac{m}{n} \right)^{\frac{1}{10}} \frac{1}{n} \leq 2 \left( 1 + \frac{m}{n} \right)^{\frac{1}{10}} \frac{1}{n}.
\]

Plugging this inequality back into (135) completes the proof of Lemma 22.

**APPENDIX D**

**PROOFS OF RESULTS IN SECTION VII**

**A. Proof of Lemma 23**

Recall that \(M_m\) is the expectation of the posterior variance \(V_m\). Therefore, the difference between \(M_{m+1}\) and \(M_m\) can be bounded as follows:

\[
|M_{m+1} - M_m| = |\mathbb{E}[V_{m+1} - V_m]|
\]

\[\leq \mathbb{E}[|V_{m+1} - V_m|] \leq C_B \cdot \sqrt{\Delta_m} \tag{136} \]

where (a) follows from Jensen’s inequality and (b) follows from Lemma 19. Combining (136) with the sandwiching relation (46) leads to (47).

**B. Proof of Lemma 24**

Let \(Q\) be a random matrix distributed uniformly on the set of \((m+1) \times (m+1)\) orthogonal matrices and define the rotated augmented measurements:

\[
\tilde{Y}^{m+1} = Q \left( Y^m | Z_{m+1} \right), \quad \tilde{A}^{m+1} = Q \left( A^m | \tilde{A}^{m+1} \right).
\]

Since multiplication by \(Q\) is a one-to-one transformation, the augmented MMSE can be expressed equivalently in terms of the rotated measurements:

\[
\tilde{M}_m = \frac{1}{n} \text{mmse}(X^n | Y^m, A^m, D_{m+1}) = \frac{1}{n} \text{mmse}(X^n | \tilde{Y}^{m+1}, \tilde{A}^{m+1}). \tag{137} \]

**Lemma 35.** The entries of the \((m + 1) \times (n + 1)\) random matrix \(\tilde{A}^{m+1}\) are i.i.d. Gaussian \(\mathcal{N}(0, 1/n)\).

**Proof:** The first \(n\) columns are i.i.d. Gaussian \(\mathcal{N}(0, \frac{1}{n} I_{m+1})\) and independent of \(Q\) because of the rotational invariance of the i.i.d. Gaussian distribution on \(A^{m+1}\). The last column of \(A^{m+1}\) is equal to the product of \(\sqrt{G_m}\) and the last column of \(Q\). Since \(G_m\) is proportional to a chi random variable with \(m + 1\) degrees of freedom and \(Q\) is distributed uniformly on the \(n + 1\) dimensional Euclidean sphere, the last column is also Gaussian \(\mathcal{N}(0, \frac{1}{n} I_{m+1})\); see e.g. [45, Theorem 2.3.18].

The key takeaway from Lemma 35 is that the distribution on the columns of \(\tilde{A}^{m+1}\) is permutation invariant. Since the distribution on the entries of \(X^{n+1}\) is also permutation invariant, this means that the MMSEs of the signal entries are identical, i.e.,

\[
\text{mmse}(X_j | Y^{m+1}, \tilde{A}^{m+1}) = \text{mmse}(X_j | \tilde{Y}^{m+1}, \tilde{A}^{m+1}),
\]

for all \(i, j \in [n+1]\). Combining this fact with (137), we see that the augmented MMSE can be expressed equivalently as

\[
\tilde{M}_m = \text{mmse}(X_{n+1} | \tilde{Y}^{m+1}, \tilde{A}^{m+1}) = \text{mmse}(X_{n+1} | Y^m, A^m, D_{m+1}),
\]

where the last step follows, again, from the fact that multiplication by \(Q\) is a one-to-one transformation of the data. This completes the proof of Lemma 24.
C. Proof of Lemma 25

This proof is broken into two steps. First, we show that the augmented MMSE satisfies the inequality,

$$\|\tilde{M}_m - \mathbb{E}[\text{mmse}_X(G_{m+1} + 1 + M_m)]\| \leq C_B \cdot \sqrt{\Delta_m}. \quad (138)$$

Then, we use the smoothness of the single-letter MMSE function $\text{mmse}_X(s)$ to show that

$$\mathbb{E}[\text{mmse}_X(G_{m+1} + 1 + M_m)] - \text{mmse}_X(m/n) \leq C_B \frac{1 + \sqrt{m}}{n}. \quad (139)$$

The proofs of Inequalities (138) and (139) are given in the following subsections.

1) Proof of Inequality (138): The centered augmented measurement $\tilde{Z}_{m+1}$ is defined by

$$\tilde{Z}_{m+1} = Z_{m+1} - \mathbb{E}[Z_{m+1} | Y^m, A^{m+1}].$$

Since $G_{m+1}$ and $X_{n+1}$ are independent of the first $m$ measurements, $Z_{m+1}$ can also be expressed as

$$Z_{m+1} = \sqrt{G_{m+1}} X_{n+1} + \bar{Y}_{m+1},$$

where $\bar{Y}_{m+1} = Y_{m+1} - \mathbb{E}[Y_{m+1} | Y^m, A^{m+1}]$ is the centered measurement introduced in Section IV-C. Starting with (48), we see that the augmented MMSE can be expressed as

$$\tilde{M}_m = \text{mmse}(X_{n+1} | Y^m, A^m, \tilde{Z}_{m+1}, A_{m+1}, G_{m+1}), \quad (140)$$

where we have used the fact that there is a one-to-one mapping between $\tilde{Z}_{m+1}$ and $Z_{m+1}$.

The next step of the proof is to address the extent to which the MMSE in (140) would differ if the ‘noise’ term $\bar{Y}_{m+1}$ were replaced by an independent Gaussian random variable with the same mean and variance. To make this comparison precise, recall that $\mathbb{E}[\bar{Y}_{m+1}^2] = 0$ and $\text{Var}(\bar{Y}_{m+1}) = 1 + M_m$, and let $Z^*_{m+1}$ be defined by

$$Z^*_{m+1} = \sqrt{G_{m+1}} X_{n+1} + Y^*_{m+1},$$

where $Y^*_{m+1} \sim \mathcal{N}(0, 1 + M_m)$ is independent of everything else. Note that the MMSE of $X_{n+1}$ with $Z^*_{m+1}$ replaced by $Z^*_{m+1}$ can be characterized explicitly in terms of the single-letter MMSE function:

$$\text{mmse}(X_{n+1} | Y^m, A^m, Z^*_{m+1}, A_{m+1}, G_{m+1}) \overset{(a)}{=} \text{mmse}(X_{n+1} | Z_{m+1}, A_{m+1}, G_{m+1}) \overset{(b)}{=} \mathbb{E}[\text{mmse}_X(G_{m+1} + 1 + M_m)] \quad (141)$$

where (a) follows from the fact that $(Y^m, A^{m+1})$ is independent of $(X_{n+1}, Z_{m+1}, G_{m+1})$.

The next step is to bound the difference between (140) and (141). To proceed, we introduce the notation

$$F = (Y^m, A^m, Z_{m+1}, A_{m+1}, G_{m+1})$$

$$F^* = (Y^m, A^m, Z^*_{m+1}, A_{m+1}, G_{m+1}).$$

Then, using Lemma 34 yields

$$|\text{mmse}(X_{n+1} | F) - \text{mmse}(X_{n+1} | F^*)| \leq 2^{\frac{2}{s}} \sqrt{\mathbb{E}[X_{n+1}^4]} D_{KL}(P_{F, X_{n+1}} || P_{F^*, X_{n+1}}).$$

By Assumption 2, the fourth moment of $X_{n+1}$ is upper bounded by $B$. The last step is to show that the Kullback–Leibler divergence is equal to the non-Gaussianness $\Delta_m$. To this end, observe that

$$D_{KL}(P_{F, X_{n+1}} || P_{F^*, X_{n+1}}) \overset{[3]}{=} \mathbb{E}[X_{n+1}] D_{KL}(P_{F|X_{n+1}} || P_{F^*|X_{n+1}})$$

$$\overset{(b)}{=} D_{KL}(P_{Y_{m+1} = Y^m, A_{m+1}} || P_{Y^*_{m+1} = Y^m, A_{m+1}})$$

$$\overset{(c)}{=} \mathbb{E}_{Y^m, A_{m+1}}[D_{KL}(P_{Y_{m+1} = Y^m, A_{m+1}} || P_{Y^*_{m+1}})] = \Delta_m,$$

where (a) follows from the chain rule for Kullback–Leibler divergence, (b) follows from the fact that both $Y_{m+1}$ and $Y^*_{m+1}$ are independent of $(X_{n+1}, G_{m+1})$, and (c) follows from the chain rule for Kullback–Leibler divergence and the fact that $Y^*_{m+1}$ is independent of $(Y^m, A^{m+1})$. This completes the proof of Inequality (138).

2) Proof of Inequality (139): Observe that

$$|\mathbb{E}[\text{mmse}_X(G_{m+1} + 1 + M_m)] - \text{mmse}_X(m/n) | \leq 4B \frac{\|G_{m+1} - m/n\|}{n}$$

$$\leq 4B \left( \mathbb{E}[|G_{m+1} - m/n|^2] + \frac{1}{n} \right)$$

$$\leq 4B \left( \sqrt{\text{Var}(G_{m+1})} + \frac{1}{n} \right)$$

$$= 4B \left( \sqrt{2(m+1) + 1/n} \right),$$

where (a) follows from Jensen’s inequality, (b) follows from Lemma 3 and Assumption 2, (c) follows from the triangle inequality and the fact that $\mathbb{E}[G_{m+1}] = m/n$, and (d) follows from Jensen’s inequality.

ACKNOWLEDGMENT

G. Reeves is grateful to D. Donoho for many helpful conversations as well as the inspiration behind the sandwiching argument that lead to the fixed-point relationships in Section V-A.
