Abstract: Varicocele is the most common correctable male infertility factor and varicocelectomy has been a mainstay in the management of infertility. However, the role of varicocelectomy as a treatment option has been controversial, and the scientific debate around it is still ongoing. Our study aimed to explore the role of anthropometric variables of infertile patients and their relation to sperm parameters following varicocelectomy. The outcome of 124 infertile patients who underwent open sub-inguinal varicocelectomy by a single surgeon over the last ten years was studied. Post varicocelectomy, four semen parameters (volume, total count, motility, and morphology) were analyzed and adjusted according to anthropometric variables including age, varicocele grade, and body mass index (BMI) of patients. Total count and motility were significantly improved after surgery. Varicocelectomy improved semen parameters, notably the count and the motility, especially in younger patients, lower grades of varicocele patients, and low BMI patients. In addition, BMI was positively correlated with volume in pre-varicocelectomy and post-varicocelectomy.

Keywords: body mass index; varicocele; varicocelectomy

1. Introduction

Infertility affects 15% of all couples who are intending to conceive [1]. Male factors alone contribute to 20–30% of all infertility cases, and when combined with the female element, it is responsible for 50% of overall cases [2]. Varicocele is known to be the most common correctable male infertility etiology [3].
Several studies have reported the prevalence of varicocele as 15–20% in healthy subjects, and 40–70% in men with infertility [4,5]. The exact pathophysiological mechanism explaining how varicocele affects testicular function is still uncertain. However, several studies have reported that a reduced testicular volume, weak sperm parameters, and changes in testosterone levels in infertile men have been observed in patients with varicocele [6].

Therefore, varicocele correction has been a mainstay in the treatment of male infertility. The current guidelines recommend treatment of varicocele should be performed in cases of documented infertility, in the presence of one or more abnormal semen parameters of sperm function tests, in palpable varicocele, and in normal female fertility or potentially correctable female fertility [7]. However, the efficacy of varicocele repair in infertile males has been controversial. Improvement in sperm parameters and testicular volume after varicocele repair has been reported in the literature, yet its correlation with spontaneous pregnancy has been unclear [8,9].

The prevalence of varicocele increases with decreasing BMI (body mass index) and is associated with adipose tissue compression of the left renal vein [10]. Although there are many studies on the correlation between BMI and the prevalence of varicocele [11], there are no studies that have compared semen parameters according to BMI after varicocelectomy [4,6,12]. Our study aimed to compare pre- and post-operative semen parameters and testicular volume according to anthropometric parameters following sub-inguinal varicocelectomy performed consistently by the same surgeon over ten years, and to assess post-operative fertility concerning changes in the sperm parameters and testicular volume.

2. Methods

2.1. Study Populations

Data were collected from clinical charts of a single surgeon, and a retrospective data analysis was done in a single center in Lebanon [13]. The person responsible for the data collection included all the charts of infertile males with varicocele (clinically proven unilateral or bilateral varicocele with abnormal semen parameters), who had undergone varicocelectomy between 2007 and 2016, incorporating a total of 124 patients in the study. Demographic and anthropometric data regarding the patients, including, but limited to, age, hormonal profile, testicular size, physical exam, ultrasound results, co-morbidities, and sperm analysis pre- and post-varicocelectomy were collected and tabulated in an Excel sheet. Post-varicocelectomy semen analysis was taken systematically 2 months postoperatively. However, we did not follow up with patients who had multiple semen analyses on follow up. Patients were then grouped according to age, grade of the varicocele, and BMI. Patients with previous pelvic or urologic surgeries, who might have been at risk of developing obstructive azoospermia, were excluded. This study was approved by the American University of Beirut Medical Center’s Institutional Review Board (ID: SUR.MB.05) on 21 June 2017. Our study was conducted according to the ethical standards laid down in the 1964 Declarations of Helsinki and its later amendments.

2.2. Statistical Analysis

Exploratory data analysis (EDA) was carried out describing the central tendency (e.g., mean, median) and distribution (e.g., standard deviation, 95% confidence interval) of the various variables. A paired t-test was used to compare the variables before and after surgery. One-way ANOVA was also used to describe the distribution of a continuous measure according to different categories (age groups or varicocele grade). Scheffé analysis was done as a post-hoc analysis if indicated. If the number of patients in each group did not exceed twenty subjects, analysis was performed by a nonparametric test (Wilcoxon signed-rank test). We categorized the patients into two groups (high BMI and low BMI) based on the median value of the BMI level (28.6) because of the limited number of patients. Spearman correlation analysis was performed to analyze the correlation between BMI and other continuous parameters. All statistical analyses were performed with the IBM Statistical Package for the Social
Sciences (SPSS), version 23.0 (IBM Corporation, Armonk, NY, USA). All differences were considered statistically significant at a \( p \)-value < 0.05.

3. Results

3.1. Characteristics of the Patients

A total of 124 men were evaluated for pre- and post-operative parameters following varicocelectomy. The demographics and features of the patients are presented in Table 1, which show that 83.8% of patients were under 40 years, and 76% and 70.5% of patients had grade I or II varicocele, respectively, on physical exam and ultrasound.

Table 1. Characteristics of patients receiving varicocelectomy.

| Characteristics                  | Number of Patients (%) |
|----------------------------------|------------------------|
| Age (years)                      |                        |
| <30                              | 52 (41.9%)             |
| 30–40                            | 52 (41.9%)             |
| 40–49                            | 18 (14.4%)             |
| >50                              | 2 (1.6%)               |
| Varicocele grade on PEx          |                        |
| I                                | 22/100 (22%)           |
| II                               | 54/100 (54%)           |
| III–IV                           | 24/100 (24%)           |
| Varicocele grade on US           |                        |
| I                                | 9/61 (14.8%)           |
| II                               | 34/61 (55.7%)          |
| III–IV                           | 18/61 (29.5%)          |
| Side of varicocele               |                        |
| Left                             | 44/90 (48.9%)          |
| Right                            | 0/90 (0%)              |
| Bilateral                        | 46/90 (51.1%)          |
| Bodyweight                       |                        |
| BMI < 28.6                       | 60/121 (49.6%)         |
| BMI ≥ 28.6                       | 61/121 (50.4%)         |

BMI: Body mass index; PEx: physical examination; US: Ultrasound.

3.2. Pre- and Post-Varicocelectomy Semen Parameters

The total count and the motility showed a statistically significant improvement after operation (Table 2). This improvement was observed in both groups, the high BMI group (total count: 16.26 ± 19.25 million/mL vs. 22.17 ± 22.99 million/mL, \( p = 0.018 \); and motility: 38.44% ± 19.67% vs. 43.85% ± 19.07%, \( p = 0.026 \)), and the low BMI group (total count: 17.07 ± 17.81 million/mL vs. 29.50 ± 43.70 million/mL, \( p = 0.010 \); and motility: 36.77% ± 18.47% vs. 42.95% ± 18.27%, \( p = 0.002 \)). In subgroup analysis, both groups showed no significant improvement in volume and morphology.

Table 2. Pre- and post-varicocelectomy semen parameters (volume, total count, motility, and morphology).

| Parameters               | Pre-Operative     | Post-Operative | \( p \)-Value |
|--------------------------|-------------------|----------------|--------------|
| Volume (mL)              | 3.46 ± 1.63       | 3.51 ± 1.46    | 0.703        |
| Total count (million/mL) | 16.89 ± 18.20     | 26.18 ± 34.29  | <0.001       |
| Motility (%)             | 37.23 ± 19.13     | 43.23 ± 18.48  | <0.001       |
| Morphology (%)           | 47.22 ± 20.25     | 47.67 ± 22.04  | 0.864        |

3.3. Subgroup Analysis of Pre- and Post-Varicocelectomy Semen Parameters

When dividing the population according to age groups, the improvement in the total count was most significant in the group of patients <30 years, increasing from 19.28 ± 19.08 million/mL to 31.81 ± 43.87 million/mL (\( p = 0.018 \)), and a significant change was also evident among patients aged between 30 and 40 years, with an increase from 13.92 ± 15.89 million/mL to 21.30 ± 25.24 million/mL (\( p = 0.016 \)). As for motility, there was a statistically significant increase across all age groups;
however, the highest age group (40–49 years) showed the greatest increase from 34.61% ± 19.91% to 43.56% ± 19.03% with a \( p \)-value of 0.048 (Table 3).

Table 3. Pre- and post-varicocelectomy semen parameters by age groups.

| Age   | Parameters | Pre-Operative | Post-Operative | \( p \)-Value |
|-------|------------|---------------|----------------|--------------|
| <30   | Volume (mL)| 3.51 ± 1.55   | 3.70 ± 1.60    | 0.385        |
|       | Total count (million/mL) | 19.28 ± 19.08 | 31.85 ± 43.87 | 0.018        |
|       | Motility (%) | 38.04 ± 18.59 | 43.65 ± 16.89 | 0.016        |
|       | Morphology (%) | 50.30 ± 18.98 | 53.85 ± 22.01 | 0.573        |
| 30–40 | Volume (mL) | 3.38 ± 1.72   | 3.29 ± 1.29    | 0.669        |
|       | Total count (million/mL) | 13.92 ± 15.89 | 21.30 ± 25.24 | 0.016        |
|       | Motility (%) | 38.17 ± 19.31 | 43.40 ± 19.49 | 0.028        |
|       | Morphology (%) | 45.90 ± 22.53 | 41.86 ± 21.44 | 0.130        |
| 40–49 | Volume (mL) | 3.63 ± 1.65   | 3.72 ± 1.46    | 0.850        |
|       | Total count (million/mL) | 20.19 ± 21.39 | 26.35 ± 23.62 | 0.216        |
|       | Motility (%) | 34.61 ± 19.91 | 43.56 ± 19.03 | 0.048        |
|       | Morphology (%) | 48.33 ± 14.32 | 51.58 ± 17.61 | 0.481        |

The total count after varicocelectomy improved in grade I varicocele patients (on ultrasound), from 15.70 ± 14.67 million/mL to 23.80 ± 27.13 million/mL (\( p = 0.05 \)) and in grade II patients from 18.04 ± 18.52 million/mL to 28.02 ± 35.51 million/mL (\( p = 0.004 \)). Motility also improved in grade I patients from 32.38% ± 18.28% to 41.86% ± 16.72% (\( p = 0.004 \)), and in grade II patients from 39.20% ± 16.80% to 45.93% ± 18.37% (\( p = 0.004 \)). In contrast, morphology only improved in grade I varicocele patients post-operatively, from 43.30% ± 18.77% to 50.71% ± 18.15% (\( p = 0.01 \)) (Table 4).

Table 4. Semen parameters pre- and post-varicocelectomy according to the grade of the varicocele.

| Grade | Parameters | Pre-Operative | Post-Operative | \( p \)-Value |
|-------|------------|---------------|----------------|--------------|
| I     | Volume (mL)| 3.58 ± 1.66   | 3.70 ± 1.60    | 0.719        |
|       | Total count (million/mL) | 15.70 ± 14.67 | 23.80 ± 27.13 | 0.050        |
|       | Motility (%) | 32.38 ± 18.28 | 41.86 ± 16.72 | 0.004        |
|       | Morphology (%) | 43.30 ± 18.77 | 50.71 ± 18.15 | 0.010        |
| II    | Volume (mL) | 3.40 ± 1.93   | 3.19 ± 1.37    | 0.370        |
|       | Total count (million/mL) | 18.04 ± 18.52 | 28.02 ± 35.51 | 0.046        |
|       | Motility (%) | 39.20 ± 16.80 | 45.93 ± 18.37 | 0.004        |
|       | Morphology (%) | 49.10 ± 16.50 | 47.23 ± 17.94 | 0.339        |
| III–IV| Volume (mL) | 3.33 ± 1.63   | 3.41 ± 1.20    | 0.809        |
|       | Total count (million/mL) | 15.04 ± 13.73 | 33.27 ± 51.88 | 0.054        |
|       | Motility (%) | 39.59 ± 18.51 | 41.82 ± 16.80 | 0.479        |
|       | Morphology (%) | 54.41 ± 18.49 | 53.14 ± 15.58 | 0.731        |

Spearman correlation analysis highlighted that pre-operative (rho = 0.233, \( p = 0.012 \)) and post-operative (rho = 0.189, \( p = 0.043 \)) volume was significantly correlated with BMI. However, other pre-operative and post-operative parameters (total count, motility, and morphology) did not correlate with BMI.

In patients with an age below 30 years and a lower BMI, the total count was increased from 20.21 ± 17.28 million/mL to 38.69 ± 56.55 million/mL (\( p = 0.041 \)), and this trend was also observed in the subgroup of cases with age under 30 years, low BMI, and grade II varicocele (\( n = \) eleven patients), with an increase from 8.36 ± 7.32 million/mL to 12.27 ± 8.16 million/mL (\( p = 0.046 \)). In patients with an age between 30 and 40 years and a higher BMI, the total count increased from 14.47 ± 9.90 million/mL.
to 24.73 ± 28.94 million/mL ($p = 0.045$). Subgroup analysis revealed that motility increased in the age group of 30–40 years with a higher BMI, and grade II varicocele ($n = $ six patients), from 29.17% ± 9.17% to 50.08% ± 20.10% ($p = 0.044$). In subjects with a lower BMI, motility increased after surgery from 37.15% ± 19.86% to 42.11% ± 19.85% ($p = 0.049$) (Table 5). Three men aged <30, 4 men aged between 30 and 40, and 3 patients aged between 40 and 49 had missing data from their charts, and subsequently were excluded from the analysis of semen parameters pre- and post-varicocelectomy according to the grade of the varicocele.

**Table 5.** Semen parameters pre- and post-varicocelectomy according to age and BMI.

| Group | Parameters | Pre-Operative | Post-Operative | $p$-Value |
|-------|------------|---------------|----------------|----------|
| Age < 30 (number of patients) | Volume (mL) | 4.33 ± 1.70 | 4.17 ± 1.40 | 0.002 |
| BMI ≥ 28.6 (20) | Total count (million/mL) | 16.42 ± 21.81 | 21.10 ± 15.52 | 0.258 |
| | Motility (%) | 39.0 ± 21.44 | 43.50 ± 16.47 | 0.243 |
| | Morphology (%) | 48.33 ± 23.38 | 65.83 ± 19.85 | 0.311 |
| BMI < 28.6 (29) | Volume (mL) | 2.86 ± 1.20 | 3.35 ± 1.72 | 0.112 |
| | Total count (million/mL) | 20.21 ± 17.28 | 38.69 ± 56.55 | 0.041 |
| | Grade II | 8.36 ± 7.32 | 12.27 ± 8.16 | 0.046 |
| | Motility (%) | 37.17 ± 17.72 | 43.79 ± 18.06 | 0.045 |
| | Morphology (%) | 52.00 ± 18.13 | 50.54 ± 21.20 | 0.810 |
| Age: 30–40 | Volume (mL) | 3.95 ± 1.93 | 3.61 ± 1.01 | 0.424 |
| BMI ≥ 28.6 (21) | Total count (million/mL) | 14.47 ± 9.90 | 24.73 ± 28.94 | 0.045 |
| | Motility (%) | 41.76 ± 18.06 | 46.90 ± 18.34 | 0.305 |
| | Grade II | 29.17 ± 9.17 | 50.08 ± 20.10 | 0.044 |
| | Morphology (%) | 52.44 ± 15.39 | 45.22 ± 15.39 | 0.142 |
| BMI < 28.6 (27) | Volume (mL) | 2.91 ± 1.46 | 2.98 ± 1.29 | 0.770 |
| | Total count (million/mL) | 11.85 ± 17.05 | 17.53 ± 22.51 | 0.179 |
| | Motility (%) | 37.15 ± 19.86 | 42.11 ± 19.85 | 0.049 |
| | Morphology (%) | 39.67 ± 23.38 | 39.56 ± 25.15 | 0.977 |
| Age: 40–49 | Volume (mL) | 3.44 ± 0.78 | 3.74 ± 1.40 | 0.538 |
| BMI ≥ 28.6 (12) | Total count (million/mL) | 15.87 ± 23.23 | 17.86 ± 19.18 | 0.814 |
| | Motility (%) | 39.83 ± 19.50 | 46.25 ± 22.07 | 0.211 |
| | Morphology (%) | 53.50 ± 10.49 | 54.90 ± 14.54 | 0.513 |
| BMI < 28.6 (4) | Volume (mL) | 4.62 ± 3.35 | 2.75 ± 1.19 | 0.180 |
| | Total count (million/mL) | 29.5 ± 19.62 | 43.75 ± 30.70 | 0.357 |
| | Motility (%) | 37.25 ± 17.97 | 42.50 ± 9.57 | 0.109 |
| | Morphology (%) | 39.25 ± 14.36 | 41.67 ± 23.63 | 0.999 |

High BMI: BMI ≥ 28.6, Low BMI: BMI < 28.6.

Out of 102 patients who were actively trying to conceive, the post-operative pregnancy rate after undergoing a sub-inguinal varicocelectomy was 52/102 (50.98%); further semen analysis, however, was not included in the study design. The remaining patients were either lost to follow-up or not married. There was no significant correlation between fertility and any of the improvements in sperm parameters mentioned above post-operatively. Moreover, there was no significant difference in fertility across the different age groups or varicocele grades.
4. Discussion

Our study found a significant improvement in the total sperm count and the motility of the sperm post-varicocelectomy across the entire cohort. This result is in concordance with previous studies (including meta-analysis) that have shown similar improvement [4,6,14–16]. In our study, subgroup analysis, younger patients, and lower grade of varicocele were associated with the post-operative increase of semen parameters. In addition, BMI was positively correlated with semen volume regardless of operation.

It is interesting to note that the statistically significant increase in total sperm count was only seen in the group of patients below 30 years of age. Other studies reported that total sperm count was decreased in varicocele patients, and that varicocelectomy improves total sperm counts [4,5]. Although the cut-off age was different, this result was in agreement with the conclusions of a study conducted in Austria, whereby younger patients benefit most from the procedure [6]. Unlike our results, this study revealed that patients showed increased total sperm count regardless of grades of varicocele. Our results also showed a significant increase in post-operative total sperm count in the grade I and II groups, although grade III patients showed the highest increased total sperm count with a borderline significance ($p = 0.054$). In our study, among patients in the group below 30 years, the total sperm count was increased after varicocelectomy only in the lower BMI group.

As for sperm motility, there was a significant increase in all three age groups. This result is in agreement with the results of meta-analyses [4,16]. However, those meta-analyses did not perform subgroup analysis. Meanwhile, in our research, the most significant increase of semen motility was shown in the third age group (40–49 years), with an 8.95% (from 34.61% to 43.56%) increase. This also agrees with another study, whereby the older aged population can still benefit from the procedure regarding sperm motility. However, that study grouped together patients with an age between 25 and 63 years [6]. Like total sperm count, grade III and IV patients did not significantly increase post-operative sperm motility.

In our study, the lower grades exhibited more improvement in semen motility and total counts after varicocelectomy. These results are in concordance with those described by Polito et al.’s study, where grade I varicoceles showed the most significant improvement in sperm density and motility [17]. However, their results were contradicted by those of Jungwirth et al., and Onozawa et al., which showed that the higher the grade of varicocele, the more significant the improvement in total sperm count and sperm density post-varicocelectomy [6,18]. Including our study, all studies had a small number of patients and did not adjust for other potential variables that improve semen parameters. Considering the relatively equal number of patients in each group [17], semen motility and total counts may improve more in lower grade varicocele, although more research is clearly needed to draw definite inferences.

There are several theories about the development of varicoceles, but the exact mechanisms remain to be elucidated. It is hypothesized that a “nutcracker effect”, or compression of the left renal vein, is pivotal in the pathogenesis of varicocele [19]. Low BMI patients, and decreased adipose tissue, especially between the superior mesenteric artery and aorta, prone affected patients to compression of the renal vein, which thus provokes development and recurrence of varicocele [11,20–22].

Cho et al. accumulated the data from 33 randomized control trials regarding the effect of varicocelectomy on pregnancy rate and the improvement of semen parameters as a potential first-line therapeutic option [8]. To recommend varicocelectomy as a standard of care, more data are needed to perform this treatment option for infertility with a high grade of evidence [23]. In line with this conservative statement, review articles show higher impotence rates in the treatment arm post-varicocelectomy, as opposed to the controls who did not undergo surgery [24–26].

It has been well established in the literature that increasing BMI decreases semen parameters, mainly sperm count, sperm concentration, and semen volume [27]. Our study showed that semen volume mainly decreases with increased BMI, and this is independent of varicocelectomy. An extensive review published by Guo et al. showed that semen volume is especially susceptible to BMI [27];
however, the reason is currently unknown and could have hormonal factors or biochemical causes that are yet to be revealed.

5. Conclusions

In conclusion, undergoing a varicocelectomy seems to improve the patient’s semen parameters, especially the count and the motility. Moreover, undergoing a varicocelectomy at a younger age might have the most significant impact on these parameters. The grade of the varicocele is also essential when it comes to treatment, as grades I and II show higher rates of improvement in semen parameters post varicocelectomy. However, our study showed that no correlation was observed between fertility and the increase in these parameters, requiring further studies with a larger sample size in the future, in order to obtain substantial and significant results.

Some challenges/limitations to our study include (1) incomplete data in the clinic charts, (2) no long-term follow up post-varicocelectomy in some cases, (3) small sample size, and (4) the absence of periodic spermograms postoperatively that would help in trending the changes of the parameters studied.

Author Contributions: R.A.G. and R.Z.E.-D. designed this study; R.A.G., R.Z.E.-D., M.B., J.B., S.A, and N.A.H. collected data; R.A.G. and J.Y.L. did the analysis; R.A.G., R.Z.E.-D., J.B., S.A., Y.L., S.H.H., J.W.Y., A.K., and J.I.S. wrote the first draft of the manuscript and gave critical comments on the manuscript draft. All authors had full access to all the study data. All authors reviewed, wrote, and approved the final version. The corresponding author had ultimate responsibility for the decision to submit for publication. All authors have read and agreed to the published version of the manuscript.

Funding: This research received no external funding

Conflicts of Interest: The authors declare no conflict of interest.
