NON-GENERICITY PHENOMENON IN SOME ORDERED FRAÏSSÉ CLASSES

KONSTANTIN SLUTSKY

Abstract. We show that every two-dimensional class of topological similarity, and hence every diagonal conjugacy class of pairs, is meager in the group of order preserving bijections of the rationals and in the group of automorphisms of the randomly ordered rational Urysohn space.

1. Introduction

The size of conjugacy classes (in the topological sense: dense, meager, comeager, etc.) in the groups of automorphisms of the Fraïssé limits has recently become an active area of research. This is partially due to the newly revealed connections between combinatorial properties of the Fraïssé classes and algebraic, topological, and dynamical properties of the groups of automorphisms of their limits. One of the most astonishing links was established by Kechris, Pestov and Todorcevic in [4] and displays close relationship between the Ramsey theory (a purely combinatorial area) and the extreme amenability (a classical dynamical notion).

Another reason for the interest in the size of conjugacy classes of Polish groups in general, and groups of automorphisms of Fraïssé limits in particular, comes from the special importance of some concrete groups, e.g., the group of automorphisms of the countable atomless Boolean algebra (which is isomorphic via the Stone’s theorem to the group of homeomorphisms of the Cantor space), the group of isometries of the rational Urysohn space, and the group of order preserving bijections of the rationals. The reader may consult [5] for details, examples, and a deep structural theory for the groups with large conjugacy classes.

In [9] J. K. Truss looked at different possible notions of genericity of conjugacy classes and discussed advantages of each. In general, conjugacy classes are objects that are difficult to understand, and the relation of conjugation may sometimes be very complicated (complete analytic). Motivated by the work of Truss, in this paper we look at a coarser equivalence relation than conjugation, namely at classes of topological similarity. They are much easier to work with and can be used to prove the non-genericity in some cases.

Let us recall the definition from [7].

Definition 1.1. Let $G$ be a topological group, an $n$-tuple $(g_1, \ldots, g_n) \in G^n$ is said to be topologically similar to an $n$-tuple $(f_1, \ldots, f_n) \in G^n$ if the map $F$ sending $g_i \mapsto f_i$ extends (necessarily uniquely) to a bi-continuous isomorphism between the groups generated by these tuples

$$F : \langle g_1, \ldots, g_n \rangle \to \langle f_1, \ldots, f_n \rangle.$$ 

We denote this relation by $E^n_{TS}$. 

1
There is another natural relation on the $n$-tuples in $G$, namely the relation of diagonal conjugation, i.e, $(g_1, \ldots, g_n)$ is conjugate to $(f_1, \ldots, f_n)$ if there is some $\alpha \in G$ such that

$$(\alpha g_1 \alpha^{-1}, \ldots, \alpha g_n \alpha^{-1}) = (f_1, \ldots, f_n).$$

More generally, if $G$ is a topological subgroup of $H$, then one can restrict the conjugacy relation in $H$ to $G$, i.e, say that an $n$-tuple $(g_1, \ldots, g_n) \in G^n$ conjugates in $H$ to an $n$-tuple $(f_1, \ldots, f_n) \in G^n$ if there is some $\beta \in H$ such that

$$(\beta g_1 \beta^{-1}, \ldots, \beta g_n \beta^{-1}) = (f_1, \ldots, f_n).$$

It is easy to see that this is an equivalence relation on $n$-tuples of $G$ and we denote it by $E^G_n$ (this relation also depends on $G$ and on the embedding of $G$ into $H$, but this information is usually clear from the context). The following proposition is obvious.

**Proposition 1.2.** Let $G$ be a topological group and $n \in \mathbb{N}$, then

(i) relation of topological similarity is an equivalence relation;

(ii) let $H$ be any topological group such that $G \leq H$ is a topological subgroup of it, then $E^H_n$ is finer (not necessarily strictly) than $E^n_{TS}$. In particular, $E^G_n$ is finer than $E^n_{TS}$.

Equivalence classes of topological similarity on $n$-tuples are called \textit{n-dimensional similarity classes}, in particular two-dimensional similarity class is a set of pairs.

Since conjugacy classes refine classes of topological similarity, if one wants to prove meagerness of the former, it suffices to prove meagerness of the latter (it suffices, but may be impossible, meagerness of conjugacy classes does not implies meagerness of classes of topological similarity). This sometimes turns out to be an easier task. For example, Rosendal in [7] developed this idea to find a simple proof of the del Junco’s result, that each conjugacy class of measure preserving automorphisms of the standard Lebesgue space is meager.

Hodkinson showed (see [9] for the details) that in the group of order preserving automorphisms of the rationals all conjugacy classes of pairs are meager (though it is known that there is a comeager one-dimensional conjugacy class in $\text{Aut}(\mathbb{Q})$). In this paper we strengthen this result and show that all two-dimensional classes of topological similarity are meager in this group.

The paper is organized as follows. In the second section we give a brief introduction to the theory of Fraïssé classes, which is the right context for the technique, developed in this paper. The third section is devoted to the strengthening of the Truss’s result on classes of diagonal conjugation in the rationals, in the fourth and fifth sections analogous theorem is proved for the group of order preserving isometries of the randomly ordered rational Urysohn space.

**Acknowledgment.** The author wants to thank Christian Rosendal for advising him during the process of writing this paper, for posing questions, that are covered here, and for helpful and very inspiring communication and comments. The author also thanks Slawomir Solecki and Ward Henson for helpful discussions.

### 2. Brief introduction to Fraïssé classes

In this section we give a short introduction to the theory of Fraïssé classes. In the next two sections we deal with two examples of them, so it is useful to keep in
mind this more general setting. The classical text on Fraïssé classes is a beautiful book by Hodges [3].

Let $L$ be a relational first order language. We use the standard notation: solid arrows correspond to “for all” quantifiers, and dashed arrows represent maps that “exist”.

**Definition 2.1.** Let $A$ and $B$ be two $L$-structures. A map $f : A \to B$ is called a **strong homomorphism** if for any $R \in L$ of arity $m$ and for any $x_1, \ldots, x_m \in A$

$$R^A x_1 \ldots x_m \iff R^B f(x_1) \ldots f(x_m).$$

The map is a **strong embedding** if it is an injective strong homomorphism.

**Definition 2.2.** Let $K$ be a class of finite $L$-structures. For $L$-structures $A$ and $B$ by $A \leq B$ we mean “$A$ strongly embeds into $B$”. $K$ is called a Fraïssé class if the following properties hold:

$(HP)$ If $A \leq B$ and $B \in K$ then $A \in K$;

$(JEP)$ For $A \in K$ and $B \in K$ there is some $C \in K$ such that $A \leq C$ and $B \leq C$;

$(AP)$ For $A \in K$, $B \in K$, $C \in K$ and embeddings $i : A \to B$, $j : A \to C$ there is $D \in K$ and embeddings $k : B \to D$, $l : C \to D$ such that $k \circ i = l \circ j$, i.e., the following diagram commutes

$$\begin{array}{ccc}
A & & B \\
\downarrow^i & & \downarrow^k \\
C & & D \\
\downarrow^j & & \downarrow^l \\
\end{array}$$

$(Inf)$ $K$ contains structures of arbitrarily high finite cardinality and has up to isomorphism only countably many structures.

Basic examples of Fraïssé classes are: finite sets, finite linear orders, finite graphs and finite metric spaces with rational distances (to satisfy $(Inf)$ condition). With a Fraïssé class $K$ one can associate its Fraïssé limit (which is unique up to an isomorphism).

**Definition 2.3.** Countably infinite structure $K$ is called a **Fraïssé limit** of the class $K$ if the following holds:

$(i)$ Finite substructures of $K$ up to isomorphism are exactly the elements of $K$;

$(ii)$ $K$ is ultrahomogeneous (that is any isomorphism between finite substructures of $K$ extends to a full automorphism of $K$).

Fraïssé limits of the above Fraïssé classes are: $\mathbb{N}$ — countably infinite set, $\mathbb{Q}$ — dense linear ordering without endpoints, $\mathbb{G}$ — random graph, $\mathbb{QU}$ — rational Urysohn space.

In the next section we deal with the simplest linearly ordered Fraïssé class: with the rationals $\mathbb{Q}$. The fourth and fifth sections are devoted to the case of the linearly ordered rational Urysohn space.
3. Topological Similarity Classes in the Groups $\text{Aut}(\mathbb{Q})$ and $\text{Homeo}^+([0,1])$

Let $\mathbb{Q}$ denote rational numbers viewed as a linearly ordered set. By an open interval $I = (a,b) \subset \mathbb{Q}$ we mean the set of rational numbers $\{c : a < c < b\} \subset \mathbb{Q}$. A closed interval $[a,b]$ also includes endpoints $a$ and $b$. If $I$ is a bounded interval (open or closed) $L(I)$ will denote its left endpoint and $R(I)$ will be its right endpoint. If $A \subset \mathbb{Q}$ is a finite subset, $\min(A)$ and $\max(A)$ will denote its minimal and maximal elements respectively.

Let $G$ denote the group $\text{Aut}(\mathbb{Q})$ of order preserving bijections of the rationals.

**Definition 3.1.** A partial isomorphism of $\mathbb{Q}$ is an order preserving bijection $p$ between finite subsets $A$ and $B$ of $\mathbb{Q}$.

It is a basic property of rationals (and, as mentioned earlier, of a Fra"iss"e limit in general) that each partial isomorphism can be extended (certainly, not uniquely) to a full automorphism.

Letters $p$ and $q$ (with possible sub- or superscripts) will denote partial isomorphisms; let $\text{dom}(p)$ be the domain of $p$, and $\text{ran}(p)$ be its range. If $I \subseteq \mathbb{Q}$ then $p|_I$ denotes restriction of $p$ on $I \cap \text{dom}(p)$; $F(p)$ will be the set of fixed points in the domain of $p$, i.e.,

$$F(p) = \{ c \in \text{dom}(p) : p(c) = c \}.$$

First we recall that $G$ is a Polish group (i.e., a separable completely metrizable topological group) in the topology given by the basic open sets $U(p) = \{ g \in G : g \text{ extends } p \}$, where $p$ is a partial isomorphism of $\mathbb{Q}$. Note that if $p$ and $q$ are two partial isomorphisms and $q$ extends $p$ then $U(q) \subseteq U(p)$; we will use this observation frequently. We denote the identity element of $G$ by $1$.

We use words generic and comeager as synonyms. For example, a property is generic in the group $G$ if the set of elements with this property is comeager in $G$.

Let $F(s,t)$ denote the free group on two generators: $s$ and $t$; elements of $F(s,t)$ are reduced words on the alphabet $\{ s,t,s^{-1},t^{-1} \}$. Every element $w \in F(s,t)$ has certain length associated to it, namely the length of the reduced word $w$. This length is denoted by $|w|$. If $u,v \in F(s,t)$ are words, we say that the word $uw \in F(s,t)$ is reduced if $|uw| = |u| + |v|$, that is there is no cancellation between $u$ and $v$.

If $w \in F(s,t)$ is a reduced word, $w = t^{n_k}s^{m_k} \cdots t^{n_1}s^{m_1}$, and $p$, $q$ are partial isomorphisms, then we can define a partial isomorphisms $w(p,q)$ by $w(p,q)(c) = q^{n_k}p^{m_k} \cdots q^{n_1}p^{m_1}(c)$, whenever the right-hand side is defined. The orbit of $c$ under $w(p,q)$ is by definition

$$\text{Orb}_{w(p,q)}(c) = \cup_{l=1}^k \{ p^{|\text{sign}(m_i)|}q^{n_{i-1}} \cdots p^{m_1}(c), q^{|\text{sign}(m_i)|}p^{m_1} \cdots p^{n_1}(c) : i = 0, \ldots, |m_l|, j = 0, \ldots, |n_l| \}.$$

We say that a word $w$ starts from the word $v$ if $w$ can be written as $w = vu$ for some word $u$, where $vu$ is reduced. Similarly, we say that $w$ ends in $v$ if there is a word $u$ such that $w = uv$, where $uv$ is reduced. On the one hand this is consistent with intuitive understanding of this notions for, say, left-to-right languages. On the other hand, we consider left actions, and then the end of the word acts first, i.e., if $w = st$ then $w(p,q)(c) = p(q(c))$. This may be a bit confusing, we apologize for that and emphasize this possible confusion.
Definition 3.2. Let $p$ be a partial isomorphism of $\mathbb{Q}$. An interval $(a, b) \subset \mathbb{Q}$ is called $p$-increasing if $a, b \in \text{dom}(p)$, $p(a) = a$, $p(b) = b$ and $p(c) > c$ for any $c \in \text{dom}(p) \cap (a, b)$. Definition of $p$-decreasing interval is analogous. Note that if $[a, b] \cap \text{dom}(p) = \{a, b\}$ and $p(a) = a$, $p(b) = b$ then the interval $(a, b)$ is both $p$-increasing and $p$-decreasing. An interval is $p$-monotone if it is either $p$-increasing or $p$-decreasing.

Definition 3.3. Let $p$ be a partial isomorphism. Let $\text{dom}(p) = \{a_0, \ldots, a_n\}$ and assume that $a_0 < \ldots < a_n$. We say that $p$ is informative if $p(a_0) = a_0$, $p(a_n) = a_n$ and there is a list $\{i_0, \ldots, i_r\}$ of indices such that

(i) $i_0 = 0$, $i_r = n$;
(ii) $a_{i_k} = p(a_{i_k})$ for $0 \leq k \leq r$;
(iii) for any $0 < k < r$ the interval $(a_{i_k}, a_{i_k+1})$ is $p$-monotone.

If $p$ is an informative partial isomorphism and $\text{dom}(p) = \{a_0, \ldots, a_n\}$ as above then we set

$$\text{Ess}(p) = (\text{dom}(p) \cup \text{ran}(p)) \setminus \{a_0, a_n\}$$

and refer to it as to the set of essential points of $p$.

Definition 3.4. A pair $(p, q)$ of partial isomorphisms is called piecewise elementary if the following holds

(i) $p$ and $q$ are informative;
(ii) $\min(\text{dom}(p)) = \min(\text{dom}(q))$,
(iii) $\max(\text{dom}(p)) = \max(\text{dom}(q))$.

If additionally $F(p) \cap F(q)$ has cardinality at most 2 (i.e., consists of the above minimum and maximum) then the pair $(p, q)$ is called elementary.

Let $(p, q)$ be a piecewise elementary pair, and $F(p) \cap F(q) = \{a_0, \ldots, a_n\}$ with $a_i < a_j$ for $i < j$. Set $I_j = [a_j, a_{j+1}]$, then $(p|_{I_j}, q|_{I_j})$ is elementary for any $0 \leq j < n$. Thus every piecewise elementary pair $(p, q)$ can be decomposed into finitely many elementary pairs.

The following obvious lemma partially explains the importance of piecewise elementary pairs.

Lemma 3.5. For any open $V \subseteq G \times G$ there is a piecewise elementary pair $(p, q)$ such that $U(p) \times U(q) \subseteq V$.

Definition 3.6. Let $(p, q)$ be an elementary pair. We say that a triple $(p', q', w)$ liberates $p$ in $(p, q)$, where $p'$ and $q'$ are partial isomorphisms that extend $p$ and $q$ respectively, and $w \in F(s, t)$ is a reduced word, if the following holds

(i) $p'$ and $q'$ are informative;
(ii) $\min(\text{dom}(p')) = \min(\text{dom}(p))$, $\min(\text{dom}(q')) = \min(\text{dom}(q))$;
(iii) $\max(\text{dom}(p')) = \max(\text{dom}(p))$, $\max(\text{dom}(p')) = \max(\text{dom}(p))$;
Similarly, we say that a triple \((p', q', w)\) liberates \(q\) in \((p, q)\) if the above holds with roles of \(p\) and \(q\) and \(s\) and \(t\) interchanged.

For a piecewise elementary pair \((p, q)\), we say that a triple \((p', q', w)\) liberates \(p\) [liberates \(q\)] in \((p, q)\) if

(i) \(\min(\text{dom}(p')) = \min(\text{dom}(p))\), \(\min(\text{dom}(q')) = \min(\text{dom}(q))\);
(ii) \(\max(\text{dom}(p')) = \max(\text{dom}(p))\), \(\max(\text{dom}(p')) = \max(\text{dom}(q))\);
(iii) for any interval \(I\), such that \((p|_I, q|_I)\) is elementary, the triple \((p'|_I, q'|_I, w)\)
liberates \(p|_I\) [liberates \(q|_I\)] in \((p|_I, q|_I)\).

Lemma 3.7. For any elementary pair \((p, q)\) there is a triple \((p', q', w)\) that liberates \(p\) [liberates \(q\)] in \((p, q)\).

Proof. We show the existence of a triple that liberates \(p\), the second clause then follows by symmetry.

Extending \(p\) and \(q\) if necessary, we may assume that

(i) \(\text{Ess}(p) \neq \emptyset\), \(\text{Ess}(q) \neq \emptyset\);
(ii) \(I_1, \ldots, I_k\) are all the (open) intervals of monotonicity for \(p\) and \(J_1, \ldots, J_k\) are all the (open) intervals of monotonicity for \(q\); we list them in the increasing order, i.e., \(I_i < I_{i+1}\), \(J_j < J_{j+1}\);
(iii) \(I_i \cap \text{dom}(p) \neq \emptyset\) and \(J_j \cap \text{dom}(q) \neq \emptyset\);
(iv) \(I_k \cap \text{dom}(p) = \emptyset\) and \(J_l \cap \text{dom}(q) = \emptyset\);
(v) \(L(I_k) > L(J_l)\).

Let \(\alpha = \min(\text{Ess}(p) \cup \text{Ess}(q))\). Then \(\alpha \in I_1 \cap J_1\) by (iii) (and in particular \(\alpha\) is not a fixed point of \(p\) or \(q\)). We first find an extension \(p_1\) of \(p\) and \(m_1 \in \mathbb{Z}\) such that \(p_1^{m_1}(\alpha)\) is defined and is “close enough” to the right endpoint of \(I_1\). “Close enough” exactly means the following. Since by assumptions \(R(I_1)\) is not fixed by \(q\) (because \((p, q)\) is elementary), there is some \(j_1\) such that \(R(I_1) \in J_{j_1}\) and we want \(p_1^{m_1}(\alpha) \in J_{j_1}\). Note that \(p_1\) is informative and has the same intervals of monotonicity as \(p\). At the second step we find extension \(q_1\) of \(q\) and \(n_1 \in \mathbb{Z}\) such that \(q_1^{n_1} p_1^{m_1}(\alpha)\) is defined and is “close enough” in the above sense to the right endpoint of \(J_{j_1}\). We proceed in this way and stop as soon as the image of \(\alpha\) reaches \(J_l\), i.e., we obtain extensions \(\bar{p}, \bar{q}\) of \(p\) and \(q\) and a word \(v = s^{n_1} s^{n_2} \ldots s^{n_l} v^{m_1}\) such that \(u(\bar{p}, \bar{q})(\alpha)\) is defined, lies in \(J_l\) and \(v(\bar{p}, \bar{q})(\alpha) \notin J_l\). Note that since we added to the domain of \(q\) only points of the orbit of \(\alpha\) under \(v\), this implies \(\text{dom}(\bar{q}) \cap J_l = \emptyset\). Also by induction \(\bar{p}\) and \(\bar{q}\) are informative with the same decomposition into intervals of monotonicity as for \(p\) and \(q\).

The following figure illustrates the construction (horizontal arrows indicate monotonicity of partial isomorphisms, bars stand for fixed points, the black dot is the minimal element \(\alpha\), and gray dots are its images under \(u\)): [Figure description]
We now take extension $\bar{p}', \bar{q}'$ of $\bar{p}$ and $\bar{q}$ such that
(i) $u(\bar{p}', \bar{q}')(c)$ is defined for every $c \in \text{Ess}(p) \cup \text{Ess}(q)$;
(ii) $\bar{p}'$ and $\bar{q}'$ are informative with the same decomposition into intervals of monotonicity as for $\bar{p}$ and $\bar{q}$;
(iii) minimum and maximum of the domains of $\bar{p}'$ and $\bar{q}'$ are equal to the minimum and maximum of the domains of $\bar{p}$ and $\bar{q}$;
(iv) $\bar{q}'$ is increasing on $J_1$ (this is possible since $J_1 \cap \text{dom}(\bar{q}) = \emptyset$).

Set $p' = \bar{p}'$. Finally extending $q'$ to $q''$ we can find $M \in \mathbb{N}$ such that
$$q''M u(p', q')(\alpha) > \max(\text{Ess}(p')).$$ And so let $w = \alpha^M u$, then $(p', q', w)$ liberates $p$ in $(p, q)$. \qed

Remark 3.8. In the lemma above we started our construction from applying a power of $p$, but we likewise could start it from applying a power of $q$.

Remark 3.9. We view rationals as a dense linear ordering without endpoints. But note that if would have a usual metric on $Q$ then the above construction gives us $p', q'$, and $w$ such that $w(p', q')(\alpha)$ is as close in this metric to the endpoint $\max(\text{dom}(p))$ as one wants. We will use this observation later.

Lemma 3.10. For any elementary pair $(p, q)$ and any word $u$ there is a word $v$, and partial isomorphisms $p'$ and $q'$ such that the triple $(p', q', vu)$ liberates $q$ in $(p, q)$ and $|vu| = |v| + |u|$ (i.e., no cancellation between $v$ and $u$ happens).

Proof. First we take extensions $p_1$ and $q_1$ of $p$ and $q$ respectively such that $u(p_1, q_1)(c)$ is defined for any $c \in \text{dom}(p) \cup \text{dom}(q)$. $(p_1, q_1)$ is elementary and
$$\min(\text{dom}(p_1)) = \min(\text{dom}(p)) = \min(\text{dom}(q)) = \min(\text{dom}(q_1)),$$
$$\max(\text{dom}(p_1)) = \max(\text{dom}(p)) = \max(\text{dom}(q)) = \max(\text{dom}(q_1)).$$

By Lemma 3.7 one can find a word $v$ and extensions $p', q'$ of $p_1$, $q_1$ such that $(p', q', v)$ liberates $p_1$ in $(p_1, q_1)$. By Remark 3.8 we may also assume that there is no cancellation in $vu$. Then $(p', q', vu)$ liberates $p$ in $(p, q)$. \qed

Lemma 3.11. Let $(p, q)$ be a piecewise elementary pair and assume a triple $(p', q', w)$ liberates $q$ in $(p, q)$. Let $u = l^n v$, $|u| = s^m v$ be a reduced word such that $uv$ is irreducible. Then there is a triple $(p'', q'', uw)$ that liberates $p$ liberates $q$ in $(p, q)$. Moreover, one can take $p''$ to be an extension of $p'$ and $q''$ to be an extension of $q'$.

Proof. By the definition of liberation for piecewise elementary pairs it is enough to prove the statement for elementary triples only. So assume $(p, q)$ is elementary. Since $w$ liberates $p$ in $(p, q)$ it has to start with a non-zero power $l$ of $t$,
We claim that each \( B \) (there is a sequence of reduced words). Take an enumeration

\[ p_1, p_2, \ldots \]

Proof. Density follows from Lemma 3.13. Theorem 3.15. Each two-dimensional topological similarity class in \( G \) is meager.

Lemma 3.12. Let \((p,q)\) be a piecewise elementary pair and \( u \in F(s,t) \). Then there is a triple \((p', q', w)\) that liberates \( p' \) in \((p,q)\) and such that \(w = vu\) is reduced.

Proof. We prove the statement by induction on the number of elementary components of \((p,q)\). Lemma 3.10 covers the base of induction. Assume we have proved the lemma for \( r \)-many elementary components and inductively constructed a triple \((p_r, q_r, w_r)\) that liberates \( p_r \) in \((p_r, q_r)\), where \( p_r \) and \( q_r \) are restrictions of \( p \) and \( q \) onto the first \( r \) many elementary components. Consider the \( r + 1 \) elementary component of \((p,q)\). By Lemma 3.11 and by the base of induction there is a word \( w_{r+1} = v_{r+1}w_r \) and extensions \( \tilde{p}_{r+1}, \tilde{q}_{r+1} \) of \( p_r \) and \( q_r \) such that \((\tilde{p}_{r+1}, \tilde{q}_{r+1}, w_{r+1})\) liberates \( p_{r+1} \) in \((p_{r+1}, q_{r+1})\). By Remark 3.8 we may assume that \( v_{r+1}w_r \) is reduced. This proves the step of induction and hence the lemma.

Lemma 3.13. For any pair \((p,q)\) of partial isomorphisms and any word \( u \in F(s,t) \) there are extensions \( p' \) and \( q' \) of \( p \) and \( q \) respectively and a reduced word \( w = vu \) such that \( w(p', q')(c) = c \) for any \( c \in \text{dom}(p) \cup \text{dom}(q) \).

Proof. By Lemma 3.5 it is enough to prove the statement for a piecewise elementary pair \((p,q)\). By Lemma 3.12 we can find extensions \( \tilde{p}, \tilde{q} \) and a word \( v \) such that \((\tilde{p}, \tilde{q}, vu)\) liberates \( p \) in \((p,q)\). By the definition of liberation we can now extend \( \tilde{p} \) to \( p' \) by declaring

\[ p'(c) = c, \text{ for any } c \in vu(\tilde{p}, \tilde{q})(\text{Ess}(p) \cup \text{Ess}(q)). \]

Now set \( q' = \tilde{q} \) and \( w = u^{-1}v^{-1}svu \). Then \( w(p', q')(c) = c \) for any \( c \in \text{dom}(p) \cup \text{dom}(q) \).

Lemma 3.14. Fix a sequence \(\{u_k\}\) of reduced words. For a generic \((f,g) \in G \times G\) there is a sequence of reduced words \(w_k = v_k u_k\) such that \(w_k(f,g) \to 1\).

Proof. Take an enumeration \(\{c_i\} = \mathbb{Q}\) of the rationals. Let

\[ B_n^k = \{(f,g) \in G \times G : \exists w = v_k u_k \text{ reduced and } w(f,g)(c_i) = c_i \text{ for } 0 \leq i \leq n\}. \]

We claim that each \( B_n^k \) is dense and open. Indeed, assume for a certain \( n \) one has \((f,g) \in B_n^k \). This is witnessed by a word \( w \). Set

\[ D = \bigcup_{i=0}^n \text{Orb}_w(f,g)(c_i) \]

and let \( p = f|_D, q = g|_D \). Then \((f,g) \in U(p) \times U(q) \subseteq B_n^k \) and so \( B_n^k \) is open. Density follows from Lemma 3.13.

Now by Baire theorem \( \cap_{n,k} B_n^k \) is a dense \( G_\delta \). The lemma follows.

Theorem 3.15. Each two-dimensional topological similarity class in \( G \) is meager.
Proof. Assume towards the contradiction that there is a pair \((f_1, g_1) \in G \times G\) that has a non-meager class of topological similarity. Then by Lemma 3.14 there must be a sequence \(w_n = v_n t^n s^n\) of reduced words such that \((f_1, g_1)\) converges to the identity along this sequence (we apply Lemma 3.14 for the sequence \(u_k = t^k s^k\)).

Take and fix \(a \in \mathbb{Q}\). Set

\[ F_a = \{ (f, g) \in G \times G : f(a) = g(a) \}. \]

Let

\[ C_n = \{ (x, y) \in G \times G : \exists m > n \ w_m(x, y)(a) \neq a \}. \]

Then \(C_n\) is open and dense in \((G \times G) \setminus F_a\). To see density take a basic open set \(U(p) \times U(q) \subseteq (G \times G) \setminus F_a\) and assume \(p(a) \neq a\) (the case when \(p(a) = a\), but \(q(a) \neq a\) is similar). For some \(k > n\) \(p^k(a)\) is not in the domain of \(p\). Thus there are infinitely many values that \(f \in U(p)\) may attain at \(f^{k-1}(a)\), and so (by induction) there are infinitely many values that \(w_k(f, g)(a)\) may attain for a pair \((f, g) \in U(p) \times U(q)\). Hence for some \((f, g)\) one has \(w_k(f, g)(a) \neq a\). And so \(C_n\) is dense in \((G \times G) \setminus F_a\). An application of Baire theorem shows that \(\cap C_n\) is a dense \(G_δ\) and so for a generic \((f, g) \in (G \times G) \setminus F_a\) one has \(w_n(f, g)(a) \not\rightarrow a\). Since \(\bigcup_d (G \times G) \setminus F_a = (G \times G) \setminus \{1 \times 1\}\) we get a contradiction with the assumption that \(w_n(f_1, g_1) \rightarrow 1\) and that the class of topological similarity of \((f_1, g_1)\) is non-meager.

**Homeomorphisms of the unit interval.** We now turn to the group of homeomorphisms of the unit interval. This is a Polish group in the natural topology, given by the basic open sets:

\[ U(f; a_1, \ldots, a_n; \varepsilon) = \{ g \in \text{Homeo}(0, 1) : |g(a_i) - f(a_i)| < \varepsilon \}. \]

We may write this neighborhood as \(U(p; \varepsilon)\), where \(p = f|_{\{a_0, \ldots, a_n\}}\) is a partial isomorphism. Since \(\mathbb{Q}\) is dense in \([0, 1]\), we may assume that \(p\) is a partial isomorphism of the rationals: this will give us a base of open sets.

This group \(\text{Homeo}(0, 1)\) has a normal subgroup of index 2, namely the subgroup \(\text{Homeo}^+(0, 1)\) of order preserving homeomorphisms. Let \(H = \text{Homeo}^+(0, 1)\), then \(\text{Aut}(\mathbb{Q}) = G\) naturally embeds into \(H\) (this embedding is a continuous injective homomorphism, its inverse, though, is not continuous), and the image of \(G\) under this embedding is dense in \(H\).

**Theorem 3.16.** Every two-dimensional class of topological similarity in \(H\) is meager.

**Proof.** We imitate the proof of Theorem 3.15. Let \(\{x_m\}\) be an enumeration of the rationals \(\mathbb{Q} \cap [0, 1]\), then \(\{x_m\}\) is dense in \([0, 1]\). Set

\[ A_{m,n} = \{ f \in H : |f(x_m) - x_m| > 1/n \text{ and } |f^{-1}(x_m) - x_m| > 1/n \}, \]

\[ B_{m,n} = \{ (f, g) \in H \times H : f \in A_{m,n} \text{ or } g \in A_{m,n} \}. \]

Note that \(B_{m,n}\) is open for every \(m\) and \(n\). Then \(\bigcup_{m,n} B_{m,n} = H \times H \setminus \{(1, 1)\}\) and so it is enough to prove that each two-dimensional class of topological similarity is meager in each of \(B_{m,n}\).

Let \(u_k\) be a sequence of words such that for every piecewise elementary pair \((p, q)\) (here \(p\) and \(q\) are partial isomorphisms of the rationals, like before) there are infinitely many \(k\) such that for some \(p_k', q_k'\) \((p_k', q_k', u_k)\) liberates \(p\) in \((p, q)\). Then by Lemma 3.14 for a generic pair \((f, g) \in G \times G\) there is a sequence of reduced
words \( w_k = v_k u_k \) such that \( w_k(f, g) \to 1 \). This implies that for a generic pair \((f, g) \in H \times H\) there is a sequence \( w_k \) as above (because the topology in \( H \) is coarser than in \( G \)). If there is a non-meager two-dimensional class of topological similarity then there is a sequence of reduced words \( \{w_k\} \) (for some \( \{v_k\} \)) such that the set of pairs \((f_1, g_1) \in H \times H\) that converges to the identity along \( w_k \) is non-meager.

Fix now \( m, n \) and a sequence of reduced words \( w_k = v_k u_k \). Set

\[
C_k = \{(f, g) \in H \times H : \exists K > k \ |w_K(f, g)(x_m) - x_m| > 1/2n\}.
\]

Each \( C_k \) is open, we claim that it is also dense in \( B_{m,n} \). Let \( V \subseteq B_{m,n} \) be an open set. Without loss of generality we may assume that \( V = U(p; \varepsilon_1) \times U(q; \varepsilon_2) \), where \( p \) and \( q \) are partial isomorphisms of the rationals. Let

\[
\delta = \min\{|x_m - c| : c \in F(p) \cap F(q)\} > 1/n.
\]

Then there is \( K > k \) and \( p', q' \) such that \((p', q', u_K)\) liberates \( p \) in \((p, q)\). Now repeat the proof of Lemma 3.11 and use Remark 3.9 to get \( p'', q'' \) that extend \( p' \) and \( q' \) and such that \(|w_K(p'', q'')(x_m) - x_m| \geq 1/2\delta\). Hence each \( C_k \) is dense in \( B_{m,n} \). Now by Baire theorem the intersection \( \cap_k C_k \) is a dense \( G_\delta \) in \( B_{m,n} \) and thus for any specific sequence \( w_k \) the set of elements \((f_1, g_1) \in H \times H\) that converges to the identity along this sequence is meager in \( B_{m,n} \). Finally we showed that each two-dimensional topological similarity class is meager in \( B_{m,n} \) for any \( m, n \) and so is in \( H \times H \).

\[
\square
\]

4. Extensions of Partial Isometries

In this section we prove several results, that will be used later, when dealing with the randomly ordered Urysohn space. But we believe that some of the theorems below are of independent interest for understanding the group of isometries of the Urysohn space.

We remind that the Urysohn space \( U \) is a complete separable metric space, that is uniquely characterized by the following properties:

- Every finite metric space can be isometrically embedded into \( U \);
- \( U \) is ultrahomogeneous, that is each partial isometry between finite subsets of \( U \) extends to a full isometry of \( U \).

There is a rational counterpart \( \mathbb{Q}U \) of the Urysohn space. It is called rational Urysohn space. This is a countable metric space with rational distances, characterized by similar properties:

- Every finite metric space with rational distances can be isometrically embedded into \( \mathbb{Q}U \);
- \( \mathbb{Q}U \) is ultrahomogeneous.

Groups of isometries \( \text{Iso}(U) \) and \( \text{Iso}(\mathbb{Q}U) \) of these spaces are Polish groups when endowed with the topology of pointwise convergence (for this \( \mathbb{Q}U \) is viewed as a discrete topological space).

**Definition 4.1.** Let \((A, d)\) be a finite metric space with at least two elements. The **density** of \( A \) is denoted by \( D(A) \) and is the minimal distance between two distinct points in \( A \):

\[
D(A) = \min\{d(x, y) : x, y \in A, x \neq y\}.
\]
Definition 4.2. An ordered metric space is a triple \((A, d, <)\), where \(d\) is a metric on \(A\) and \(<\) is a linear ordering on \(A\).

Definition 4.3. A partial isometry or partial isomorphism of a metric space \(C\) is an isometry \(p : A \to B\) between finite subspaces \(A, B \subseteq C\). A partial isomorphism of and ordered metric space is a partial isometry of the metric space that also preserves the ordering on its domain.

Definition 4.4. Let \(p\) be a partial isometry of a metric space. Then we let \(\text{dom}(p)\) to denote the domain of \(p\) and \(\text{ran}(p)\) to denote its range. A point \(x \in \text{dom}(p)\) is called periodic if there is a natural number \(n > 0\) such that
\[
x, p(x), \ldots, p^n(x) \in \text{dom}(p) \quad \text{and} \quad p^n(x) = x.
\]
The set of periodic points is denoted by \(Z(p)\). A point \(x \in \text{dom}(p)\) is called fixed if \(p(x) = x\) and the set of fixed points is denoted by \(F(p)\).

In this section we deal mostly with the classical Urysohn space, but some of the results will be later applied to the randomly ordered rational Urysohn space. The following proposition will let us do that.

Proposition 4.5. Let \(A\) be a finite ordered metric space, let \(p\) be a partial isomorphism of \(A\). Let \(B\) be a finite metric space (with no ordering) and let \(q\) be a partial isometry of \(B\) with \(Z(q) = F(q)\). Suppose that \(A \subseteq B\) as metric spaces and \(q\) extends \(p\). If
\[
\forall x \in \text{dom}(q) \ q(x) \in A \iff x \in \text{dom}(p)
\]
then there is a linear ordering on \(B\) that extends an ordering on \(A\) and such that \(q\) becomes a partial isomorphism of an ordered metric space \(B\).

Proof. We prove the statement by induction on \(|B \setminus A|\). If \(A = B\) the statement is obvious. For inductive step we consider two cases.

Case 1. There is some \(x \in A\) such that \(x \in \text{dom}(q)\) but \(x \not\in \text{dom}(p)\). Then by assumption \(q(x) \in B \setminus A\). Extend now a linear ordering on \(A\) to a partial ordering on \(A \cup \{q(x)\}\) by declaring for \(y \in A\)
\[
\begin{align*}
q(x) < y & \iff \exists z \in \text{dom}(p) \ (p(z) \leq y) \land (x < z), \\
y < q(x) & \iff \exists z \in \text{dom}(p) \ (y \leq p(z)) \land (z < x).
\end{align*}
\]
It is straightforward to check that this relation is indeed a partial ordering on \(A \cup \{q(x)\}\). Extend this partial ordering to a linear ordering on \(A \cup \{q(x)\}\) in any way. Then \(q\) is a partial isomorphism of \(A \cup \{q(x)\}\) and we apply the induction.

Case 2. Assume the opposite to the first case happens. Then \(q|_{A} = p\). Take any \(x \in \text{dom}(q) \setminus A\) (if there is no such \(x\) then \(\text{dom}(p) = \text{dom}(q)\) and the statement is obvious). Assume first that \(x\) is not a fixed point of \(q\). Then define a linear ordering on \(A \cup \{x, q(x)\}\) by declaring
\[
\forall y \in A \ (y < x) \land (y < q(x)) \land (x < q(x)).
\]
Then \(q\) is a partial isomorphism of \(A \cup \{x, q(x)\}\) and we can apply the induction hypothesis. If \(x\) was a fixed point then we declare
\[
\forall y \in A \ (y < x),
\]
and, again, induction does the rest. □
Lemma 4.9. Let \( x \in B \) extends Orb disjoint over \( A \). There exist a finite metric space \( A \) be given. There exist a finite metric space \( D = B \ast_A C \) of metric spaces as follows: substituting \( B \) and \( C \) by their isomorphic copies we may assume that \( B \cap C = A \), set \( D = B \cup C \) and define the metric \( d_D \) by:

\[
d_D(x, y) = \begin{cases} 
    d_B(x, y) & \text{if } x, y \in B, \\
    d_C(x, y) & \text{if } x, y \in C, \\
    \min\{d_B(x, z) + d_C(z, y)\} & \text{otherwise.}
\end{cases}
\]

Note that the first and the second clauses agree for \( x, y \in A \).

If \( A \) is empty then we set \( R = \text{diam}(B) + \text{diam}(C), D = B \cup C \) and

\[
d_D(x, y) = \begin{cases} 
    d_B(x, y) & \text{if } x, y \in B, \\
    d_C(x, y) & \text{if } x, y \in C, \\
    R & \text{otherwise.}
\end{cases}
\]

The core of our arguments will be the following seminal result due to Sławomir Solecki established in 2005, see [8]. The second item is slightly modified compared to the original statement, but the modification follows from the proof in [8] without any additional work.

Theorem 4.7 (Solecki). Let a finite metric space \( A \) and a partial isometry \( p \) of \( A \) be given. There exist a finite metric space \( B \) with \( A \subseteq B \) as metric spaces, an isometry \( \bar{p} \) of \( B \) extending \( p \), and a natural number \( M \) such that

(i) \( \bar{p}^{2M} = 1_B \);

(ii) if \( a \in A \) is aperiodic then \( \bar{p}^j(a) \neq a \) for \( 0 < j < 2M \), and moreover for any \( 0 < j < 2M \) \( \bar{p}^j(a) \in A \) iff \( \bar{p}^{-1}(a) \in \text{dom}(p) \);

(iii) \( A \subseteq \bar{p}^M(A) \) is the free amalgam of \( A \) and \( \bar{p}^M(A) \) over \( (Z(p), \text{id}_{Z(p)}, \bar{p}^M|_{Z(p)}) \).

Moreover, the distances in \( B \) may be taken from the additive semigroup generated by the distances in \( A \).

Definition 4.8. Let \( A, B, C \) be metric spaces and let \( C \) be embedded into \( A \) and \( B \). We say that \( B \) extends \( A \) over \( C \) if there exist and embedding \( i : A \to B \) such that the following diagram commutes:

\[
\begin{array}{ccc}
A & \xrightarrow{i} & B \\
\downarrow & & \downarrow \\
C & \xrightarrow{i} & B
\end{array}
\]

We say that \( A \) and \( B \) are disjoint over \( C \) if neither \( B \) extends \( A \) over \( C \) nor \( A \) extends \( B \) over \( C \).

Lemma 4.9. Let \( A \) be a finite metric space, let \( p \) be a partial isometry of \( A \), let \( x \in \text{dom}(p) \) be such that \( x \notin F(p) \) (i.e., \( p(x) \neq x \)). Then there are metric spaces \( A_1 \) and \( A_2 \) that both extend \( A \): \( A \subseteq A_1 \) and \( A \subseteq A_2 \), and partial isometries \( p_1 \) of \( A_1 \) and \( p_2 \) of \( A_2 \) that both extend \( p \) and such that \( \text{Orb}_{p_1}(x) \) and \( \text{Orb}_{p_2}(x) \) are disjoint over \( \text{Orb}_p(x) \).

Moreover, one can assume that

\[
Z(p_1) = Z(p) = Z(p_2),
\]

\[
\forall x \in \text{dom}(p_1) \ p_1(x) \in A \iff x \in \text{dom}(p),
\]

\[
\forall x \in \text{dom}(p_2) \ p_2(x) \in A \iff x \in \text{dom}(p),
\]

\[
\forall x \in \text{dom}(p_1) \ p_2(x) \in A \iff x \in \text{dom}(p),
\]
\[\forall x \in \text{dom}(p_2) \ p_2(x) = A \implies x \in \text{dom}(p).\]

**Proof.** Apply Theorem 4.7 to get a full isometry \(\tilde{p}\) of a finite metric space \(B\) that extends \(p\) and a natural number \(M\). Set

\[\tilde{A} = A \cup \tilde{p}(A) \cup \ldots \cup \tilde{p}^{2M-1}(A) \cup \{y\},\]

where \(y\) is a new point, i.e., a point not in \(B\). Let \(\delta = D(A)\) denote the density of \(A\) and fix an \(\varepsilon > 0\) such that \(\varepsilon \leq 2\delta\). We turn \(\tilde{A}\) into a metric space by defining the distance between \(a, b \in \tilde{A}\), \(a \neq b\) as follows.

\[d_{\tilde{A}}(a, b) = \begin{cases} 
  d_B(a, b) & \text{if } a \neq y \text{ and } b \neq y, \\
  d_B(a, x) & \text{if } a \neq x \text{ and } b = y, \\
  d_B(b, x) & \text{if } a = y \text{ and } b \neq x, \\
  \varepsilon & \text{if } \{a, b\} = \{x, y\}.
\end{cases}\]

We claim that \((\tilde{A}, d_{\tilde{A}})\) is a metric space. We have to check the triangle inequality (other conditions are obviously fulfilled). For this note that both \(\tilde{A} \setminus \{y\}\) and \(\tilde{A} \setminus \{x\}\) are isometrically embeddable into \(B\), where the triangle inequality is known to be satisfied. So one needs to prove two claims.

**Claim 1.** For any \(z \in \tilde{A}\)

\[d_{\tilde{A}}(x, y) \leq d_{\tilde{A}}(x, z) + d_{\tilde{A}}(z, y).\]

If \(z \in \{x, y\}\) then the statement is obvious. If \(z \notin \{x, y\}\) then \(d_{\tilde{A}}(x, z) + d_{\tilde{A}}(z, y) \geq 2\delta\) and \(d_{\tilde{A}}(x, y) = \varepsilon \leq 2\delta\) and Claim 1 follows.

**Claim 2.** For any \(z \in \tilde{A}\)

\[d_{\tilde{A}}(x, z) \leq d_{\tilde{A}}(x, y) + d_{\tilde{A}}(y, z), \quad d_{\tilde{A}}(z, x) \leq d_{\tilde{A}}(z, y) + d_{\tilde{A}}(y, x).\]

Note that for \(z \notin \{x, y\}\) one has \(d_{\tilde{A}}(y, z) = d_{\tilde{A}}(x, z)\). From this both inequalities follow immediately.

So \(\tilde{A}\) is a metric space. We denote it by \(\tilde{A}(\varepsilon)\) to signify the dependence on epsilon. Define a partial isometry \(\tilde{p}\) on \(\tilde{A}(\varepsilon)\) by

\[\tilde{p}(x) = \tilde{p}(x),\]

whenever \(x \in \tilde{A}\) and \(\tilde{p}(x) \in \tilde{A}\); and \(\tilde{p}(\tilde{p}^{2M-1}(x)) = y\). It is straightforward to check that \(\tilde{p}\) is indeed a partial isometry. Now the construction of two extensions that are disjoint over \(\text{Orb}_p(x)\) is easy. Take, for example, two different \(\varepsilon_1 \leq 2\delta, \varepsilon_2 \leq 2\delta, \varepsilon_1 \neq \varepsilon_2\) such that

\[\varepsilon_i \notin \{d_B(x_1, x_2) : x_1, x_2 \in B\}\]

let \((A_i, p_i) = (\tilde{A}(\varepsilon_i), \tilde{p})\). Then \(\text{Orb}_{p_1}(x)\) and \(\text{Orb}_{p_2}(x)\) are disjoint over \(\text{Orb}_p(x)\).

The main power of Theorem 4.7 is the explicit construction of an extension of a partial isometry to a full isometry of a finite metric space. Moreover, this extension is as independent as possible. For our purposes we need only an extension to a partial isomorphism, but we want to keep the independence. Let us state explicitly a corollary of the theorem that keeps all we need.

**Corollary 4.10.** For any finite metric space \(A\) and a partial isometry \(p\) there is finite metric space \(C\), a partial isometry \(p_1\) of \(C\), which is an extension of \(p\), and a natural number \(M\) such that
Proof. Let the distances in Theorem 4.12. Moreover, the distances in \( B \) requirements of the statement. Let \( x \in \text{dom}(p_1) \)

\[ p_1(x) \in A \iff x \in \text{dom}(p). \]

Moreover, the distances in \( C \) are taken from the additive semigroup generated by the distances in \( A \), and hence the density is preserved \( D(C) = D(A) \).

\[ \text{Proof.} \text{ Apply Theorem 4.7 to } A \text{ and } p \text{ to get a metric space } B, \text{ a full isometry } \bar{p} \text{ of } B \text{ and a natural number } M. \text{ Now set} \]

\[ C = A \cup \bar{p}(A) \cup \ldots \bar{p}^M(A), \]

and \( p_1 = \bar{p}|_{A \cup \bar{p}(A) \cup \ldots \bar{p}^M(A)} \). It is trivial to check that such a \( C \) and \( p_1 \) satisfy the conditions. □

**Definition 4.11.** Let \( (M, d) \) be a metric space, let \( x, y \in M \). We say that the distance \( d(x, y) \) passes through a point \( z \in M \) if

\[ d(x, y) = d(x, z) + d(z, y). \]

We are going to apply Corollary 4.10 to partial isometries that also preserve an ordering. That is why we impose additional assumption: all periodic points are fixed points, i.e., \( Z(p) = F(p) \).

**Theorem 4.12.** Let \( A \) be a finite metric space. Let \( p \) and \( q \) be two partial isometries of \( A \) such that \( Z(p) = F(p) \) and \( Z(q) = F(q) \). Suppose \( F(p) \cap F(q) \neq \emptyset \). Then there are finite metric space \( B \), extensions \( \bar{p}, \bar{q} \) of \( p \) and \( q \) respectively (these extensions are partial isometries of \( B \)) and an element \( w = t^K v \in F(s, t), K \neq 0 \) such that

\[ (i) \ Z(\bar{p}) = Z(p) \; (= F(p)), \; Z(\bar{q}) = Z(q) \; (= F(q)); \]

\[ (ii) \ \text{dom}(\bar{p}) \cup w(\bar{p}, \bar{q})(A) \; \text{is the free amalgam of } \text{dom}(\bar{p}) \text{ and } w(\bar{p}, \bar{q})(A) \; \text{over } F(p) \cap F(q). \]

Moreover, the distances in \( B \) are taken from the additive semigroup generated by the distances in \( A \), and hence \( D(\text{dom}(\bar{p}) \cup A) = D(A), D(\text{dom}(\bar{q}) \cup A) = D(A) \).

\[ \text{Proof.} \text{ Let } N = \left\lceil \frac{2\text{diam}(A)}{D(A)} \right\rceil. \]

Define inductively the sequence of elements \( w_k \in F(s, t) \), extensions \( \bar{p}_k, \bar{q}_k \) and metric spaces \( A_k \) as follows:

**Step 0:** Let \( \bar{p}_0 = p, \bar{q}_0 = q, w_0 = \text{empty word}, A_0 = A; \)

**Step k:** If \( k \) is odd then apply Corollary 4.10 to \( \bar{p}_{k-1} \) and \( A_{k-1} \) to get \( \bar{p}_k \) and \( M_k; \) set \( \bar{q}_k = \bar{q}_{k-1}, w_k = s^{M_k} w_{k-1}, A_k = A_{k-1} \cup \text{dom}(\bar{p}_k) \cup \text{ran}(\bar{p}_k). \)

If \( k \) is even do the same thing with roles of \( p \) and \( q \) interchanged.

We claim that \( \bar{p} = \bar{p}_{2N+2}, \bar{q} = \bar{q}_{2N+2}, B = A_{2N+2}, \) and \( w = w_{2N+2} \) fulfill the requirements of the statement. Let \( d \) denote the metric on \( B \). It is obvious that \( F(\bar{p}) = F(p) \) and \( F(\bar{q}) = F(q) \) (this is given by Corollary 4.10 at each stage). The moreover part is also obvious, since it is fulfilled at every step of the construction. It remains to show that for any \( x \in w(\bar{p}, \bar{q})(A) \) and any \( y \in \text{dom}(\bar{p}) \) one has

\[ d(x, y) = \min\{d(x, z) + d(z, y) : z \in F(p) \cap F(q)\}. \quad (1) \]
Note that by the last step of the construction for any $x \in w(\bar{\rho}, \bar{q})(A)$ and $y \in \text{dom}(\bar{p})$ we have

$$d(x, y) = \min \{d(x, z) + d(z, y) : z \in F(q)\}.$$  

We first prove several claims.

**Claim 1.** It is enough to show that (1) holds for all $x \in w(\bar{\rho}, \bar{q})(A)$ and $y \in F(q)$.

**Proof of Claim 1.** Assume (1) holds for all $x \in w(\bar{\rho}, \bar{q})(A)$ and $y \in F(q)$. Let $y' \in \text{dom}(\bar{p})$, then for some $c \in F(q)$

$$d(x, y') = d(x, c) + d(c, y') = \min \{d(x, e) + d(e, y') : e \in F(q)\}.$$  

By assumptions of the claim we get

$$d(x, y') = d(x, z) + d(z, c) + d(c, y') \geq d(x, z) + d(z, y'),$$

for some $z \in F(p) \cap F(q)$; and so, by (2),

$$d(x, y') = d(x, z) + d(z, y').$$

This proves the claim.

Let $w_i(c)$ denote $w_i(\bar{p}, \bar{q}_i)(c)$.

**Claim 2.** Let $x \in F(p) \cup F(q)$, $c \in A$ and suppose that for some $z \in F(p) \cap F(q)$ and for some $i$ the distance between $w_i(c)$ and $x$ passes through $z$. Then for any $j \geq i$ the distance between $w_j(c)$ and $x$ passes through the same point $z$.

**Proof of Claim 2.** This follows by induction. Here is an inductive step. Assume for definiteness that $j + 1$ is odd (the case, when $j + 1$ is even, is similar). The distance between $x$ and $w_{j+1}(c)$ passes through a point $z' \in F(p)$ ($z' \in F(q)$ if $j + 1$ is even). Then

$$d(w_j(c), x) = d(w_j(c), z) + d(z, x) \leq d(w_j(c), z') + d(z', x),$$

$$d(w_{j+1}(c), x) = d(w_{j+1}(c), z') + d(z', x),$$

but $d(w_{j+1}(c), z') = d(w_j(c), z')$ (this is because $w_{j+1} = s^{m_j}w_j$ and $z'$ is fixed by $p$). Hence

$$d(w_j(c), x) \leq d(w_{j+1}(c), x),$$

but also

$$d(w_{j+1}(c), x) \leq d(w_{j+1}(c), z) + d(z, x) = d(w_j(c), z) + d(z, x) = d(w_j(c), x),$$

and so $d(w_{j+1}(c), x) = d(w_j(c), x)$. This proves the claim.

**Claim 3.** Let $x \in F(p) \Delta F(q)$ (here $\Delta$ is a symmetric difference of sets), $c \in A$. Suppose that the distance between $w_i(c)$ and $x$ doesn’t pass through a point in $F(p) \cap F(q)$. Then $d(w_i(c), x) \geq \lfloor i/2 \rfloor D(A)$.

**Proof of Claim 3.** Suppose first that $x \in F(p) \setminus F(q)$. We prove the statement by induction on $i$. The base of induction is trivial, so we show the inductive step: the statement is true for $i$ and we need to show it for $i + 1$. If $i$ is even then, since $\lfloor i/2 \rfloor = \lfloor (i + 1)/2 \rfloor$ and because $d(w_{i+1}(c), x) = d(w_i(c), x)$ (this is since $i$ is even and $x \in F(p)$) the statement follows immediately. So, assume $i$ is odd. Then the distance between $w_{i+1}(c)$ and $x$ passes through a point $z \in F(q)$. Now two things can happen. Suppose first for some $j \leq i$ the distance between $w_j(c)$ and $z$ passes through a point $z' \in F(p) \cap F(q)$. Then by Claim 2, the distance between $z$ and $w_{i+1}(c)$ must pass through $z'$. Now

$$d(w_{i+1}(c), x) = d(w_{i+1}(c), z) + d(z, x) = d(w_{i+1}(c), z') + d(z', x)\geq d(w_{i+1}(c), z') + d(z', x).$$
And so the distance between \( w_i+1(c) \) and \( x \) passes through a point \( z' \in F(p) \cap F(q) \). Contradiction with the assumptions of the claim. So, for no \( j \leq i \) the distance between \( w_j(c) \) and \( x \) passes through a point in \( F(p) \cap F(q) \). Then, applying induction to \( w_i(c) \) and \( z \), we get \( d(w_i(c), z) \geq \lfloor i/2 \rfloor D(A) \). But since \( d(w_i+1(c), z) = d(w_i(c), z) \) and since \( d(x, z) \geq D(A) \) we get
\[
d(w_i+1(c), x) \geq \lfloor i/2 \rfloor D(A) + D(A) \geq \lfloor (i + 1)/2 \rfloor D(A).
\]
In the case, when \( x \in F(q) \setminus F(p) \), the distance increases by \( D(A) \) at even stages of the construction, the rest of the argument for this case is similar. The claim is proved.

Fix now \( c \in A \) and \( y \in F(q) \). It remains to show that
\[
d(w_{2N+2}(c), y) = \min\{d(w_{2N+2}(c), z) + d(z, y) : z \in F(p) \cap F(q)\}.
\]
We now have two cases (we'll show, though, that Case 2 is impossible).

**Case 1.** For some \( i \leq 2N + 2 \) the distance between \( w_i(c) \) and \( y \) passes through a point \( z \in F(p) \cap F(q) \). Then
\[
d(y, w_i(c)) = \min\{d(y, z) + d(z, w_i(c)) : z \in F(p) \cap F(q)\}.
\]
Applying Claim 2 for \( j = 2N + 2 \), we get
\[
d(y, w_{2N+2}(c)) = \min\{d(y, z) + d(z, w_{2N+2}(c)) : z \in F(p) \cap F(q)\}.
\]
And the theorem is proved for this case.

**Case 2.** For no \( i \leq 2N + 2 \) the distance between \( w_i(c) \) and \( y \) passes through a point in \( F(p) \cap F(q) \). Then by Claim 3
\[
d(w_{2N+2}(c), y) \geq (N + 1)D(A) > 2diam(A).
\]
Let, on the other hand, \( z \in F(p) \cap F(q) \) be any common fixed point. Then
\[
d(w_{2N+2}(c), y) \leq d(w_{2N+2}(c), z) + d(z, y) = d(c, z) + d(z, y) \leq 2diam(A).
\]
Contradiction. So this case never happens. \( \square \)

**Remark 4.13.** Note that the same result is also true for ordered metric spaces.

For this one just has to apply Proposition 4.11 at each step of the construction of \( \bar{p} \) and \( \bar{q} \).

Before we apply this result to the classes of topological similarity let us mention another application. For a subset \( A \subseteq U \) (\( A \subseteq \mathbb{Q}U \)) let \( Iso_A(U) \) (\( Iso_A(\mathbb{Q}U) \), respectively) denote the subgroup of isometries that pointwise fix \( A \). Recall a theorem of Julien Melleray from [5].

**Theorem 4.14** (Melleray). Let \( U \) be the Urysohn space, let \( A, B \subset U \) be two finite subsets. Then
\[
Iso_{A \cup B}(U) = \{Iso_A(U), Iso_B(U)\}.
\]
Let us give an equivalent reformulation of the above result.

**Theorem 4.15** (Melleray). Let \( U \) be the Urysohn space, let \( A, B \subset U \) be two finite subsets. Then for any \( \varepsilon > 0 \), for any \( p \in Iso_{A \cup B}(U) \), for any \( C \subseteq U \) there is \( q \in (Iso_A(U), Iso_B(U)) \) such that
\[
\forall x \in C \ d(p(x), q(x)) < \varepsilon.
\]
We show that one can actually eliminate the epsilon in the above reformulation.
Theorem 4.16. Let $U$ be the Urysohn space, let $A, B \subset U$ be two finite subsets. Then for any $p \in \text{Iso}_{A \cap B}(U)$ for any $C \subseteq U$ there is $q \in \langle \text{Iso}_A(U), \text{Iso}_B(U) \rangle$ such that
\[
\forall x \in C \ p(x) = q(x).
\]

Proof. Without loss of generality we may assume that $A \subseteq C$ and $B \subseteq C$. Let $D = C \cup p(C)$ then $p|_C$ is a partial isometry of $D$. Define two partial isometries $p_1$ and $p_2$ of $D$ by
\[
\forall x \in A \ p_1(x) = x,
\]
\[
\forall x \in B \ p_2(x) = x.
\]
Apply now Theorem 4.12 to $p_1$, $p_2$ and $D$ to get a metric space $D'$ and extension $q_1$ of $p_1$ and $q_2$ of $p_2$, and a word $w \in F_2$. Extend now $q_1$ by
\[
\forall x \in C \ q_1(w(q_1, q_2)(x)) = w(q_1, q_2)(p(x)).
\]
Such a $q_1$ is then a partial isometry of $D'$. Now extend $q_1$ and $q_2$ to full isometries (we still denote them by the same symbols) and set
\[
q = w^{-1}(q_1, q_2)q_1w(q_1, q_2).
\]
Then for any $x \in C$, $p(x) = q(x)$, and $q_1 \in \text{Iso}_A(U)$, $q_2 \in \text{Iso}_B(U)$. \qed

Note that if we start from metric spaces with rational distances, then the space $D'$, constructed in the proof, would also have rational distances. And we arrive at the

Corollary 4.17. Let $QU$ be the rational Urysohn space, let $A, B \subset QU$ be two finite subsets. Then
\[
\text{Iso}_{A \cap B}(QU) = \overline{\langle \text{Iso}_A(QU), \text{Iso}_B(QU) \rangle}.
\]

5. ISOMETRIES OF THE RANDOMLY ORDERED URYSOHN SPACE

There is a rich variety of linearly ordered Fraïssé limits, of which countable dense linear ordering without endpoints is the simplest example. In fact, as proved in [4], if the group of automorphisms of a particular Fraïssé class $K$ is extremely amenable, then there is a linear ordering on the Fraïssé limit of $K$ that is preserved by all automorphisms.

We consider another example of a linearly ordered Fraïssé limit: randomly ordered rational Urysohn space $QU_\prec$.

Let us briefly remind the definition of this structure. Formally speaking, one has to consider the Fraïssé class $M$ of finite ordered metric spaces with rational distances. Then $QU_\prec$ is, by definition, the Fraïssé limit of $M$. Intuitively one can think of this structure as a classical rational Urysohn space with a linear ordering on top (such that ordering is isomorphic to the ordering of the rationals) and such that this ordering is independent of the metric structure.

Our goal is to prove that every two-dimensional class of topological similarity in the group of automorphisms of $QU_\prec$ is meager. We would like to emphasize that the structure of conjugacy classes in $\text{Aut}(Q)$ and $\text{Aut}(QU_\prec)$ is substantially different. As was mentioned earlier there is a generic conjugacy class in $\text{Aut}(Q)$, while it is not hard to derive from results in [5], that each conjugacy class in $\text{Aut}(QU_\prec)$ is meager.

Recall (see [5], Definition 3.3)
Definition 5.1. Class $\mathcal{K}$ of finite structures satisfies \textit{weak amalgamation property} (WAP for short) if for every $A \in \mathcal{K}$ there is $B \in \mathcal{K}$ and an embedding $e : A \to B$ such that for all $C, D \in \mathcal{K}$ and all embeddings $i : B \to C$, $j : B \to D$ there are $E \in \mathcal{K}$ and embeddings $k : C \to E$, $l : D \to E$ such that $k \circ i \circ e = l \circ j \circ e$, i.e., in the following diagram paths from $A$ to $E$ commute (but not necessarily paths from $B$ to $E$).

\[
\begin{array}{c}
A \xrightarrow{e} B \\
| | & | \\
\downarrow i & \downarrow j \\
C & D \\
\downarrow k & \downarrow l \\
E
\end{array}
\]

Class $\mathcal{K}$ satisfies \textit{local weak amalgamation property} if for some $A \in \mathcal{K}$ weak amalgamation holds for the class of structures $B \in \mathcal{K}$ that extend $A$.

Definition 5.2. Let $\mathcal{K}$ be a Fraïssé class. We associate with it a class of structures $\mathcal{K}_p$. Elements of $\mathcal{K}_p$ are partial isomorphisms of $\mathcal{K}$, more precisely tuples $(A; p : A' \to A'')$, where $A$, $A'$ and $A'' \in \mathcal{K}$, $A', A'' \subseteq A$ and $p$ is an isomorphism.

Theorem 5.3 (Kechris–Rosendal, see [5], Theorem 3.7). \textit{Group of automorphisms of a Fraïssé class $\mathcal{K}$ has a non-meager conjugacy class if and only if class $\mathcal{K}_p$ satisfies local weak amalgamation property.}

Proposition 5.4. Every conjugacy class in $\text{Aut}(\mathbb{QU}_\prec)$ is meager.

Proof. By Theorem 5.3 it is enough to show that the class $\mathcal{M}_p$ has no local WAP. Let $A = (A, \phi : A' \to A'') \in \mathcal{M}_p$, and assume without loss of generality that $\phi$ has at least one non-fixed point (otherwise take an extension of $\phi$). We claim that the class of structures that extend $A$ does not have WAP.

Fix $B = (B, \psi : B' \to B'')$ that extends $A$ and assume for notational simplicity that $A \subseteq B$. Let $x \in A'$ be such that $\phi(x) \neq x$ and let $\text{Orb}_\phi(x)$ be the orbit of $x$ under $\phi$. Then $\text{Orb}_\phi(x) \supseteq \text{Orb}_\phi(x)$. Now take (by Lemma 4.9 and Proposition 4.5) two structures $C = (C, \sigma : C' \to C'') \in \mathcal{M}_p$, $D = (D, \tau : D' \to D'') \in \mathcal{M}_p$ with embeddings $i : B \to C$, $j : B \to D$ and such that $\text{Orb}_{\sigma \circ i}(x)$ and $\text{Orb}_{\tau \circ j}(x)$ are disjoint over $\text{Orb}_\phi(x)$. Then there is no weak amalgamation of $C$ and $D$ over $B$ and $A$. \hfill \Box

With classes of topological similarity the situation is rather different. All non-trivial elements in $\text{Aut}(\mathbb{QU}_\prec)$ fall into a single class of topological similarity. And more generally, if $\mathbb{K}$ is any countable linearly ordered structure and $\text{Aut}(\mathbb{K})$ is endowed with a topology of pointwise convergence ($\mathbb{K}$ is discrete here), then $\text{Aut}(\mathbb{K})$ has exactly two classes of topological similarity (unless $\text{Aut}(\mathbb{K}) = \{\text{id}\}$, then, of course, there is only one): all non-trivial automorphisms generate a discrete copy of $\mathbb{Z}$ and hence fall into a single class. Thus, in spite of the previous proposition, it makes sense to ask if there is a non-meager two-dimensional similarity class in $\text{Aut}(\mathbb{QU}_\prec)$.
We define the notions of elementary and piecewise elementary pairs of partial isomorphisms of $\text{QU}_<$ and the notion of liberation exactly like for the partial isomorphisms of the rationals.

It turns out that the analog of Theorem 3.15 for the randomly ordered Urysohn space takes place. Let us first briefly sketch the idea of the proof before diving into the details. We will prove that, again, for a generic pair there is a sequence of reduced words, such that this pair converges along it. One can repeat all the arguments up to Lemma 3.14 (only obvious changes are necessary). So one gets a triple $(p', q', w)$ that liberates $p$ in $(p, q)$. But now, opposite to the case of rationals, one can not in general declare that $p'(w(p', q')(c)) = c$ for $c \in \text{Ess}(p) \cup \text{Ess}(q)$, since such a $p'$ may be not an isometry. At this moment we have to take further extensions of $p'$ and $q'$. But once an analog of Lemma 3.14 is proved for the Urysohn case, the rest of Theorem 3.15 goes unchanged.

If $p$ is a partial isometry, we can use amalgamation of its domain with a one point metric space over an empty set to add a fixed point for $p$. Using this observation the following two lemmata, which are analogs of Lemma 3.12 and Lemma 3.11, are proved like for the rationals, and we omit the details.

**Lemma 5.5.** Let $(p, q)$ be a piecewise elementary pair of partial isomorphisms of $\text{QU}_<$ and assume a triple $(p', q', w)$ liberates $p$ in $(p, q)$. Let $u = t^n v$ be a reduced word such that $u v$ is irreducible. Then there is a triple $(p'', q'', u v)$ that liberates $p$ in $(p, q)$. Moreover, one can take $p''$ to be an extension of $p'$ and $q''$ to be an extension of $q'$.

**Lemma 5.6.** Let $(p, q)$ be a piecewise elementary pair of partial isomorphisms of $\text{QU}_<$ and $u \in F(s, t)$ be a reduced word. Then there is a triple $(p', q', u v)$ such that $\text{Ess}(p') \cup \text{Ess}(q')$ and such that $|u v| = |u| + |v|$.

**Lemma 5.7.** For any pair $(p, q)$ of partial isomorphisms of the $\text{QU}_<$ and any word $u \in F(s, t)$ there are extensions $p'$ and $q'$ of $p$ and $q$ respectively and a reduced word $w = u v$ such that $w(p', q')(c) = c$ for any $c \in \text{dom}(p) \cup \text{dom}(q)$.

**Proof.** We can assume that $(p, q)$ is piecewise elementary. By Lemma 5.6 there are extensions $\bar{p}$, $\bar{q}$ of $p$ and $q$ and a reduced word $u v$ such that $(\bar{p}, \bar{q}, u v)$ liberates $p$ in $(p, q)$. Now apply Theorem 4.12 (with Remark 4.13 and Lemma 3.11) to $\bar{p}$, $\bar{q}$ and $w = u v$.

To get extension $\bar{p}$ and $\bar{q}$ and a reduced word $v'$. Note that $v' u v$ is reduced, because $v$ starts from a power of $t$ and $v'$ by construction ends in a power of $s$. By the item 6 of Theorem 4.12 we can extend $\bar{p}$ to $p'$ by declaring

$$p'\big|_{v' u v(\text{dom}(p) \cup \text{dom}(q))} = 1.$$  

Set $q' = \bar{q}$ and $w = (v' u v)^{-1} s(v' u v)$. It is easy to see that $w(p', q')(c) = c$ holds for any $c \in \text{dom}(p) \cup \text{dom}(q)$.

**Theorem 5.8.** Every two-dimensional class of topological similarity in $\text{Aut}(\text{QU}_<)$ is meager.

**Proof.** Repeat the proofs of Lemma 3.14 and Theorem 3.15 using Lemma 5.7 instead of Lemma 3.13.
Remark 5.9. All the results in this section can be proved for the randomly ordered random graph in the same way, as they were proved for the randomly ordered rational Urysohn space. One can also formally deduce this case from the above results viewing graphs as metric spaces with all the distances in \{0, 1, 2\}.
