In this work we study the effects of a longitudinal periodic potential on a parabolic quantum wire defined in a two-dimensional electron gas with Rashba spin-orbit interaction. For an infinite wire superlattice we find, by direct diagonalization, that the energy gaps are shifted away from the usual Bragg planes due to the Rashba spin-orbit interaction. Interestingly, our results show that the location of the band gaps in energy can be controlled via the strength of the Rashba spin-orbit interaction. We have also calculated the charge conductance through a periodic potential of a finite length via the non-equilibrium Green’s function method combined with the Landauer formalism. We find dips in the conductance that correspond well to the energy gaps of the infinite wire superlattice. From the infinite wire energy dispersion, we derive an equation relating the location of the conductance dips as a function of the (gate controllable) Fermi energy to the Rashba spin-orbit coupling strength. We propose that the strength of the Rashba spin-orbit interaction can be extracted via a charge conductance measurement.

I. INTRODUCTION

During the last two decades there has been much interest in using the electron spin in electronic devices. This research field, often referred to as spintronics, has already made great impact on metal-based information storage systems. There are hopes that a similar success can also be achieved in semiconductor based systems. Manipulating the spins of the electrons via external magnetic fields over nanometer length scales is not considered feasible. Another, more attractive, method is to use electric fields to manipulate electron spins via spin-orbit interaction. The spin-orbit interaction arises from the fact that an electron moving in an external electrical field experiences an effective magnetic field in its own reference frame, that in turn couples to its spin via the Zeeman effect.

In condensed matter systems, the spin-orbit interaction is found in crystals with asymmetry in the underlying structure. In bulk this is seen in crystals without an inversion center (e.g. zincblende structures) and is termed the Dresselhaus spin-orbit interaction. On the other hand the structural asymmetry of the confining potential in heterostructures gives rise to the so called Rashba term. The Rashba interaction has practical advantages in that it depends on the electronic environment of the heterostructure which can be modified in sample fabrication and in-situ by gate voltages. This results in the possibility of varying the spin-orbit interaction on the nanometer scale. Interestingly, even structurally symmetric heterostructures can present spin-orbit interaction provided that coupling between subbands of distinct parities is allowed.

The spin-orbit strength can be measured in a variety of different experimental setups. In a magnetoresistance measurement via Shubnikov-de Haas oscillations, weak (anti-) localization, or electron spin resonances in semiconducting nanostructures, or quantum dots, or optically via spin relaxation, spin precession, spin-flip Raman scattering, or radiation-induced magnetoresistance oscillations.

In this paper we propose a method for extracting the strength of the Rashba spin-orbit interaction via a charge conductance measurement. This method does not require the use of external magnetic fields or radiation sources. We consider a quantum wire modulated by an external periodic potential, Fig. 1. Essentially, the method relies on the fact that the Rashba-induced shifts of the band gap positions in energy dramatically alter the charge conductance of the superlattice.

In a magnetoresistance measurement via Shubnikov-de Haas oscillations, weak (anti-) localization, or electron spin resonances in semiconducting nanostructures, or quantum dots, or optically via spin relaxation, spin precession, spin-flip Raman scattering, or radiation-induced magnetoresistance oscillations.

FIG. 1. Schematic of the proposed experimental setup. The top gates produce the parabolic confinement of the quantum wire while the finger gates produce the longitudinal periodic potential. The Rashba spin-orbit interaction is controlled by the backgate.
structure of an infinite parabolically confined quantum wire. The energy bands clearly show band gaps that are renormalized by the Rashba interaction. Interestingly, the band gaps shift in energy as the strength of the Rashba interaction is varied. The location of the band gaps are at the crossing of energy bands from adjacent Brillouin zones. These energy bands can be calculated via an analytical approximation scheme.

Using Non-Equilibrium Green’s Functions (NEGF) and the Landauer formalism we calculate the charge conductance through a finite region containing both a periodic potential and the Rashba interaction. In the conductance we find several dips appearing at different location in energy. Moreover, these conductance dips coincide with renormalized band gaps of the superlattice. As with the band gaps the positions of the conductance dips are at the crossing points of the energy bands from next neighbor Brillouin zones. For a wide range of Rashba spin-orbit interaction strengths some of the conductance gaps depend on the Rashba spin-orbit interaction. Via the NEGF method and the Landauer formalism we introduce in Sec. III a numerical scheme to calculate the conductance dips via Eq. (12). Figure 1 shows a schematic of the proposed experimental setup.

This paper is organized as follows. In Sec. II we calculate the energy bands of the infinite wire superlattice via direct diagonalization. By using an analytical approximation scheme we then show how the resulting band gaps depend on the Rashba spin-orbit interaction. Via the NEGF method and the Landauer formalism we introduce in Sec. III a numerical scheme to calculate the charge conductance through a finite region. This region is connected to electron reservoirs to the left and right, and contains both a periodic potential and a Rashba spin-orbit coupling. In Sec. IV we then show that the band picture of the infinite wire superlattice, developed in Sec. II, is applicable to the finite length periodic potential. We close Sec. IV with a discussion about possible experimental procedures. Lastly, in Sec. V we show that our results are robust against fluctuations in the strength and width of the periodic potential.

II. MODEL SYSTEM: THE INFINITE WIRE SUPERLATTICE

We investigate an infinite quasi-1D parabolic wire with a uniform Rashba spin-orbit coupling in the presence of a longitudinal modulation described by the potential

$$V_p(x) = V_{p0} \sum_n c_n e^{in2\pi x},$$

where $\lambda$ is the period of the superlattice. The Hamiltonian that describes this system is

$$H = \frac{1}{2m^*}(\hat{p}_x^2 + \hat{p}_y^2) + \frac{1}{2}m^*\omega_0^2 y^2 + \frac{\alpha}{\hbar}(p_y \sigma_x - p_x \sigma_y) + V_p(x), \quad (2)$$

were $m^*$ is the effective mass, $p_x$ and $p_y$ are the momentum operators in the longitudinal and transverse direction of the wire, $\alpha$ is the Rashba spin-orbit strength, and $\omega_0$ is the confinement frequency of the parabolic potential.

To find the eigenvalues of the Hamiltonian in Eq. (2) it is convenient to introduce the standard ladder operator $\hat{a}$ of the parabolic confinement and rotate the spin operators so that the $p_x$ part in the Rashba interaction term couples to the $\sigma_z$ operator:

$$\tilde{H} = e^{-i\alpha \sigma_z/4} H e^{i\alpha \sigma_z/4} = \frac{1}{2} \left(k - \frac{2\pi}{\lambda} n\right)^2 \hat{a}^\dagger \hat{a} - q_R \left(k - \frac{2\pi}{\lambda} n\right) \hat{\sigma}_z + \frac{iq_R}{\sqrt{8}} \left(\hat{\sigma}_+ (\hat{a}^\dagger - \hat{a}) - \text{h.c.}\right) + V_p(x) = \tilde{H}_0 + \tilde{H}_1, \quad (3)$$

here $\hat{\sigma}_+ = \hat{\sigma}_x + i\hat{\sigma}_y$ is the spin ladder operator, $q_R = \frac{m^* \alpha}{\hbar}$ is the rescaled Rashba strength and $h \left(k - \frac{2\pi}{\lambda} n\right)$ are the eigenvalues of the operator $p_x$. In Eq. (3) we scale all lengths in oscillator length $l = \sqrt{\hbar/m^*\omega_0}$ and all energies in $\hbar\omega_0$. We separate the Hamiltonian $\tilde{H}$ into a diagonal part,

$$\tilde{H}_0 = \frac{1}{2} \left(k - \frac{2\pi}{\lambda} n\right)^2 \hat{a}^\dagger \hat{a} - q_R \left(k - \frac{2\pi}{\lambda} n\right) \hat{\sigma}_z + c_0 V_{p0}, \quad (4)$$

and a non-diagonal part

$$\tilde{H}_1 = \frac{iq_R}{\sqrt{8}} \left(\hat{\sigma}_+ (\hat{a}^\dagger - \hat{a}) - \text{h.c.}\right) + \sum_{n \neq 0} c_n e^{in\pi/2}. \quad (5)$$

A. Zeroth-order eigenstates and eigenvalues

The eigenstates of the $\tilde{H}_0$ Hamiltonian are represented by the kets $|k, m, s\rangle$. Here $m$ is the quantum number of the harmonic transverse energy bands, i.e. the eigenvalue of the $\hat{a}^\dagger \hat{a}$ operator, and $s$ is the eigenvalue of the $\hat{\sigma}_z$ operator with $s = +1$ and $s = -1$ denoting the spin up and spin down states, respectively. The corresponding eigenenergies are

$$E_{m, s}(k) = \frac{1}{2} \left(k - \frac{2\pi}{\lambda} n\right)^2 + \frac{1}{2} + m - sq_R \left(k - \frac{2\pi}{\lambda} n\right) + c_0 V_{p0}. \quad (6)$$
FIG. 2. (a) Energy bands of the zeroth-order Hamiltonian \( \tilde{H}_0 \) for \( l = 50 \text{ nm}, \lambda = 62 \text{ nm} = 1.2l, \alpha = 8 \text{ meVnm} \) \( (q_R = 0.21l^{-1}), k^*_c = 2.3l^{-1}, c_0 = 1/2, \) and \( V_{\rho 0} = 0.5 \). (b) Crossing of the energy bands corresponding to the \( |k, 0, -1 \rangle, |k, 1, +1 \rangle, \) and \( |k - 2\pi/\lambda, 0, -1 \rangle \) states. (c) Crossing of the energy bands corresponding to the \( |k, 1, -1 \rangle, |k, 2, +1 \rangle, \) \( |k - 2\pi/\lambda, 1, -1 \rangle, \) and \( |k - 2\pi/\lambda, 0, +1 \rangle \) states. (d) Same as (c) but for higher bands, i.e. \( m \to m + 1 \).

A plot of the \( E_m(k) \) energy bands vs \( k \) in half of the Brillouin zone, i.e., \( k = 0 \ldots \pi/\lambda \), can be seen in Fig. 2 (a).

The Hamiltonian \( \tilde{H}_1 \) introduces couplings \( i \) between the \( |k, m, s \rangle \) and the \( |k, m \pm 1, \bar{s} \rangle \) states, due to the Rashba interaction, and \( ii \) between the \( |k, m, s \rangle \) and the \( |k \pm n2\pi/\lambda, m, s \rangle \) states, due to the periodic potential. Note that the coupling is strongest where the energy bands corresponding to these states cross each other. For some particular Rashba strength \( \alpha^* \) the energy bands associated with the states \( |k, 0, -1 \rangle \) and \( |k, 1, +1 \rangle \) of \( \tilde{H}_0 \) cross at \( k^*_c = 1/(2q_R^*), \) where \( q_R^* = \alpha^*m^*/\hbar^2. \) If we choose the period \( \lambda \) of the superlattice potential, Eq. 11, as

\[
\lambda = 2\pi \frac{q_R^*}{1 + 2(q_R^*)^2},
\]

the \( |k - 2\pi/\lambda, 0, -1 \rangle \) energy band will also cross at \( k^*_c. \) This crossing point occurs in energy at

\[
E^* = \frac{1}{8q_R^*} + 1 + c_0 V_{\rho 0},
\]

see Fig. 2 (b). In the following we refer to this particular choice of parameter \( \alpha^* \) as the reference spin-orbit coupling strength. Similar crossing also occur at \( k^*_c \) with the energy bands associated with the states \( |k, m, -1 \rangle, |k, m + 1, +1 \rangle, \) and \( |k - 2\pi/\lambda, m, -1 \rangle \) for energies \( E^* + m\hbar\omega_0 \) with the energy band corresponding to the state \( |k - 2\pi/\lambda, m - 1, +1 \rangle \) crossing close by. The crossings for \( m = 1 \) and \( m = 2 \) can be seen, respectively, in Fig. 2 (c) and (d).

B. Coupling between eigenstates

We calculate the eigenenergies of the full Hamiltonian, \( \tilde{H} \), via direct diagonalization. The resulting energy bands are plotted in Fig. 3 (a). The energy bands that cross at \( k^*_c \) and the one crossing close by, see Sec. IA, correspond to the states coupled by \( \tilde{H}_1 \). A blow up of the resulting energy gaps can be seen in Fig. 3 (b). At \( E^* \) the coupling results in a double energy gap, see Fig. 3 (c), and a triple energy gap at the higher energy crossings, see Fig. 3 (d) and (e). In Fig. 3 the spin-orbit strength is at the reference value \( \alpha^* \).

Note that for a non-zero Rashba coupling, as in Fig. 3 the energy gaps have shifted from the Bragg plane at \( k = \pi/\lambda \). This is because the spin-orbit interaction shifts the wave-number \( k \) of the electrons in the longitudinal direction and thus renormalizes the locations of interferences.

\[
k \text{[l}^{-1}\text{]}\]

FIG. 3. (a) Energy bands of the Hamiltonian \( \tilde{H} = \tilde{H}_0 + \tilde{H}_1 \) for the same parameters as used in Fig. 2. The energy bands are calculated via direct diagonalization of \( \tilde{H} \). (b) A blow up focusing on the band gaps of the first three crossings at \( k^*_c. \) (c) The band gaps formed at the energy band crossing shown in Fig. 2 (b). In (d) and (e), the energy band crossings shown in Fig. 2 (c) and (d), respectively.

When the strength of the Rashba interaction is changed the crossing points \( k^*_c \) of the energy bands shift and with them the energy gaps. These crossing points
can be worked out analytically by using the eigenener-
gies of the effective Rashba Hamiltonian of the parabolic wire, which are
\[ \varepsilon_{m,\uparrow}(k, qR) = \frac{(k - n \frac{2\pi}{\lambda})^2}{2} + m - \frac{q_{R}}{2(1 + 2q_{R}(k - n \frac{2\pi}{\lambda}))} \]
\[ + \Delta_m \left(k - n \frac{2\pi}{\lambda}, qR\right) + c_0 V_{p0}, \quad (9) \]
and
\[ \varepsilon_{m,\downarrow}(k, qR) = \frac{(k - n \frac{2\pi}{\lambda})^2}{2} + m + 1 - \frac{q_{R}}{2(1 + 2q_{R}(k - n \frac{2\pi}{\lambda}))} \]
\[ - \Delta_{m+1} \left(k - n \frac{2\pi}{\lambda}, qR\right) + c_0 V_{p0}, \quad (10) \]
for \( k > \frac{2\pi}{\lambda} \geq 0 \). For \( k > \frac{2\pi}{\lambda} < 0 \) \( \varepsilon_{m,\uparrow}(k, qR) = \varepsilon_{m,\downarrow}(-|k|, qR) \). In Eq. (9) and (10), the energy bands described by Eq. (10) can be seen in Fig. 4. For higher energies there are further crossing points, calculated from Eq. (9) and (10), can be seen in Fig. 4. It is possible to extract the value of \( \alpha \). The linear parts of the trajectories are best suited for fitting. It would therefore be convenient that the range of \( \alpha \) extracted via the fitting is contained within the linear region. This can be achieved by choosing a sufficiently low \( \alpha \)-value (and thus \( \lambda \), Eq. (7)).

We present below a linearized equation for the crossing point between the energy bands. The black dashed lines are the linearization of the left moving trajectories around \( \alpha_0 \). We also mark the values \( \alpha^* = 8 \text{ meVnm} \) and \( \alpha_1 = 12 \text{ meVnm} \) onto the y-axis. These values are used for the conductance results in Fig. 1.

C. Extracting the Rashba coupling

We will show in Sec. 11 that the band gaps appear as dips in the charge conductance through a finite periodic potential. By fitting the measured energy shift of the conductance dips to the trajectories in Fig. 1 it is possible to extract the value of \( \alpha \). The linear parts of the trajectories are best suited for fitting. It would therefore be convenient that the range of \( \alpha \) extracted via the fitting is contained within the linear region. This can be achieved by choosing a sufficiently low \( \alpha \)-value (and thus \( \lambda \), Eq. (7)).

We present below a linearized equation for the \( \alpha \)-value of the crossing point between the energy bands corresponding to the states \( |k, m + 1, +1\rangle \) and \( |k - \frac{2\pi}{\lambda}, m, -1\rangle \) as a function of Fermi energy. By Taylor expanding around some point \( \alpha_0 \) in the linear region of the trajectories and making a linear approximation we obtain

\[ \alpha = \frac{\hbar^2}{m^*} \frac{\hbar}{\lambda} \left[ q_{R0} - \frac{E_F - \frac{1}{2} V_{p0} - F(m)}{G(m)} \right], \quad (12) \]

here \( F(m) \) and \( G(m) \) are known functions of the energy band index \( m \), see Eq. (15) and Eq. (17). The derivation of Eq. (12) is shown in the appendix. In Fig. 4 we plot as dashed lines linearized trajectories described by Eq. (12) where we have chosen \( \alpha_0 = 20 \text{ meVnm} \).
III. FINITE PERIODIC POTENTIAL

In this section we calculate in the linear response the conductance through a finite periodic potential. This is done via the Landauer formula together with the NEGF method.

A. The system setup

We consider a hardwalled wire of width $L_y$ with a transverse parabolic potential. We divide the wire into a finite central region of length $L_z$ and semi-infinite left and right parts, see Fig. 5. The central region includes a Rashba spin-orbit interaction described by a symmetrized Hamiltonian which is turned on smoothly, at both the left and right ends. In the central region we also assume a longitudinal periodic potential that represents the potential due to the fingergates. We describe the central region by the Hamiltonian

$$
H_C = \frac{1}{2m^*}(p_x^2 + p_y^2) + \frac{1}{2}m^*\omega_0^2y^2 + \frac{1}{2}\hbar\{\alpha(x,y), p_y\hat{\sigma}_x - p_x\hat{\sigma}_y\}
+ V_{p0} \frac{1}{2} \left(1 - \cos \left(\frac{2\pi}{\lambda}x\right)\right)
$$

(13)

Here $\{,\}$ denotes an anticommutator.

The left and right leads contain the same parabolic potential as in the center region but neither a Rashba spin-orbit interaction nor a periodic potential in the longitudinal direction, i.e., they are described by the Hamiltonian

$$
H_{L/R} = \frac{1}{2m^*}(p_x^2 + p_y^2) + \frac{1}{2}m^*\omega_0^2y^2.
$$

(14)

The total system, $H_T = H_L + H_C + H_R$, is discretized via the finite difference method on a grid of $N_x \times N_y$ points with a mesh size $a$. A schematic of the system can be seen in Fig. 5.

B. The numerical formalism

Here we use the NEGF method to calculate the charge conductance. The method requires us to find the retarded Green’s function of the central region $G^R_C$. To do this we have to isolate $G^R_C$ from the infinite matrix equation describing the retarded Green’s function of the total system

$$(E I - H_T)G^R_T = I.
$$

(15)

By separating the total Green’s function into a left, right, and central part we can write Eq. (15) as

$$
\begin{bmatrix}
E I - H_L & -H_{Cj} & 0 \\
-H_{CL} & E I - H_C & -H_{CR} \\
0 & -H_{RC} & E I - H_R
\end{bmatrix}
\begin{bmatrix}
G^R_L & G^R_{CL} & G^R_{LR} \\
G^R_{CR} & G^R_C & G^R_{CR} \\
G^R_{RL} & G^R_{RC} & G^R_R
\end{bmatrix}
= \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}.
$$

(16)

The matrices $H_{Cj} = H_{jC} = a I$, couple together the central region to the left ($j = L$) and right leads ($j = R$). Here $t = \hbar/2m^*a^2$ is the tight-binding hopping parameter that results from the discretization. Multiplying out Eq. (16) gives nine matrix equations from which we can isolate a finite matrix equation for $G^R_C$. This is done by treating the contributions from the infinite leads as self-energies $\Sigma_L, \Sigma_R$. The matrix equation for $G^R_C$ is

$$(E-I-H_C-\sum_j \Sigma_j)G^R_C = I,
$$

(17)

and the self-energy of lead $j = L$, $R$ is $\Sigma_j = H_{Cj}G^\dagger_jH_{jC}$ where $G^\dagger_j$ is the Green’s function of lead $j$ and is determined analytically. Here $H_C$ is the discretized Hamiltonian of Eq. (2) over the central region. All the matrices are $2N_xN_y \times 2N_xN_y$ matrices. In order to save computational power only the necessary Green’s function matrix elements are calculated with the recursive Green’s function method. Here we are interested in low biases and hence focus on the linear response regime. From the Green’s function the charge conductance at the Fermi Energy $E_F$ can be calculated, via the Fisher-Lee relation

$$
G(E_F) = \frac{2e^2}{\hbar} Tr \left[ \Gamma_R G^R_C \Gamma_L G^a_C \right],
$$

(18)

where $\Gamma_j = -2\text{Im} (\Sigma_j)$ and $G^a = (G^R)^\dagger$. In what follows we use Eq. (13) to calculate the charge conductance through our system.
C. Numerical values used in the calculation

In our simulations we consider a Ga$_{1-x}$In$_x$As alloy with an effective mass $m^*=0.041m_e$, with $m_e$ being the bare electron mass. The width of the wire is set as $L_y=500$ nm and its length as $L_x=4.92$ $\mu$m. The oscillator length is $l=50$ nm which corresponds to $\hbar\omega_0=0.74$ meV. For the discretization we use $N_x\times N_y=600\times63$ points with $a=8.1$ nm being the distance between nearest points. This corresponds to a tight-binding hopping parameter $t=29$ meV=39 $\hbar\omega_0$. We choose the reference Rashba strength as $\alpha^*=8$ meV nm (i.e. $k^*_R=0.21$ $l^{-1}$) which results in an energy band crossing point at $k^*_c=1/(2q^*_R)=2.3$ $l^{-1}$ and a period $\lambda=\pi/(k^*_c+q^*_R)=1.23$ $l=7.62$ $a=61.5$ nm. This corresponds to $L_x/\lambda=80$ fingergates. The strength of the periodic potential is set as $V_{p0}=0.5\hbar\omega_0=0.37$ meV.

IV. RESULTS

In Fig. 6 (a) we compare the calculated conductance, Fig. 6 (b) and (c), as a function of Fermi energy. Results for two values of $\alpha$ are presented, $\alpha^*=8$ meV nm and $\alpha_1=12$ meV nm. For comparison we also plot in Fig. 6 (a) the conductance through a non-periodic potential $V_{p}(x)=1/2V_{p0}$ for the same values $\alpha$ mentioned above, i.e. the corresponding gapless systems. Each energy gap is associated to its corresponding conductance dip via a labeled arrow. The labeling on the arrows is the same labeling as those of the trajectories in Fig. 4. We see that there is a good correspondence between the dips in conductance and the gaps in the energy band for both $\alpha^*$ and $\alpha_1$. This indicates that the behavior of the finite periodic potential can be properly described with the band model from the infinite periodic potential. In Fig. 6 we can see how the band gaps shift in energy as a function of $\alpha$. We want see if the energy shift of conductance dips correlates with the shift of the band gaps. This is most easily seen by considering the differential conductance

$$\frac{\partial G}{\partial E_F} = \frac{G(E_{F+1}) - G(E_F)}{E_{F+1} - E_F}.$$  \hspace{1cm} (19)

In Fig. 6 we plot $\partial G/\partial E_F$ as a function of $E_F$ and $\alpha$. There we see the conductance steps of the parabolic wire as relatively straight vertical trajectories appearing at the tic marks on the horizontal axis. The rest of the trajectories in Fig. 6 correspond to dips in the charge conductance. By comparing the trajectories, that the dips in charge conductance form, to the ones of the band gaps in Fig. 6 we see an excellent match. This firmly confirms that the conductance dips of the finite wire can be described via the band model for the superlattice. We also plot in Fig. 6 as light-gray lines the linearized trajectories of crossing points between the energy bands corresponding to the

![FIG. 6. (Color online) Comparison between energy gaps of the infinite superlattice and conductance dips of the finite periodic potential. In (a) the results from the numerical calculation of the conductance is shown for $\alpha_1=12$ meVnm, and $\alpha^*=8$ meV nm. Note that the conductance curve for $\alpha_1$ has been shifted by $2\times2\epsilon^2/h$ for clarity. The results for a wire with a non-periodic potential $V_p(x)=1/2V_{p0}$ is plotted with black solid lines. In (b) and (c) the energy bands of the infinite wire superlattice are plotted for the same $\alpha$ values as in (a), respectively. Note that (c) is the same figure as Fig. 3 (b), but rotated clockwise by $90^\circ$. The correspondence between the nine pairs of dips and band gaps are indicated by the labeled arrows.](image)

| $k, m+1, +1$ and $|k-2\pi/\lambda, m, -1$ states, see Eq. (12). The trajectories are linearized around $\alpha=20$ meV nm and are identical to the straight dashed lines in Fig. 4.]

A. Discussion of possible experimental procedures

From Fig. 7 we can extract the Rashba spin-orbit coupling by fitting the linear energy shift of the conductance dips, via Eq. (12). The energy shift, i.e. the change in Fermi energy, is controlled by the chemical potential of the leads. The backgate that controls the spin-orbit strength introduces an extra shift in the Fermi energy (due to the electrostatic coupling of the backgate to the 2DEG). This shift can be compensated by changing the chemical potential of the leads by an equal amount. Similar methods have been used to probe the energy spectrum of quantum dots using transport methods. Another way to compensate for this shift is to use a combination of back and front gates. This has been experimentally demonstrated to control the Rashba spin-orbit interaction strength without introducing charging in the 2DEG.
FIG. 7. (Color online) Plot of the differential conductance $\partial G/\partial E$ between values of 0.2, 0.5, 1.0, and 1.5 as the strength of the periodic potential has been varied between values of 0.2, 0.5, 1.0, and 1.5 fingergates. Fig. 8 (b) shows results where trajectories of the crosspoints between the energy bands correspond to the Rashba spin-orbit coupling, $\alpha$. The linearized trajectories are linearized around $\alpha_0 = 20$ meVnm. The Rashba spin-orbit values, $\alpha^* = 8$ meVnm and $\alpha_1 = 12$ meVnm, corresponding to the curves in Fig. 8 are marked on the right border. Note that $\eta_R = m^*\alpha/h^2\ell$ and that the differential conductance $\partial G/\partial E_F$ is in arbitrary units.

V. VARIATIONS OF PARAMETERS IN THE PERIODIC POTENTIAL

The periodic potential plays a crucial role in the formation and behavior of the energy gaps. We therefore devote this section to study the effect that variations of parameters in the periodic potential has on the conductance. In what follows we consider variations on the length and strength of the periodic potential (Sec. V A) as well as random fluctuations on the period and strength of each finger gate potential (Sec. V B).

A. Changing the periodic potential parameters

Here we examine the effects of changing the strength of the periodic potential, $V_{p0}$, and the length $L_z$. In Fig. 8 (a) the length of the wire is varied such that it contains 10, 40, 80, or 160 fingergates with a fixed period $\lambda = 63$ nm. There we see the dips easily for $\geq 40$ fingergates and they become clearer for more fingergates. There is not much change between the conductance results for 80 and 160 fingergates, i.e. $\approx 80$ fingergates is an adequate number of fingergates. Fig. 8 (b) shows results where the strength of the periodic potential has been varied between values of 0.2, 0.5, 1.0, and 1.5 $\hbar\omega_0$. We see that the width of the conductance dips grows with larger $V_{p0}$. But as $V_{p0}$ increases the total conductance strength $G$ deteriorates due to interferences. This makes the detection of the conductance dips difficult.

B. Effects of fluctuations in the periodic potential

The periodic potential used in the previous section can be considered as being ideal. A more realistic case would be if there were some fluctuations in the potential. To verify the robustness of the results in the previous section we rerun the simulations with a non-ideal periodic potential. This is done by introducing a 5% Gaussian error in both the height and length of each potential hill created by the fingergates. Figure 9 (b) shows that extra noise is added to our conductance result; still the trajectories of the conductance dips are fairly visible. To counter against the noise introduced by fluctuations we could add extra periods to the periodic potential. This helps averaging out the noise, as can be seen in Fig. 9 (a) where we have quadrupled the length of the wire and the number of fingergates. This self-averaging is however slow and requires a large number of fingergates. Another solution, as we are mainly interested in the slope of the crosspoint trajectories, is actually to reduce the number of fingergates to an optimal number. As can be seen in Fig. 9 (c) we obtain many extra trajectories resulting from the imprecision of the period. But the slope of the trajectories of the conductance dips can be easily fitted for $\alpha \gtrsim 10$. As expected if we go down to as few as 10 fingergates the effects of the periodic potential is nearly washed out.
We have studied a parabolic quantum wire with Rashba spin-orbit interaction and a longitudinal periodic potential. We find that the energy gaps resulting from the periodic potential split up and shift from the Bragg plane due to the Rashba spin-orbit interaction. Above a certain spin-orbit strength some of the new energy gaps shift linearly in energy as a function of the Rashba spin-orbit strength. We propose that this effect can be used to measure the change in the Rashba spin-orbit strength, e.g. resulting from a voltage gate\footnote{The trajectories of the crossing points across the energy-Rashba spin-orbit coupling surface are then $\varepsilon_{m\downarrow}(k,\mathbf{q}_R)$ or $\varepsilon_{m\downarrow}(k,\mathbf{q}_R)$. The crossing points and their trajectories for the other energy bands, namely the ones corresponding to the states $(k, m+1, +1)$ and $(k-2\pi/\lambda, m-1)$, the $(k, m-1)$ and $(k-2\pi/\lambda, m-1)$, and the $(k, m+1, +1)$ and $(k-2\pi/\lambda, m-1)$, can be worked out in the same way.}. The energy gaps result in dips in the charge conductance. The energy shift of these dips can be fitted, by an analytical equation that we derive, Eq. \ref{eq:shift}, to extract the strength of the Rashba spin-orbit interaction. The advantage of the this method is that it only requires conductance measurement and not any external magnetic or radiation source.

Appendix A: Energy crossing points

In this appendix we calculate the crossing point $k_c$ of the $|k, m, -1\rangle$ and $|k-2\pi/\lambda, m-1, +1\rangle$ energy bands.

We need to solve the equation

\begin{equation}
\varepsilon_{m\downarrow}(k,\mathbf{q}_R) - \varepsilon_{m-1\downarrow}(k,\mathbf{q}_R) = \frac{2\pi}{\lambda}k - \frac{2\pi^2}{\lambda^2} + 1
\end{equation}

\begin{equation}
+ A(k,\mathbf{q}_R) - \Delta_{m+1}(k,\mathbf{q}_R) + \Delta_m(-k + 2\pi/\lambda, q_R) = 0
\end{equation}

for $k$. Here we used Eq. \ref{eq:eps} and \ref{eq:delta} and have defined

\begin{equation}
A(k,\mathbf{q}_R) = \frac{q_R^2}{2} \left( \frac{1}{1 - 2q_R k + \frac{4\pi\alpha}{\lambda q_R}} - \frac{1}{1 + 2q_R k} \right). \tag{A2}
\end{equation}

Equation \ref{eq:crossing} is a nonlinear equation which is hard to solve directly. An easier way is to linearize the $A(k)$ and $\Delta_m(k)$ functions around the point $k = k_c^\ast$. This approximation introduces little errors and allows us to write the crossing point as

\begin{equation}
k_c = \frac{2\pi^2}{\lambda^2} - 1 - B(m,\mathbf{q}_R) + C(m,\mathbf{q}_R)k_c^\ast \tag{A3}
\end{equation}

where

\begin{equation}
B(m,\mathbf{q}_R) = A(k_c^\ast,\mathbf{q}_R) - \Delta_{m+1}(k_c^\ast,\mathbf{q}_R) + \Delta_m(-k_c^\ast + 2\pi/\lambda, q_R), \tag{A4}
\end{equation}

and

\begin{equation}
C(m,\mathbf{q}_R) = \frac{\partial A(k,\mathbf{q}_R)}{\partial k} \bigg|_{k=k_c^\ast} - \frac{\partial \Delta_{m+1}(k,\mathbf{q}_R)}{\partial k} \bigg|_{k=k_c^\ast} \tag{A5}
\end{equation}

The $k$ value of the crossing point between the $\varepsilon_{m\downarrow}(k,\mathbf{q}_R)$ and $\varepsilon_{m-1\downarrow}(k,\mathbf{q}_R)$ bands remains almost constant as a function of $\alpha$. This is because these bands move at similar rate in opposite directions in $k$ space as $\alpha$ is changed. We take advantage of this when finding a linear equation around some point $\alpha_0$ in the straight segments of the trajectories. We know that $k_c^\ast$ is a crossing point for $\alpha = \alpha^\ast$ so we can, instead of using Eq. \ref{eq:crossing}, make the approximation that $k_c \approx k_c^\ast$ for all $\alpha$. We then linearize $\varepsilon_{m\downarrow}(k_c^\ast,\mathbf{q}_R)$ by Taylor expanding around $\alpha_0$. Solving for $\mathbf{q}_R$ in $\varepsilon_{m\downarrow}(k_c^\ast,\mathbf{q}_R)$ and scaling back to $\alpha$ we obtain

\begin{equation}
\alpha = \frac{q_R^2}{m^* l} \left[ q_{R0} - \frac{\varepsilon_{m\downarrow}^0 - F(m)}{G(m)} \right], \tag{A6}
\end{equation}
where
\[
F(m) = \frac{1}{2} (k^*_c)^2 + m + 1 - \frac{\eta^2_{R0}}{2(1 + 2q_{R0}k^*_c)} - \Delta_{m+1}(k^*_c, q_{R0})
\]
\[= 3.7 + m - \sqrt{6.0 \times 10^{-2}m^3 - 4.1 \times 10^{-2}m^2 + 0.20m + 0.79},
\]
\[
(A7)
\]
and
\[
G(m) = \frac{k^*_cq^2_{R0} + q_{R0}}{4(k^*_c)^2q^2_{R0} + 4k^*_cq_{R0} + 1} + \frac{\partial \Delta_{m+1}(k^*_c, q_{R0})}{\partial q_{R0}}
\]
\[\bigg|_{q_{R0} = R_0} = 9.8 \times 10^{-2}
\]
\[+ \frac{5.1 \times 10^{-4}m^4 - 2.7 \times 10^{-2}m^2 + 0.82m + 4.4}{\sqrt{2.4 \times 10^{-5}m^3 - 1.6 \times 10^{-4}m^2 + 0.79m + 3.1}}.
\]
\[
(A8)
\]
In the last steps of the Eq. (A7) and Eq. (A8) we have plugged in the values \(k^*_c = 2.35\) and \(q_{R0} = 0.537\), which correspond to \(\alpha^* = 8\) meVnm and \(\alpha_0 = 20\) meVnm. Note that all lengths are scaled in the oscillator length \(l = \sqrt{\hbar/m^*\omega_0}\) and all energies in \(\hbar\omega_0\).
