Some Geometric PDEs Related to Hydrodynamics and Electrodynamics

Yann Brenier*

Abstract

We discuss several geometric PDEs and their relationship with Hydrodynamics and classical Electrodynamics. We start from the Euler equations of ideal incompressible fluids that, geometrically speaking, describe geodesics on groups of measure preserving maps with respect to the $L^2$ metric. Then, we introduce a geometric approximation of the Euler equation, which involves the Monge-Ampère equation and the Monge-Kantorovich optimal transportation theory. This equation can be interpreted as a fully nonlinear correction of the Vlasov-Poisson system that describes the motion of electrons in a uniform neutralizing background through Coulomb interactions. Finally we briefly discuss an equation for generalized extremal surfaces in the 5 dimensional Minkowski space, related to the Born-Infeld equations, from which the Vlasov-Maxwell system of classical Electrodynamics can be formally derived.

2000 Mathematics Subject Classification: 58D05, 35Q, 82D10, 76B.
Keywords and Phrases: Hydrodynamics, Euler equations, Geodesics, System of particles, Monge-Ampère equations, Extremal surfaces, Electrodynamics, Born-Infeld equations.

1. The Euler equations of incompressible fluids

The motion of an incompressible fluid moving in a compact domain $D$ of the Euclidean space $\mathbb{R}^d$ can be mathematically defined as a trajectory $t \to g(t)$ on the set, subsequently denoted by $G(D)$, of all diffeomorphisms of $D$ with unit jacobian determinant. This space can be embedded in the set $S(D)$ of all Borel maps $h$ from $D$ into itself, not necessarily one-to-one, such that

$$\int_D \phi(h(x))dx = \int_D \phi(x)dx$$

for all $\phi \in C(D)$, where $dx$ denotes the Lebesgue measure, normalized so that the measure of $D$ is 1. For the composition rule, $G(D)$ is a group (the identity map $I$...
being the unity of the group), meanwhile $S(D)$ is a semi-group. Both $G(D)$ and $S(D)$ are naturally embedded in the Hilbert space $H = L^2(D, \mathbb{R}^d)$ of all square integrable mapping from $D$ into $\mathbb{R}^d$ and, therefore, inherit from $H$ a formal Riemannian structure. The equations of geodesics on $G(D)$ turn out to be exactly the equations of incompressible inviscid fluids introduced by Euler near 1750.

The Euler equations play a fundamental role in Fluid Mechanics (for geophysical flow modelling in particular) and their global well-posedness is one of the most challenging problems in the field of nonlinear PDEs. Their mathematical importance is confirmed by the recent publication of several books by Arnold-Khesin, Chemin, P.-L. Lions, Marchioro-Pulvirenti, as well as by Majda’s lecture in the Kyoto ICM.

From a geometric point of view (different from the usual PDE setting which consists in solving the Euler equations with prescribed initial conditions), it is natural to look for minimizing geodesics between the identity map and prescribed measure preserving maps. More precisely:

**Definition 1.1** Given $h \in G(D)$, find a curve $t \in [0, 1] \rightarrow g(t) \in G(D)$ satisfying $g(0) = I$, $g(1) = h$, that minimizes

$$A_D(g) = \frac{1}{2} \int_0^1 ||g'(t)||^2_{L^2} dt = \frac{1}{2} \int_0^1 \int_D |\partial_t g(t, x)|^2 dx dt.$$

The infimum is nothing but $\frac{1}{2}\delta_D^2(I, h)$, where $\delta_D$ denotes the geodesic distance on $G(D)$, and any smooth minimizer $g$ must be a smooth solution of the Euler equations (written in “Lagrangian coordinates”)

$$g'' \circ g^{-1} = -\nabla p,$$

where $p = p(t, x) \in \mathbb{R}$ is the pressure field and $\nabla p = (\partial_{x_1} p, ..., \partial_{x_d} p)$. The minimization problem will be subsequently called “Shortest Path Problem” (SPP).

The basic local existence and uniqueness theorem for the SPP is due to Ebin and Marsden. If $h$ and $I$ are sufficiently close in a sufficiently high order Sobolev norm, then there is a unique shortest path. In the large, uniqueness can fail for the SPP. For example, in the case when $D$ is the unit disk, $h(z) = -z$, the SPP has two solutions $g(t, z) = ze^{it}$ and $g(t, z) = ze^{-it}$, where complex notations are used.

In 1985, A. Shnirelman found, in the case $D = [0, 1]^3$, a class of data for which the SPP cannot have a (classical) solution. These data are those of form

$$h(x_1, x_2, x_3) = (H(x_1, x_2), x_3),$$

where $H$ is an area preserving mapping of the unit square, i.e. an element of $G([0, 1]^2)$, for which

$$\delta_{[0, 1]^3}(I, h) < \delta_{[0, 1]^2}(I, H) < +\infty.$$  

(This means that, although $h$ is really a two dimensional map, genuinely 3D motions perform better to reach $h$ from $I$ than purely 2D motions.)

Shnirelman also proved that $S([0, 1]^d)$ is the right completion of $G([0, 1]^d)$ for the geodesic distance $\delta$, for all dimension $d \geq 3$. (Notice that $S([0, 1]^d)$ is the...
$L^2$ completion of $G([0, 1]^d)$ for all $d \geq 2$. So, the case $d = 2$ is very peculiar.)

In such situations, a complete existence and uniqueness result for the SPP was obtained in [Br2], provided the pressure field is considered as the right unknown and not the path $t \to g(t)$ itself.

**Theorem 1.2** Let $h \in S([0, 1]^3)$ of form $h(x_1, x_2, x_3) = (H(x_1, x_2), x_3)$ with $H \in S([0, 1]^2)$. Then there is a unique vector-valued measure $\nabla p(t, x_1, x_2)$ such that, for each sequence of curves $t \in [0, 1] \to g_n(t) \in G([0, 1]^3)$ labelled by $n \in \mathbb{N}$ and satisfying

$$A_{[0,1]^3}(g_n) \to \frac{1}{2}\delta_{[0,1]^3}^2(I, h), \quad ||g_n(1) - h||_{L^2([0,1]^3)} \to 0,$$

as $n \to \infty$, then (in the distributional sense)

$$g_n'' \circ g_n^{-1} \to -\nabla p.$$

In other words, the acceleration field of all minimizing sequences converge to $-\nabla p$ which uniquely depends on data $h$. The proof relies on an appropriate concept of generalized solutions (related to “Young’s measures” [Y2], [1a], [DM], [She]) that describe the oscillatory behaviour of the $(g_n)$ as $n \to +\infty$ and reduces the SPP to a convex minimization problem. (See [Br2] for more details.) More precisely, the associated measures

$$c_n(t, x, a) = \delta(x - g_n(t, a)), \quad m_n(t, x, a) = \partial_t g_n(t, a) \delta(x - g_n(t, a)),$$

have cluster points $(c, m)$ that have the following properties:

1) $m$ is absolutely continuous with respect to $c$ and its vector-valued density $v(t, x, a)$ is $c-$ square integrable;

2) $c$ and $v$ do not depend on $x_3$ and $v_3 = 0$;

3) $c$ and $v$ solve

$$\partial_t c + \nabla_x (cv) = 0, \quad \partial_t (cv) + \nabla_x (cv \otimes v) + c\nabla_x p = 0, \quad (1.1)$$

where the product $cv \nabla_x p$ has to be properly defined (in a way related to the work of Zheng and Majda [ZM]). Equations (1.1) are obtained as the optimality equations of the convexified minimization problem. Therefore, it is a priori unclear they have any physical meaning as evolution equations. However, they correspond, up to a change of unknown, to the hydrostatic limit of the Euler equations, obtained from the Euler equations by neglecting the vertical acceleration term, namely:

$$Kg'' \circ g^{-1} = -\nabla p,$$

where $K$ is the singular diagonal matrix $(1, 1, 0)$. These hydrostatic (or “shear flow”) equations are widely used for atmosphere and ocean circulation modelling, as the building block of the so-called “primitive equations”. However, they are more singular than the Euler equations and their mathematical analysis is very limited, as discussed in [Li]. Conditional well-posedness and derivation from the Euler equations have been established in [Br3] and [Gr].
Remarks

An intriguing question is whether or not the uniqueness of $\nabla p$ can be proved by more classical tools even in the case when $H \in G([0, 1]^2)$ can be connected to the identity map by a classical shortest path on $G([0, 1]^2)$.

Since $S([0, 1]^3)$ is the right completion of $G([0, 1]^3)$ with respect to the geodesic distance, one could expect the SPP to have a solution in $S([0, 1]^3)$ for all data $h$. This is not true. An example of such a data is $h(x_1, x_2, x_3) = (1 - x_1, x_2, x_3)$. Only generalized flows, as discussed in [Br2], can describe shortest paths in full generality.

Example of generalized solutions

Explicit examples of non trivial generalized shortest paths can be computed either numerically or exactly. Let us just quote a typical example, when $D$ is the cylinder $\{(z, s) = (x_1, x_2, s), |z| \leq 1, 0 \leq s \leq 1 \}$ and $h(z, s) = (-z, s)$. Then, the classical SPP has two distinct solutions $g_+(t, z, s) = (e^{i\pi t} z, s)$ and $g_-(t, z, s) = (e^{-i\pi t} z, s)$, with the same pressure field $p = \pi^2 |z|^2/2$, where complex notations are used on the disk $|z| \leq 1$. (Notice that there is no motion along the vertical axis $s$.) Trivial generalized solutions are obtained by mixing these two solutions. However, a non trivial generalized solution exists and can be described as follows. For each fluid particle initially located at $(z, s)$, the elevation $s$ stays unchanged and the initial horizontal position $z$ splits up along a circle of radius $(1 - |z|^2)^{1/2} \sin(\pi t)$, with center $z \cos(\pi t)$, that moves across the unit disk and shrinks down to the point $-z$ as $t = 1$. In addition, each particle is accelerated by the pressure field $p = \pi^2 |z|^2/2$, as expected from the theory.

2. Polar factorization of maps and the Monge-Ampère equation

A way to define approximate geodesics on $G = G(D)$ is to introduce a penalty parameter $\epsilon > 0$ and to consider the formal (hamiltonian) dynamical system in the Hilbert space $H = L^2(D, \mathbb{R}^d)$

$$\epsilon^2 \frac{d^2}{dt^2} M + \frac{\delta}{\delta M} \left( \frac{d^2_{\mu}(M, G)}{2} \right) = 0, \quad (2.1)$$

where the unknown $M$ is a curve $t \to M(t) \in H$, $\delta/\delta M$ denotes the gradient operator in $H$, and

$$d_{\mu}(M, G) = \inf_{g \in G} ||M - g||_{\mu} \quad (2.2)$$

is the distance in $H$ between $M$ and $G$, where $||.||_{\mu}$ is the Hilbert norm of $H$. This approach is related to Ebin’s slightly compressible flow theory [EZ], and is a natural extension of the theory of constrained finite dimensional mechanical systems [RU, AK]. Notice that the approximate geodesic equation is sensitive only to the $L^2$ closure of $G(D)$, which is, in the case $D = [0, 1]^d$, $d \geq 2$, the entire semi-group $S(D)$ [Ne]. As the penalty parameter $\epsilon$ goes to zero, we expect that for appropriate initial
data, typically for \( M(t = 0) = I \) and \((d/dt)M(t = 0) = \nu_0\), where \( \nu_0 \) is a smooth divergence free vector field on \( D \) tangent to the boundary, the time dependent map \( M \) converges to a geodesic curve on \( G \). Because of the classical properties of the distance function in a Hilbert space, for each point \( M \in H \) for which there exists a unique closest point \( \pi_S(M) \) on \( S(D) \), we have
\[
\frac{\delta}{\delta M} \left( \frac{d^2(M, G)}{2} \right) = M - \pi_S(M).
\]
(2.3)
Thus, we can formally write the approximate geodesic equation
\[
\epsilon^2 \frac{d^2}{dt^2} M + M - \pi_S(M) = 0.
\]
(2.4)
Therefore, it is natural to address the following variational problem, that we call the Closest Point Problem (CPP)

**Definition 2.1** Given \( M \in L^2(D, \mathbb{R}^d) \), find \( h \in S(D) \) that minimizes
\[
\frac{1}{2} \int_D |M(x) - h(x)|^2 dx.
\]
The solution of the CPP is given by the Polar Factorization theorem for maps

**Theorem 2.2** Let \( M : D \rightarrow \mathbb{R}^d \) be an \( L^2 \) map such that the probability measure
\[
\rho_M(x) = \int_D \delta(x - M(a)) da
\]
is a Lebesgue integrable function on \( D \). Then, there exists a unique closest point \( \pi_S(M) \) on \( S(D) \) and there is a Lipschitz convex function \( \Phi \) on \( \mathbb{R}^d \) such that
\[
\pi_S(M)(a) = (\nabla \Phi)(M(a)), \quad \text{a.e. } a \in D.
\]
In addition, \( \Phi \) is a weak solution, in a suitable sense, of the Monge-Ampère equation
\[
\det(\partial_{xx} \Phi(x)) = \rho_M(x).
\]
Thus, the Monge-Ampère equation, which is usually considered as a non variational geometric PDE related to the concept of Gaussian curvature, also is the optimality equation of a variational problem closely linked to the Euler equations of incompressible inviscid fluids. In addition, the Polar Factorization theorem can be seen as a nonlinear version of the Helmholtz-Hodge decomposition theorem for vector fields which asserts that any \( L^2 \) vector field on \( D \) can be written in a unique way as the (orthogonal) sum of the gradient of a scalar field and a divergence free field tangent to \( \partial D \). Shortly after [Br1], Caffarelli [Ca] established several regularity results for the Polar Factorization. For example, provided \( D \) is smooth and strictly convex, any smooth orientation preserving diffeomorphism \( M \) of \( D \) has a unique Polar Factorization with smooth factors, and \( \pi_S(M) \) belongs to \( G(D) \). More recently, McCann [Mc] generalized the Polar Factorization theorem when \( D \) is a compact Riemannian manifolds.
3. Optimal Transportation Theory

In [Br1], the solution of the CPP problem is based on the Optimal Transportation Theory (OTT). The OTT was introduced by Monge in 1781 [Mo] to solve an engineering problem and renewed by Kantorovich near 1940 [Ka] in the framework of Linear Programming and Probability Theory [RR]. In modern words, this amounts to look for a probability measure \( \mu \) on a given product measure space \( A \times B \), with prescribed projections on \( A \) and \( B \), that minimizes

\[
\int_{A \times B} c(x, y) d\mu(x, y),
\]

where the “cost function” \( c \geq 0 \) is given on \( A \times B \). The CPP roughly corresponds to the case when \( A = B = D \), \( c(x, y) = |M(x) - y|^2 \) and each projection of \( \mu \) is the (normalized) Lebesgue measure on \( D \). The connexion established in [Br1] between the OTT and the Monge-Ampère equation, enhanced by Caffarelli’s regularity theory [Ca], introduced OTT as an active field of research in nonlinear PDEs. Let us first quote the work of Evans-Gangbo [Ev] to solve the original Monge problem with PDE techniques, related to the Eikonal equations, and the recent contributions of Ambrosio, Caffarelli, Feldman, McCann, Trudinger, Wang. (A first attempt was made by Sudakov [Su] with purely probabilistic tools.) Let us next point out the importance of OTT for modelling purposes in Applied Mathematics. First of all, it is fair to say that the OTT and the Monge-Ampère equation were already key ingredients in Cullen and Purser’s theory of semi-geostrophic atmospheric flows, which goes back to the early 1980s and preceded our Polar Factorization theorem (see references in [CNP]). Next, Jordan-Kinderlehrer-Otto [JKO], using OTT, established that the heat equation can be seen as a gradient flow for Boltzmann’s entropy functional. More systematically, Otto [Ot] showed how the OTT confers a natural Riemannian structure to sets of Probability measures and recognized a large class of dissipative PDEs as gradient flows of various functionals for such Riemannian structures. Examples of such PDEs are porous media equations, lubrication equations, granular flow equations, etc... Let us also mention that OTT has become a powerful tool in Calculus of Variations (through McCann’s concept of displacement convexity [Mc]) and Functional Analysis, where all kind of functional inequalities (Minkowski, Brascamp-Lieb, Log Sobolev, Bacry-Emery, etc,...) can be established through OTT arguments, as shown, in particular, by Barthe [Ba], McCann [Mc], Otto, Villani [OV]. Let us finally mention that [BB] has provided for the OTT a formulation different from the Monge-Kantorovich one, by introducing an interpolation variable (which was already present in McCann’s concept of displacement convexity). This point of view is useful for both numerical [BB] and theoretical purposes, in particular, by allowing non trivial generalizations of the OTT related to section [B].

4. Approximate geodesics and Electrodynamics
Let us go back to the approximate geodesic equation (2.4) that can be (formally) written, thanks to the Polar Factorization theorem,

$$\partial_t M(t, a) + (\nabla \phi)(t, M(t, a)) = 0, \quad \det(I - \epsilon^2 \partial_{xx} \phi(t, x)) = \rho_M(t, x)$$

(4.1)

(where $\phi(t, x)$ stands for $\epsilon^{-2}(|x|^2/2 - \Phi(t, x))$). A formal expansion about $\epsilon = 0$ leads, as expected, to the Euler equation (written in Lagrangian coordinates) at the zero order and, at the next order (and exactly as $d = 1$), to

$$\partial_t M(t, a) + (\nabla \phi)(t, M(t, a)) = 0, \quad \epsilon^2 \Delta \phi(t, x) = 1 - \rho_M(t, x),$$

(4.2)

which can be equivalently written as

$$\partial_t f + \xi.\nabla_x f - \nabla_x \phi.\nabla_\xi f = 0, \quad \epsilon^2 \Delta \phi = 1 - \int fd\xi$$

(4.3)

by introducing the “phase density”

$$f(t, x, \xi) = \int_D \delta(x - M(t, a))\delta(\xi - \partial_t M(t, a))da.$$

This system is nothing but the Vlasov-Poisson system that describes the classical non-relativistic motion of a continuum of electrons around a homogeneous neutralizing background of ions through Coulomb interactions.

So, the approximate geodesic equation, which can be written as a “Vlasov-Monge-Ampère” (VMA) system,

$$\partial_t f + \xi.\nabla_x f - \nabla_x \phi.\nabla_\xi f = 0, \quad \det(I - \epsilon^2 \partial_{xx} \phi) = \int fd\xi$$

(4.4)

can be interpreted as a (fully nonlinear) correction of the Vlasov-Poisson system for small values of $\epsilon$. Recently, Loeper [Lo] has shown that the VMA system has local smooth solutions and global weak solutions. Loeper has also proved that the Euler equations and the Vlasov-Poisson system correctly describe the asymptotic behaviour of the VMA system as $\epsilon \to 0$. The asymptotic analysis is based on the so-called modulated energy method already used in [Br5] to derive the Euler equations from the Vlasov-Poisson system.

Notice that, thanks to the substitution of the Monge-Ampère equation (a fully non-linear elliptic PDE) for the classical Poisson equation, the “electric” field $\nabla_\phi(t, x)$ is pointwise bounded by the diameter of $D$ divided by $\epsilon^2$, independently on the initial conditions. In particular, point charges do not create unbounded force fields as in classical Electrodynamics.

5. A caricature of Coulomb interaction

The approximate geodesic equation (2.4) can be easily discretized in space by substituting i) for $D$ a discrete set of $N$ “grid” points equally spaced in $D$, say $A_1, ..., A_N$, ii) for $H$ the euclidean space $\mathbb{R}^{dN}$, iii) for $G$ the discrete set of all
sequences \((A_{\sigma_1}, ..., A_{\sigma_N}) \in \mathbb{R}^{dN}\) generated by permutations \(\sigma\) of the first \(N\) integers, while keeping unchanged equation (2.4). (Note that such a discretization using permutations cannot be so easily defined for the Euler equations, which formally correspond to the limit case \(\epsilon = 0\).) Then \(\mathcal{M}(t) = (M_1(t), ..., M_N(t))\) can be interpreted as a set of \(N\) harmonic oscillators

\[
\epsilon^2 \frac{d^2}{dt^2} M_\alpha + M_\alpha - A_{\sigma_\alpha}(t) = 0, \tag{5.1}
\]

where the time dependent permutation \(\sigma(t)\) is subject to minimize, at all time \(t\), the total potential energy

\[
\sum_{\alpha=1}^{N} |M_\alpha(t) - A_{\sigma_\alpha}|^2. \tag{5.2}
\]

This system can be seen as a collection of \(N\) springs linking each particle \(M_\alpha\) to one of the fixed particle \(A_\beta\) according to a dynamical pairing \(\beta = \sigma_\alpha(t)\) maintaining the bulk potential energy at the lowest level. There is some ambiguity in the definition of this formal hamiltonian system for which the hamiltonian is given by

\[
\frac{1}{2} \sum_{\alpha=1}^{N} \frac{dM_\alpha}{dt}^2 + \inf_{\sigma} \frac{1}{2\epsilon^2} \sum_{\alpha=1}^{N} |M_\alpha - A_{\sigma_\alpha}|^2. \tag{5.3}
\]

In particular, \(\sigma(t)\) is not uniquely defined at each time \(t\) for which several particles have the same position. However, the potential is the sum of a quadratic and a Lipschitz concave functions of \(M\). So its gradient has linear growth at infinity and its second order partial derivatives are locally bounded measures. This is enough, according to recent results by Lions and Bouchut [Bo, Li2], to ensure that unique global solutions are well defined for Lebesgue almost every initial data \(M_\alpha(0), \# M_\alpha(0), \alpha = 1, ..., N\). As expected, the limit \(N \to +\infty, \epsilon \to 0\) (provided \(N\) goes fast enough to \(+\infty\)), leads to the Euler equation, as proven in [Br4]. From the electrostatic point of view, the dynamical system describes a nonlinearly cutoff Coulomb interaction between \(N\) electrons (with positions \(M_\alpha\)) and a background of \(N\) motionless ions (with fixed positions \(A_\alpha\)).

6. Generalized extremal surface equations and Electrodynamics

As seen above, the approximate geodesic equation (4.1)—which has been introduced as a natural geometrical approximation to the Euler equations—turns out to be a model for electrostatic interaction with a non-linearly cutoff Coulomb potential. This feature is somewhat reminiscent of the Born-Infeld non-linear theory of the electromagnetic field [BI] (see also [BDLL, GZ,...]). Therefore, one may try to design from similar geometric ideas a non-linearly cutoff theory for classical Electrodynamics. An attempt is made in [Br6]. Instead of considering springs linking two particles of opposite charges we rather consider (with a more space-time oriented...
Some Geometric PDEs Related to Hydrodynamics and Electrodynamics 769

point of view) surfaces \((t, s) \rightarrow X(t, s)\) spanning curves \(t \rightarrow X_-(t)\) and \(t \rightarrow X_+(t)\) followed by two particles of opposite charge, so that \(X(s = -1, t) = X_- (t)\) and \(X(s = 1, t) = X_+(t)\), \(s \in [-1, 1]\) standing for the “interpolation” parameter between the two trajectories. Just by prescribing \((t, s) \rightarrow (t, s, X(t, s))\) to be an extremal surface in the 5 dimensional Minkowski space \((t, s, x_1, x_2, x_3)\) (with signature \((-++++)\)), we get the building block of the model. In other words, the individual Action of each surface is

\[
\int \sqrt{1 + |\partial_s X|^2 - |\partial_t X|^2} - |\partial_s X \times \partial_t X|^2} dt ds,
\]

(6.1)

(which is basically the Nambu-Goto Action of classical string theory). Next, we associate with \(X\) a “generalized surface” \((\rho, J, E, B)\) (or more precisely a “cartesian current” in the sense of [GMS]) defined by

\[
\rho(t, s, x) = \delta(x - X(t, s)), \quad J(t, s, x) = \partial_t X(t, s) \delta(x - X(t, s)),
\]

(6.2)

\[
E(t, s, x) = \partial_s X(t, s) \delta(x - X(t, s)),
\]

(6.3)

\[
B(t, s, x) = \partial_s X(t, s) \times \partial_t X(t, s) \delta(x - X(t, s))
\]

(6.4)

and subject to compatibility conditions

\[
\partial_s \rho + \nabla E = 0, \quad \partial_t \rho + \nabla J = 0, \quad \partial_t E - \partial_s J - \nabla \times B = 0.
\]

(6.5)

In terms of \((\rho, J, E, B)\) the Action of \(X\) can be written as

\[
K(\rho, J, E, B) = \int \sqrt{\rho^2 - J^2 + E^2 - B^2}.
\]

(6.6)

Varying this Action under constraint \((6.5)\) leads to a system of evolution equations for \((\rho, J, E, B)\) (see [Br6] for an explicit form), that we can call “generalized extremal surface equations” (GESE). They enjoy (at least in the simplest cases when the solutions depend on one or two space variables) many interesting properties: hyperbolicity, linear degeneracy of all fields \([BDLL]\), symmetries between \(t\) and \(s\), \(J\) and \(E\) etc... From the GESE, we can derive through various (formal!) limiting process 1) the Born-Infeld and the Maxwell equations, as \((\rho, J)\) are prescribed at \(s = -1\) and \(s = +1\) (in which case there is no coupling between charged particles and the electromagnetic field), 2) the Vlasov-Born-Infeld and the Vlasov-Maxwell equations as \((E, B) = 0\) is prescribed at \(s = -1\) and \(s = +1\) (which corresponds to a free boundary condition \(\partial_s X = 0\) for an individual surface and yields a full coupling between charged particles and the electromagnetic field). In spite of the possible physical irrelevance of the GESE, their mathematical analysis (global existence, uniqueness, etc...), and the rigorous derivation from them of classical models, such as the Vlasov-Maxwell equations, are, in our opinion, challenging problems in the field of non-linear PDEs.
