Mining the deep Red-Sea brine pool microbial community for anticancer therapeutics

Luke Esau 1, Guishan Zhang 2,3, Sunil Sagar 1, Ulrich Stingl 3,4, Vladimir B. Bajic 1 and Mandeep Kaur 1,5*

Abstract

Background: Microbial species in the brine pools of the Red Sea and the brine pool-seawater interfaces are exposed to high temperature, high salinity, low oxygen levels and high concentrations of heavy metals. As adaptations to these harsh conditions require a large suite of secondary metabolites, these microbes have a huge potential as a source of novel anticancer molecules.

Methods: A total of 60 ethyl-acetate extracts of newly isolated strains from extreme environments of the Red-Sea were isolated and tested against several human cancer cell lines for potential cytotoxic and apoptotic activities.

Results: Isolates from the Erba brine-pool accounted for 50% of active bacterial extracts capable of inducing 30% or greater inhibition of cell growth. Among the 60 extracts screened, seven showed selectivity towards triple negative BT20 cells compared to normal fibroblasts.

Conclusion: In this study, we identified several extracts able to induce caspase-dependent apoptosis in various cancer cell lines. Further investigations and isolation of the active compounds of these Red Sea brine pool microbes may offer a chemotherapeutic potential for cancers with limited treatment options.

Keywords: Deep Red-Sea, Triple negative breast cancer, Brine pools, Anticancer

Background

The hallmarks of cancer, which categorises the survival and proliferative mechanisms of cancer cells, was first described by Hanahan and Weinberg [1]. Although these aspects of cancer are well studied, and even with the advances in personalized medicine for patient tailored treatment, there still exists cancer forms for which limited treatment options are available. Breast cancer, the most prevalent cancer in women globally, has an estimated 1.67 million cases diagnosed in 2012 [2]. Women of Arab [3] and African descent [4] present breast cancer at an earlier age, have more aggressive tumour types with a high prevalence of triple negative breast cancer. Penta-negative tumours (i.e., negative for the estrogen and progesterone receptors, EGFR, HER2, and cytokeratin 5/6) have also been reported in Saudi women [5]. In our previous seminal investigations [6, 7], we reported the anticancer potential of extracts obtained from brine-pool microbes. Most of these extracts were active against estrogen receptor positive (ER+) breast cancer cells. Since the triple-negative type of breast cancer is a more aggressive form and as currently no therapies are available, we aimed to identify new sources of anticancer compounds that can pave the way to develop novel therapies for triple negative breast cancer.

Approximately 60% of current anticancer therapeutics are derived from natural products, including, for example, marine-derived compounds such as cytarabine, trabectedin, eribulin, and dolastatins [8]. A review by Agrawal et al. [9] described nonribosomal peptides isolated from marine microbes having anticancer activity while in a research article Neelam et al. [10] discovered a marine halo-alkalophilic bacteria species possessing anti breast cancer activity. This evidence supports the

pursuit of mining marine environments for the discovery of new anticancer agents. Twenty-five (mostly) anaerobic deep-sea brine pools with extremely high salt concentrations have been reported in the Red Sea. Multi-extremophilic microbes that inhabit these environments are not only adapted to high salinity (4–26%), but also to elevated temperature, low oxygen concentrations, and high concentrations of heavy metals [11–14]. These extreme marine environmental conditions favour the production of secondary metabolites and thus potentially unique and potent natural compounds. Extremophilic marine bacterial species from these environments, therefore, present a unique opportunity for discovering novel anticancer compounds [6, 7] that address the ever-changing need for improved chemotherapeutic drugs.

This study reports on anticancer activity of extracts from bacterial isolates from different habitats around brine pools within the Red Sea. We screened a total of 60 extracts against seven cell lines representing colorectal carcinoma, fibrosarcoma, breast carcinoma, cervical carcinoma, neuroblastoma, and normal cell lines. After initial screening, active extracts (> 30% growth inhibition) were selected for testing in selected cell lines to investigate if apoptotic activities were moderated by caspases (executors of apoptotic cell death).

Methods

Field sampling

The inoculum for microbial isolations were collected during a cruise between Oct 16 and Nov 3 2011 as described in Sagar et al. [7].

Source of bacterial isolates

Sixty bacterial strains were isolated from different habitats in or around the brine pools (Table 1). While the deep-sea brine pool habitats differ in their physicochemical characteristics [15], several studies showed that all of these environments harbour high microbial diversity and biomass.

PCR amplification

DNA extraction, PCR amplification, and bioinformatics analyses of 16S rRNA genes from biomass of bacterial strains was performed according to Sagar et al. [7]. Sequences were deposited in Genbank, and accession numbers are listed in Table 1.

Bacterial biomass

The inocula were streaked using three different media types as described by (Sagar et al. 2013 [6, 7]). These solidified media types were supplemented with either 10% or 15% or 20% or 26% NaCl (w/v) before autoclaving to mimic salt concentrations in their original habitat. All incubations were done in a Binder incubator (Type BD53, Binder, Tuttlingen, Germany). Strains reported here were isolated under oxic conditions (air, 21% O₂) and atmospheric pressure (1 atm) described elsewhere [16, 17]. To collect biomass, all strains were grown for 2 to 3 weeks with constant agitation at 30 °C in 5.01 of Marine Broth (Difco) supplemented with the respective concentration of NaCl. Bacterial biomass was harvested and ethyl acetate extracts were prepared according to Sagar et al. [6, 7].

Cell culturing

BJ (Fibroblast), HCT (Colorectal adenocarcinoma), HT-1080 (Fibrosarcoma), MCF-7 (Breast Adenocarcinoma), IMR-32 (Neuroblastoma), BT20 (Breast Adenocarcinoma), and HeLa (Cervical carcinoma) were obtained from the American Type Cell Culture Collection (ATCC, Manassas, VA). The cells were cultured in DMEM (Dulbecco’s Modified Eagle’s Medium) containing 10% FCS (Foetal calf serum), and streptomycin (100 μg/mL) and penicillin (100 U/mL) in a 37 °C incubator supplying 5% CO₂.

MTT assay

2.5 × 10³ cells were seeded per well in 384-well culture plates and treated with 200 μg/mL marine bacterial extracts for 48 h. Growth inhibitory effects of extracts were estimated by an MTT (3-(4, 5-Dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide) assay as previously described [7]. A microtiter plate reader (BMG Labtech-PHERAstar FS, Germany) was used to measure the OD (optical density) at 595 nm and the results were analyzed using Microsoft Office Excel®.

APOPercentage assay

Cells were seeded in quadruplicates in 96 well plates at a density of 5 × 10³ cells per well in 90 μL of media. After 24 h, 200 μg/mL extracts were added to the cells for 48 h with, while 30 min treatment with 10 mM H₂O₂ was used as a positive control. The cells were lifted and stained with the APOPercentage dye (Biocolor, UK), and analysed as described previously [18].

Caspase-3/7 activity assay

2.5 × 10³ cells were seeded in 20 μL of media in 384-well plates and allowed to settle overnight. Five microliters of extract (200 μg/mL) was added and further incubated for 48 h. Manufacturer’s instructions were followed to estimate Caspase-3/7 activity by using ApoTox-Glo kit (Promega) and the luminescence was measured using BMG LabtechPHERAstar FS (Germany). The results were normalized to cell viability (measured using MTT assay).

**Statistical analysis**

The samples (untreated vs. treated) were compared by using Student’s t-test and statistical significance was noted at \( p < 0.05 \). A Z-score of \( \geq 0.6 \) indicated robustness of assays [15].

**Results**

**Taxonomic classification of microbes isolated from the Red Sea**

Most bacteria isolated from the four brine pools Erba, Discovery, Kebrat, and Nereus were closely related to known and well described halophilic species within *Proteobacteria* and *Archaea* (Table 1).

**Anticancer activities of isolates in a panel of cell lines**

A total of 60 extracts isolated from bacterial cultures from the four brine pools Erba, Discovery, Kebrat, and Nereus were screened for anticancer activity by determining cell growth inhibition through MTT assay (Table 2). Extracts induced varying levels of growth inhibition and were classified into five groups - empty circle (< 30%), quarter-moon (> 30 and < 40%), half-moon (> 40 and < 60%), three-quarter-moon (> 60 and < 80%) and full-moon (> 80%). The skin fibroblast cell line BJ was used as a normal cell line control for screening anticancer activity of the extracts. BJ cell growth was inhibited by approximately 50% of extracts while the growth of neuroblastoma cell line IMR-32 remained largely insensitive to the treatment. Interestingly, the growth of the triple negative breast cancer cell line BT20 was sensitive to the majority of the extracts. Further analysis revealed that the majority of bacterial isolates inducing active growth inhibition (above 30%) in this study set were isolated from the Erba brine pool (Fig. 1). Figure 1 represents the distribution of active bacterial extracts inducing greater than 30% growth inhibition found across the brine-pools.

**Apoptosis as mode of anticancer activity**

We assessed phosphatidylserine exposure in cancer cells treated with selected microbial extracts using APOPercentage assay and monitored change in caspase-3/7 activity to determine if extracts induced apoptosis. For this purpose, the extracts inducing > 30% growth inhibition were selected for apoptosis screening (Table 3). Due to the availability of limited amount of microbial extracts, we performed apoptosis and caspase-3/7 activity assays only on extracts active in breast cancer, cervical cancer, and fibrosarcoma cell lines. Again, BJ cells were used as a control to identify extracts with selective anticancer activity. Extracts induced apoptosis in all cell lines. However four (ZGT118, XI10, 7 and 13), six (ZGT118, XI10, 13, 16, 30 and 55), one (9), and three (10, 15 and 22) extracts selectively induced apoptosis in MCF-7, BT20, HeLa and H T-1080 cells compared to BJ cells, respectively. The extract number 7 was only active against MCF-7 cells, whereas extracts 16 and 55 were selectively active against BT20 cells when the apoptosis-

inducing potential of these extracts was compared among all five cell lines (Table 3).

A Caspase-3/7 activity assay was employed to gain insights into the type of apoptosis occurring, namely caspase-dependent or caspase-independent (Fig. 2a-d). The caspase-3/7 results showed a clear trend that a caspase-independent mechanism was mostly responsible for BJ cell death. Extract number 7 induced caspase-dependent apoptosis in MCF-7 cells but had no adverse effect on BJ cell death despite it inducing slight growth inhibition in BJ cells making it a promising drug candidate for future work. Extract number 19 induced caspase-dependent apoptosis in MCF-7, HeLa, and HT1080 cells but not in BJ cells, even though BJ cells stained positive for phosphatidylserine exposure by APOPercentage assay (Table 3). Caspase-3/7 activity increased in BT20 cells compared to BJ cells in response to extracts ZGT108, ZGT114, 12, 24, 37, 54 and 55. HeLa cells and HT1080 cells displayed significantly increased caspase-3/7 activation in response to extracts 4 and 19, respectively (Fig. 2). Interestingly, extract number 55 showed selectivity towards BT20 cells by inhibiting its growth and inducing apoptosis via caspase-3/7, neither of which was observed for BJ cells.

Discussion
As a follow-up from our previous studies [6, 7], we screened extracts from 60 marine bacteria isolated from brine pools of the Red Sea. We would like to emphasize that in our previous two investigations, we could only find extracts active against MCF-7 (ER+) cells, but the current study reports anticancer activities of the extracts isolated from the Red Sea brine-pool harboring bacteria against fibrosarcoma, cervical cancer and particularly BT20 (triple negative) cancer cells. Primary cytotoxicity screening of all extracts against seven cell lines representing five different cancers enabled us to broadly identify potential anticancer extracts from deep-sea microbes. All extracts were also screened against one normal fibroblast cell line (BJ) to further identify those who exhibited selectivity for cancer, but not normal cells.

We investigated whether the brine-pool location had any correlation with anticancer activity induced by the bacterial isolates. Of all isolates from the respective brine-pools, we found that about 50% of all isolates collected from Erba Deep (located at a depth of 2395 m), showed greater than 30% growth inhibition (Fig. 1). The most closely related validly described species to these strains are (Table 1): Chromohalobacter israelensis, Salinivibrio siamensis, Idiomarina seosinensis, Pseudoalteromonas scarrageenovora, Pontibacillus halophilus, and Alteromonas macleodii. Our previous work [7] has reported anticancer activity of Chromohalobacter israelensis in HeLa cells. A PubMed search did not reveal even a single article that describes the anticancer activity of any of the other five bacterial species. This highlights the fact that the microbes found in the deep-sea brine pools of the Red Sea (especially Erba Deep) may have unique anticancer compounds that can be explored in the future to develop new drugs.

Apoptosis assays (APOPercentage and caspase-3/7 activity) confirmed that several of these selected (showing > 30% cell growth inhibition) extracts induced apoptotic cell death in cancer cell lines. This secondary screening process identified the extracts that selectively targeted a specific type of cancer via apoptotic cell death. We further investigated if extracts from a particular bacterial species have anticancer activity towards a specific cell line. Intriguingly, all three extracts (10, 15 and 22) that specifically inhibited the growth of fibrosarcoma cells (HT-1080) belonged to strains that were closely related to Salinivibrio costicola, Salinivibrio sharmensis, and Salinicola salaries, respectively, showing an enrichment of genus Salinivibrio. It would be interesting in future to investigate Salinivibrio extracts against other sarcomas as well. In MCF-7 cells, two out of four most active extracts (X110 and 13) belonged to Pseudoalteromonas mariniglutinosa. This bacterial species had not been tested so far for anticancer activities (PubMed search). Secondary metabolites isolated from Pseudoalteromonas sp. off the coast of Brazil were reported to have potent anticancer activity against a leukemic and melanoma cell line, and the active compound, prodigiosin, was shown...
Table 3: The percentage apoptotic cell death induced by selected extracts in various cell lines. Heat map of extracts (200 μg/ml) inducing apoptosis in one normal (BJ) and selected cancer cell lines after 48 h treatment.

Fig. 2 Caspase 3/7 Activity in cells treated with bacterial extract. Normal skin fibroblast cell line BJ and four cancer cell lines MCF-7, BT20, HeLa and HT1080 were treated with 200 μg/ml bacterial extract for 48 h (a-d). Fold change in Caspase-3/7 activity relative to untreated was determined as per manufacturer’s instructions and students t-test was used to determine significance where * indicates p < 0.05.
to be selective for cancers overexpressing ErbB-2 [19]. In BT20 cells, extracts (16 and 55) showed selective cell death, and these extracts belong to species Halomonas hamiltonii and Alcanivorax dieseloei, respectively, none of which have ever been shown to have anticancer activity before. Our observation that Halomonas sp. and Alteromonas sp. contributed to the majority of growth inhibition may be attributed to their ability to produce molecules including exopolysaccharides (EPSs) and Dithioloypyrrolone (DTP), respectively. Exopolysaccharides (heterogeneous polymers) isolated from Halomonas stenophila and Halomonas smyrnensis induced pro-apoptotic effects against human T-lymphoma cells [20] and breast cancer MCF-7 cells [21]. Alteromonas sp. are also well known for producing dithioloypyrrolone (DTP) molecules, which are known potent natural antibiotics; DTP obtained FDA approval as topical antibiotic Bactroban® (GlaxoSmithKline) [22]. Not surprising, DTP also exhibits potent anticancer activity. These classes of anti-biotic or polysaccharide type molecules most probably explain the anticancer activity we observed in this study.

In conclusion, our study has identified several microbial species that have the potential to kill selectively cancer cells, and interestingly many of these species have never been previously tested for their anticancer activities. Here, we provide seminal baseline data pinpointing which bacterial species and brine-pools should be targeted for future investigations to isolate anticancer compounds. This work is of particular importance for triple negative breast cancer therapeutic development as no drug exists till date that can effectively cure this aggressive form of breast cancer. Testing of these marine extracts against penta-negative breast cancer cells should be of great interest to future studies.

**Abbreviations**

DMEM: Dulbecco's Modified Eagle's Medium; DTP: Dithioloypyrrolone; ER: Estrogen receptor; FCS: Foetal calf serum; MTT: 3-(4, 5-Dimethylthiazol-2-yil)-2, 5-diphenyltetrazolium bromide; OD: Optical density; PS: Phosphatidylserine

**Acknowledgements**

Authors want to thank Dr. Andre Antunes and Dr. Tyas Hikmawan for collecting samples.

**Authors’ contributions**

LE and MK performed biological testing experiments and wrote the manuscript. LE analysed data and compiled tables/figures. SS prepared the extracts for biological evaluations and planned the study with MK. GZ grew the strains in large batches, isolated the strains and provided the taxonomic classification. US planned the exhibition and the cultivation experiments along with the writing of the manuscript. VBB provided general coordination of the study. All authors read and approved the final manuscript.

**Funding**

Authors thank SEDCO for funding this research.

**Availability of data and materials**

All 16S rRNA gene sequences of newly isolated strains from this study have been deposited in Genbank. Please refer to Table 1 for accession numbers.
