I. INTRODUCTION

Anisotropic interactions are at the heart of many physical systems, such as the atomic nucleus, heteronuclear molecules, or ultracold dipolar atoms. The anisotropy has a marked influence on their scattering and bound state properties. Additionally, confining a system to layers often leads to exotic effects and is thought to be a crucial ingredient for the elusive theory of high-Tc superconductivity [1].

Heteronuclear molecules are a prime candidate for studying low-energy anisotropic scattering in a controlled manner. Notably, they possess a large permanent dipole moment. Further, several species have now been cooled to ultracold temperatures [2]. These conditions give rise to an anisotropic dipole-dipole interaction (DDI), which can be controlled by external fields [3]. For example, an electric field polarizes the molecules. However, if the DDI dominates the three-dimensional (3D) dynamics, the gas becomes unstable [4]. Perpendicular polarization. The interlayer binding, e.g., of two \(^{6}\)Li\(^{40}\)K molecules, is deeper than thermal energies in typical ultracold experiments over a range of polarization angles.

We consider two particles interacting via a 2D potential \(V(r)\). In the center-of-mass frame the scattered state depends on both the relative vector \(r = r(\cos\phi, \sin\phi)\) between the two particles and the incoming wave vector \(k = k(\cos\xi, \sin\xi)\). Consequently, we expand the dimensionless wave function in partial waves for both vectors: \(\Psi(k, r) = \frac{1}{2\pi} \sum_{m = -\infty}^{\infty} \psi_{mn}(kr) e^{im\phi} e^{-i\xi \phi}\). Inserting this expansion into the radial Schrödinger equation of the two particles results in

\[
\left[ \frac{d^2}{dr^2} - \frac{m^2 - 1/4}{r^2} + k^2 \right] \psi_{mn}(k, r) = \sum_{m'} V_{mn'}(r) \psi_{m'n}(k, r). \quad (1)
\]

Here, \(k = \sqrt{E2\mu\Delta^2/\hbar^2}\) is the collision momentum at energy \(E\), \(\mu\) is the reduced mass, and \(\Delta\) is the unit of length. The matrix elements of the potential are \(V_{mn}(r) = \mu\Delta^2 \int \frac{d^2r}{4\pi} d\phi e^{im\phi} e^{-i\xi \phi} V(r)\).

Different physical solutions of Eq. (1), such as scattering or bound states, fulfill different boundary conditions. For our proposed formalism, we expand all physical states \(\psi_{mn}\) in a set of regular solutions of Eq. (1), \(\phi_{mn}\), with well-defined boundary conditions. Specifically, we require that these regular solutions behave at the origin as \(\lim_{r \to 0} \phi_{mn}(r)/j_m(kr) = \delta_{mn}\). Here, we have defined the scaled Bessel functions \(J_m(x) = \sqrt{\pi x/2} j_m(x)\) and \(y_m(x) = \sqrt{\pi x/2} y_m(x)\), where \(J_m\) and \(Y_m\) are Bessel functions of the first and second kind, respectively. For 2D scattering, these scaled Bessel functions are the equivalent of the Riccati-Bessel functions familiar from 3D scattering [12]. Our choice of the boundary condition fixes the freedom in the expansion coefficients of the regular solution and its derivative [13].

We assume \(\lim_{r \to 0} r^2 V_{mn}(r) = 0\) and \(\lim_{r \to \infty} r V_{mn}(r) = 0\). Because of the latter, at large distances solutions of Eq. (1) are proportional to the scaled Hankel functions \(h_{mn}^\pm(x) = j_m(x) \pm i y_m(x)\). This motivates us to expand the regular solutions as

\[
\phi_{mn}(k, r) = \frac{1}{2} \left[ h_m^+(kr) f_{mn}^+(k, r) + h_m^-(kr) f_{mn}^-(k, r) \right]. \quad (2)
\]

We insert this expansion into Eq. (1) and require that \(h_m^+(kr) \partial_r f_{mn}^+(k, r) + h_m^-(kr) \partial_r f_{mn}^-(k, r) = 0\). This condition re-
duces the Schrödinger equation to the first order equation
\[ \partial_r f_{mn}^+(k, r) = \pm \frac{\hbar^2}{ik} \sum_{m'} V_{mm'}(r) \phi_{m'n}(k, r) \]  
(3)
for the coefficients \( f_{mn}^+(k, r) \). The formal solution of Eq. (3) is
\[ f_{mn}^+(k, r) = \delta_{mn} + \frac{1}{ik} \int_0^r d'r h_m^+(kr') \sum_{m'} V_{mm'}(r') \phi_{m'n}(k, r'). \]  
(4)
Here, we have fixed the integration constants so that \( f_{mn}^+(k, \infty) \) exhibits the correct high-energy behavior [13].

II. BOUND STATES

A weak 2D potential supports bound states if \( \int d^2r V(r) \leq 0 \) [11]. Using the coefficients \( f_{mn}^+ \), we locate bound states in the following way. For \( \Im(k) > 0 \) [\( \Im(k) < 0 \)] \( f_{mn}^+(k, r) \) converges as \( r \to \infty \) because the right-hand side of Eq. (3) vanishes sufficiently quickly for the assumed long-range behavior of the potential [13]. The functions \( f_{mn}^+(k) = \lim_{r \to \infty} f_{mn}^+(k, r) \) are the Jost functions familiar from general scattering theory [12, 13]. Introducing the matrices \( F^\pm(k) = [f_{mn}^\pm(k)] \) we locate bound states by finding momenta \( k_b = i|k_b| \) on the positive imaginary axis with vanishing determinant, i.e.,
\[ \det[F^-(k_b)] = 0 \iff \sum_m f_{mn}^-(k_b) c_n(k_b) = 0. \]  
(5)
If the determinant of the Jost matrix \( F^- \) vanishes, then there exists a nonvanishing set of coefficients \( c_n \) fulfilling the right-hand side of Eq. (5). Moreover, at large distances the solutions \( u_m(k_b, r) = \sum_n \phi_{mn}(k_b, r) c_n(k_b) \) vanish exponentially because \( u_m(k_b, r) = O[h_m^+(kr)] = O[e^{-|k_b|r}] \to 0 \). Therefore, \( u_m(k_b, r) \) describes a bound state. Its binding energy is
\[ E_b = -|k_b|^2 \text{ in units of } h^2/2\mu\Delta^2. \]

Now we are going to derive an approximate expression for the binding energy in a weak anisotropic 2D potential \( V(r) = V_0 V(r) \), where \( V_0 \) characterizes the strength of the potential. First, we introduce the explicit expression for the regular solutions \( \phi_{mn}(k, r) = \int_0^r d'r g_m(kr) \phi_{m'n}(k, r') \sum_{m'} V_{mm'}(r') \phi_{m'n'}(k, r') \), where \( g_m(k, r', r') = k^{-1} \int_0^r d'r' g_m(kr, r') \sum_{m'} V_{mm'}(r') \phi_{m'n'}(k, r') \) is the free Green’s function of Eq. (1) [14]. Furthermore, the regular solutions of the Schrödinger Eq. (1) for \( k = 0 \) are \( \phi_{mn}(r) = r^{\pm n/2} \sum_{m'} V_{mm'}(r') \phi_{m'n'}(r') \), where \( g_0(r, r') = \sqrt{rr'} \ln(r'/r) \) and \( g_{m \neq 0}(r, r') = \sqrt{rr'/2m} \) \( (r/r')^m - (r'/r)^m \) are corresponding free Green’s functions. Now \( \sqrt{\Gamma(k/2)^{n+1/2}} / \phi_{mn}(r)/n! \) is the expansion of \( \phi_{mn}(k, r) \) to leading order in \( k \). In Eq. (4) we replace \( \phi_{mn}(k, r) \) and the scaled Hankel function by their respective leading order terms. Then we insert the asymptotic form of this approximation for \( f_{mn}^+(k, r) \) into the left-hand side of Eq. (5). The result is \( \det[F^-(k)] = A|\ln(k)| + \gamma - \ln(2) - \pi/2 + 1 - B = 0 \), where \( \gamma \) is the Euler-Mascheroni constant. Solving this for \( k \) we find the binding energy
\[ E_b = -4e^{-2\gamma - 2\pi/2}. \]  
(6)
We obtain the power series \( A = \sum_{j=1}^\infty A^{(j)} \) and \( B = \sum_{j=1}^\infty B^{(j)} \) by expanding \( \phi_{mn}(r) \) into a power series of the potential strength \( V_0 \), where \( j \) indicates the power of \( V_0 \). For a general (possibly anisotropic) 2D potential the leading terms of these series, including all partial waves, are given by
\[ A^{(1)} = -\int_0^\infty dr V_00(r), \]  
(7)
\[ A^{(2)} = \int_0^\infty dr V_00(r) \int_0^r dr' r' \ln \left( \frac{r'}{r} \right) V_00(r'), \]  
(8)
\[ -\sum_{m \neq 0} \frac{1}{2m} \int_0^\infty dv V_00(r) \int_0^r dr V_{mm}(r) \]  
\[ + \sum_{m \neq 0} \int_0^\infty dr \sqrt{r} V_{mm}(r) u_{m0}^{(1)}(r), \]  
(9)
\[ B^{(1)} = \int_0^\infty dr \ln V_00(r) - \sum_{m \neq 0} \frac{1}{2m} \int_0^\infty dv V_{mm}(r), \]  
(10)
\[ B^{(2)} = -\int_0^\infty dr \ln V_00(r) \int_0^r dr' r' \ln \left( \frac{r'}{r} \right) V_00(r'), \]  
\[ + \sum_{m \neq 0} \frac{1}{2m} \int_0^\infty dv \ln V_{mm}(r) \int_0^r dr V_{mm}(r) \]  
\[ - \sum_{m \neq 0} \int_0^\infty dr \sqrt{r} V_{mm}(r) u_{m0}^{(1)}(r), \]  
\[ + \sum_{m \neq 0} \frac{1}{2m} \int_0^\infty dv \ln V_{mm}(r) u_{m0}^{(1)}(r) + \sum_{m \neq 0} V_{mm}(r) w_{m}(r) + \sum_{n \neq 0} \sum_{m \neq n} V_{mm}(r) u_{mn}^{(1)}(r). \]  
Here, \( u_{mn}^{(1)}(r) = \int_0^r dr' r^{1/2-n} g_{mn}(r, r') r^{1/2-n} g_{mn}(r, r') \) and \( w_{m}(r) = \int_0^r dr' r^{1/2+2m} g_{mn}(r, r') V_{mm}(r') - \) \( \sum_{n \neq 0, m} (1/2n)^{1/2+n} \int_0^r dr' r^{1/2+2m} V_{mm}(r') \). We can calculate systematically higher order terms by expanding \( \det[F^-(k)] \) to higher orders in \( V_0 \). Very recently, Volosniev et al. [9] also found such an expansion of the binding energy by solving the 2D Schrödinger equation directly for bound states.

For concreteness let us now consider two polarized dipoles trapped in two parallel layers separated by a distance \( \Delta \). We define the \( z \) axis to be perpendicular and the \( x-y \) plane to be parallel to the layers. Without loss of generality, we assume that the dipoles are polarized within the \( x-z \) plane at an angle \( \theta \) from the \( z \) axis. They interact via the interlayer potential
\[ V(r) = V_0 \frac{r^2 + 1 - 3(r \cos \theta \sin \phi + \cos \phi \delta^2)}{(r^2 + 1)^{3/2}}. \]  
(11)
Here, \( r = r(\cos \phi, \sin \phi) \) is the dimensionless projected vector between the dipoles in polar coordinates (in units of \( \Delta \)) and \( V_0 = \mu d^2/2n\hbar^2 \varepsilon_0 \Delta \) is the interaction strength in units of...
\( h^2 / 2\mu\Delta^2 \), with \( \epsilon_0 \) the electric constant and \( d \) the electric dipole moment (for magnetic dipoles \( V_0 = \mu_0\mu B^2 / 2\pi h^2 \Delta^2 \) with \( \mu_0 \) the magnetic constant and \( \mu_0 \) the magnetic dipole moment). The potential fulfills \( A(1) = 0 \) and \( \int d^2r V(r) = 0 \) so that at least one bound state exists for all polarization angles. For \( \theta = 0 \), this potential reduces to the central case discussed in Refs. [6, 7]. Using Eq. (6) and expanding \( S \) to fourth and second order, respectively, we recover the binding energy for perpendicular polarization given in Ref. [7].

In Fig. 1 we plot the binding energy of the lowest lying interlayer bound states in the potential (11) as a function of the polarization angle and interaction strength \( V_0 \). The latter approximation remains valid up to moderate \( V_0 \) as long as \( |E_b| \ll 1 \). The insets show densities of the bound states at the indicated polarization angles and \( V_0 = 10 \). The dark circles indicate the radius of one layer distance \( \Delta \).

Next we focus on the 2D scattering problem, for which \( k \) is real. Then the functions \( f_{mn}(k, r) \) attain the finite limit \( f_{mn}^{\pm}(k) = \lim_{r \to \infty} f_{mn}^{\pm}(k, r) \) because the right-hand side of Eq. (3) vanishes at \( r \to \infty \). In order to capture the mixing of different partial waves, it is necessary to calculate the full S-matrix. We express the partial wave components of the scattering solution as a linear combination \( \Psi_{mn}(k, r) = \sum \Phi_{mn'}(k, r) c_{mn'}(k) \) of the regular solutions, Eq. (2). Asymptotically, we replace \( f_{mn}^{\pm}(k, r) \) in \( \Phi_{mn}(k, r) \) with the Jost functions \( f_{mn}^{\pm}(k) \). On the other hand, the general asymptotic scattering wave function in 2D is \( \Psi(k, r) \to |e^{ikr} + a(k, r) r e^{ikr} |2\pi | \), where \( a(k, r) \) is the scattering amplitude. We match the two asymptotic expressions for the scattering wave functions by expanding the first exponential in \( \Psi(k, r) \) in terms of scaled Hankel functions. This way, we extract the S-matrix

\[
S(k) = F^+(k) [F^-(k)]^{-1}
\]

and the coefficients \( c_{mn}(k) = |F^{-}(k)|_{mn}^{-1} \). If the potential \( V(r) \) is central, \( S(k) \) is diagonal, with elements \( e^{i\delta_m(k)} \) and \( \delta_m(k) \) the \( m \)-th partial wave phase shift.

Let us now derive approximate expressions for the phase shifts of anisotropic 2D scattering at low energies. First we introduce an iterative solution for the coefficients \( f_{mn}^{\pm}(k, r) = \sum_{j=0}^{\infty} f_{mn}^{\pm(j)}(k, r) \) as a power series in the potential strength \( V_0 \). From Eq. (4) and the expression for \( \Phi_{mn}(k, r) \) we obtain

\[
f_{mn}(k, r) = \pm \sum_{j=0}^{\infty} f_{mn}^{j}(k, r) \sum_{m'} V(r) \Phi_{m'n}(k, r') \delta_{mn'}(k, r') \text{ and } f_{mn}^{(j+1)}(k, r) = f_{mn}^{(j)}(k, r) \delta_{mn} \text{ with } \Phi_{mn}(k, r) = j_{n}(kr) \delta_{mn}. \]

In the remainder of this section, we consider low scattering energies such that only up to two partial waves \( \ell \) and \( \ell' \) dominate the properties of the S-matrix. The phase shifts are given by the expressions

\[
\delta_{\ell}(k) = \text{Im} S_{\ell\ell}/\text{Re} S_{\ell\ell}, \text{ where } S_{\ell\ell} \text{ is a diagonal matrix element of } S \text{ and } \delta_{\ell} \text{ is obtained by replacing } \ell \to \ell'.
\]

By inserting Eq. (12) we obtain the phase shifts from
the Jost matrix $F^-$ since $F^+ = F^-$ for real $k$. Then
\[ \tan 2\delta_{\ell}(k) \approx 2 \frac{\text{Im} s_{\ell\ell}}{\text{Re} s_{\ell\ell}} \] (13)

with $s_{\ell\ell} = S_{\ell\ell}|\text{det}(F^-)|^2$. Using terms $f_{nm}^{(j)}$ up to second order and expanding $s_{\ell\ell}$ to second order in $V_0$ we find
\[ \text{Im}(S_{\ell\ell}) = - I_{j\ell,j\ell}^{(1)} + I_{j\ell,j\ell}^{(1)} I_{j\ell,j\ell}^{(1)} - I_{j\ell,j\ell}^{(1)} I_{j\ell,j\ell}^{(1)} + 2 I_{j\ell,j\ell}^{(2)} I_{j\ell,j\ell}^{(2)} \] \[ \text{Re}(S_{\ell\ell}) = 1 + \sum_{m=\ell} \left[ -2 I_{j\ell,jm}^{(1)} + 2 I_{j\ell,jm}^{(2)} + I_{j\ell,jm}^{(1)} I_{j\ell,jm}^{(1)} - 2 I_{j\ell,jm}^{(1)} I_{j\ell,jm}^{(1)} + 4 I_{j\ell,jm}^{(1)} I_{j\ell,jm}^{(1)} \right]. \]

Here, $E_b$ is the binding energy, Eq. (6).

In Fig. 2(a) we plot the s-wave phase shift of two dipoles with $V_0 = 1$ interacting across two layers as a function of the collision momentum $k$, e.g., $^{40}$K$^{87}$Rb with different spins at $\Delta = 200$ nm. The sharp increase of the s-wave phase shift at $k \to 0$ ($\Theta = 0, \pi/6$) is a consequence of the very weakly bound states. If $\delta_0$ dominates in Eq. (13), a very small binding energy leads to a phase jump in $\delta_0$ close to $k = 0$. Since the binding energy decreases strongly with increasing polarization angle, expression (15) describes the scattering of mainly in-plane polarization only at unrealistically small collision energies. On the other hand, the weak potential approximation (13) describes the numerics excellently at all considered momenta. It fails at large potential strengths $V_0 \gg 1$ and small momenta. For large momenta $k \gg 1$ this approximation becomes identical with the Born approximation (14). In Fig. 2(b) we observe that the s-wave phase shift can vary strongly with the polarization angle at small moments. The phase jump is caused by a weakly bound state at $\Theta \simeq 0.3 \pi$ [see Fig. 1(a)]. This variability should be observable in the scattering of polar molecules. The bound-state approximation (15) describes this behavior qualitatively even for such moderately large potential strengths as long as $k \ll 1$. The difference is mainly due to neglecting higher order partial waves in Eq. (15). For a small potential strength $V_0 \ll 1$ our approximation Eq. (13) describes scattering excellently at all polarizations. We find that this approximation remains valid even at moderately large potential strengths $V_0 \lesssim 3$ at higher energies $k^2 \gtrsim 1$.

IV. CONCLUSIONS

We have proposed a framework for calculating scattering and bound state properties for anisotropic 2D potentials. Our method generalizes the Jost formalism known from 3D scattering. We have derived systematic approximations for the scattering phase shifts and binding energy at low to moderate potential strengths. For weak potentials we have recovered a second-order Born approximation. The central equation (3) is also well-suited for numerical computations.

We have applied our method to polar molecules trapped in a bilayer and polarized along an arbitrary direction. We find that absolute energies of $^6$Li$^{88}$K interlayer bound states are larger than their thermal energy in ultracold experiments even for nonperpendicular polarization. The s-wave phase shift of molecules with moderate or large DDI exhibits a strong dependence on the polarization angle. These results are important, e.g., for the BEC-BCS crossover in fermionic polar molecules in bilayers [15, 16]. Varying the direction of the external polarizing field should influence the crossover from interlayer pair condensation to BCS pairing.
