June 30, 2003

Abstract

Let \( V_\Gamma \) be a lattice periodic potential and \( A \) and \( \phi \) external electromagnetic potentials which vary slowly on the scale set by the lattice spacing. It is shown that the Wigner function of a solution of the Schrödinger equation with Hamiltonian operator
\[
H = \frac{1}{2}(\Delta_x - A(x))^2 + V_\Gamma(x) + \phi(x)
\]
propagates along the flow of the semiclassical model of solid states physics up to an error of order \( \varepsilon \). If \( \varepsilon \)-dependent corrections to the flow are taken into account, the error is improved to order \( \varepsilon^2 \). We also discuss the propagation of the Wigner measure. The results are obtained as corollaries of an Egorov type theorem proved in [PST3].

1 Introduction

One of the central questions of solid state physics is to understand the motion of electrons in the periodic potential which is generated by the ionic cores. While this problem is quantum mechanical, many electronic properties of solids can be understood already in the semiclassical approximation [AsMe, Ko, Za]. One argues that for suitable wave packets, which are spread over many lattice spacings, the main effect of a periodic potential \( V_\Gamma \) on the electron dynamics corresponds to changing the dispersion relation from the free kinetic energy \( E_{\text{free}}(p) = \frac{1}{2} p^2 \) to the modified kinetic energy \( E_n(p) \) given by the \( n \)th Bloch function. Otherwise the electron responds to slowly varying external potentials \( A, \phi \) as in the case of a vanishing periodic potential. Thus the semiclassical equations of motion are
\[
\dot{r} = \nabla E_n(\kappa), \quad \dot{\kappa} = -\nabla \phi(r) + \dot{r} \times B(r)
\]
where \( \kappa = k - A(r) \) is the kinetic momentum and \( B = \text{curl} A \) is the magnetic field. (We choose units in which the Planck constant \( \hbar \), the speed \( c \) of light, and
the mass \( m \) of the electron are equal to one, and absorb the charge \( e \) into the potentials.) The corresponding equations of motion for the canonical variables \((r, k)\) are generated by the Hamiltonian

\[
H_{\text{sc}}(r, k) = E_n(k - A(r)) + \phi(r),
\]

where \( r \) is the position and \( k \) the quasi-momentum of the electron. Note that there is a semiclassical evolution for each Bloch band separately. The distinction between the canonical variable \( k \), the Bloch- or quasi-momentum, and the kinetic momentum \( \kappa = k - A(r) \) is often not made explicit in the physics literature. It is, however, crucial for the formulation of the precise connection between the semiclassical equations of motion \((1)\) and the underlying Schrödinger equation \((4)\).

In [PST3] we use adiabatic perturbation theory in order to understand on a mathematical level how these semiclassical equations emerge from the underlying Schrödinger equation \((3)\).

In \((3)\) the potential \( V_{\Gamma} : \mathbb{R}^d \to \mathbb{R} \) is periodic with respect to some regular lattice \( \Gamma \) generated through the basis \( \{\gamma_1, \ldots, \gamma_d\}, \gamma_j \in \mathbb{R}^d \), i.e.

\[
\Gamma = \{ x \in \mathbb{R}^d : x = \sum_{j=1}^{d} \alpha_j \gamma_j \text{ for some } \alpha \in \mathbb{Z}^d \}
\]

and \( V_{\Gamma}(\cdot + \gamma) = V_{\Gamma}(\cdot) \) for all \( \gamma \in \Gamma \). The lattice spacing defines the microscopic spatial scale. The external potentials \( A(\varepsilon y) \) and \( \phi(\varepsilon y) \), with \( A : \mathbb{R}^d \to \mathbb{R}^d \) and \( \phi : \mathbb{R}^d \to \mathbb{R} \), are slowly varying on the scale of the lattice, as expressed through the dimensionless scale parameter \( \varepsilon, \varepsilon \ll 1 \). In particular, this means that the external fields are weak compared to the fields generated by the ionic cores, a condition which is satisfied for real metals even for the strongest external electrostatic fields available and for a wide range of magnetic fields, cf. [AsMe], Chapter 12.

Note that the external forces due to \( A \) and \( \phi \) are of order \( \varepsilon \) and therefore have to act over a time of order \( \varepsilon^{-1} \) to produce finite changes, which is taken as the definition of the macroscopic time scale. Hence, one is interested in solutions of \((3)\) for macroscopic times. The macroscopic space-time scale \((x, t)\) is defined through \( x = \varepsilon y \) and \( t = \varepsilon s \). With this change of variables Equation \((3)\) reads

\[
i \varepsilon \partial_t \psi^\varepsilon(x, t) = \left( \frac{1}{2} (-i \varepsilon \nabla_x - A(x))^2 + V_{\Gamma}(x/\varepsilon) + \phi(x) \right) \psi^\varepsilon(x, t)
\]

with initial conditions \( \psi^\varepsilon(x) = \varepsilon^{-d/2} \psi(x/\varepsilon) \). If \( V_{\Gamma} = 0 \), then the limit \( \varepsilon \to 0 \) in Equation \((4)\) is the usual semiclassical limit with \( \varepsilon \) replacing \( \hbar \).

The problem of deriving \((1)\) from the Schrödinger equation \((3)\) in the limit \( \varepsilon \to 0 \) has been attacked along several routes. In the physics literature \((1)\) is
usually accounted for by constructing suitable semiclassical wave packets. We refer to [134, 135, 136]. The few mathematical approaches to the time-dependent problem (4) extend techniques from semiclassical analysis, as the Gaussian beam construction [137, 138, 139], or Wigner measures [140, 141, 141a].

In this note we explain and elaborate on recent results from [142]. In [142] we derived (1) from (4) for quite general external potentials $A$ and $\phi$. The construction is based on the space-adiabatic perturbation theory developed in [142, 143], see also [144] and the contribution of G. Nenciu in the present volume. The crucial observation is that the step from (3) to (1) involves actually two approximations. Semiclassical behavior can only emerge if a Bloch band is separated by a gap from the other bands and thus the corresponding subspace decouples adiabatically from its orthogonal complement. The dynamics inside this adiabatic subspace is governed by an effective Hamiltonian $\hat{h}_{\text{eff}}$, which is explicitly given as an $\epsilon$-pseudodifferential operator. Eventually, the semiclassical limit of $\hat{h}_{\text{eff}}$ leads to (1).

Hence (3) needs to be reformulated as a space-adiabatic problem. This has been done first in [145] for the case of zero magnetic field and then in [142] for general electric and magnetic fields. The results obtained in this way constitute not only the derivation of the semiclassical model (1) in this generality, but they allow to compute systematically higher order corrections in the small parameter $\epsilon$. It turns out that the electron acquires a $k$-dependent electric moment $A_n(k)$ and magnetic moment $M_n(k)$. If the $n$th band is nondegenerate (and isolated) with Bloch eigenfunctions $\psi_n(k, x)$, the electric dipole moment is given by the Berry connection

$$A_n(k) = i \langle \psi_n(k), \nabla \psi_n(k) \rangle,$$

and the magnetic moment by the Rammal-Wilkinson phase

$$M_n(k) = \frac{1}{2} \langle \nabla \psi_n(k), \times (H_{\text{per}}(k) - E(k)) \nabla \psi_n(k) \rangle.$$

Here $\langle \cdot, \cdot \rangle$ is the inner product in $L^2(\mathbb{R}^d/\Gamma)$ and $H_{\text{per}}(k)$ is $H$ of (8) with $\phi = 0 = A$ for fixed Bloch momentum $k$. Note that $E_n$, $A_n$ and $M_n$ are $\Gamma^*$-periodic functions of $k$, where $\Gamma^*$ is the lattice dual to $\Gamma$. Hence one can as well think of them as functions on the domain $M^* = \mathbb{R}^d/\Gamma^*$, the first Brillouin zone.

The semiclassical equations of motion including first order corrections read

$$\dot{r} = -\nabla_k \left( E_n(k) - \epsilon B(r) \cdot M_n(k) \right) - \epsilon \dot{k} \times \Omega_n(k),$$

$$\dot{k} = -\nabla_r \left( \phi(r) - \epsilon B(r) \cdot M_n(k) \right) + \dot{r} \times B(r),$$

with $\Omega_n(k) = \nabla \times A_n(k)$ the curvature of the Berry connection.

In order to state the precise connection between the semiclassical equations of motion (1) resp. their refined version (7) and the underlying Schrödinger equation (4), we need some more notation. Let

$$H^\epsilon = \frac{1}{2}(-i\epsilon \nabla_x - A(x))^2 + V_T(x/\epsilon) + \phi(x)$$

(8)
be the Hamiltonian of (4). Under the following assumption on the potentials, which will be imposed throughout, \( H^\varepsilon \) is self-adjoint on \( H^2(\mathbb{R}^d) \). Here \( C^\infty_b(\mathbb{R}^d) \) denotes the space of smooth functions which are bounded together with all their derivatives.

**Assumption.** Let \( V_\Gamma \) be infinitesimally bounded with respect to \(-\Delta\) and assume that \( \phi \in C^\infty_b(\mathbb{R}^d, \mathbb{R}) \) and \( A_j \in C^\infty_b(\mathbb{R}^d, \mathbb{R}) \) for any \( j \in \{1, \ldots, d\} \).

To each isolated Bloch band \( E_n \) there corresponds an associated almost invariant band-subspace \( \Pi^\varepsilon_n L^2(\mathbb{R}^d) \). The orthogonal projector \( \Pi^\varepsilon_n \) onto this subspace is constructed in [PST3]. Only for states which start in this subspace and thus, by construction, remain there up to small errors, the semiclassical equations of motion (7) can have any significance.

The flow of the dynamical system (7) is denoted by \( \Phi^t_\varepsilon: \mathbb{R}^{2d} \to \mathbb{R}^{2d} \) or in canonical coordinates \( (r,k) = (r,\kappa + A(r)) \) by

\[
\Phi^t_\varepsilon(r,k) = \left( \Phi^t_{\varepsilon r}(r,k - A(r)), \Phi^t_{\varepsilon \kappa}(r,k - A(r)) + A(r) \right).
\]

The existence of the smooth family of diffeomorphisms \( \Phi^t_\varepsilon \) is not completely obvious from (7) alone, but follows from the Hamiltonian formulation of (7) presented in the next section.

**Notation.** Throughout this paper we will use the Fréchet space

\[
\mathcal{C} = C^\infty_b(\mathbb{R}^{2d}),
\]

equipped with the metric \( d_\mathcal{C} \) induced by the standard family of semi-norms

\[
\|a\|_\alpha = \|\partial^\alpha a\|_\infty, \quad \alpha \in \mathbb{N}_0^{2d},
\]

and the subspace of \( \Gamma^* \)-periodic observables

\[
\mathcal{C}_{\text{per}} = \{a \in \mathcal{C}: a(r,k + \gamma^*) = a(r,k) \; \forall \gamma^* \in \Gamma^*\}.
\]

We abbreviate \( d_\mathcal{C}(a) := d_\mathcal{C}(a,0) \).

The main result of [PST3] on the semiclassical limit of (4) is the following Egorov type theorem.

**Theorem 1.** Let \( E_n \) be an isolated, non-degenerate Bloch band. For each finite time-interval \( I \subset \mathbb{R} \) there is a constant \( C < \infty \), such that for all \( a \in \mathcal{C}_{\text{per}} \) with Weyl quantization \( \hat{a} = a(x, -i\varepsilon \nabla x) \) one has

\[
\left\| \left( e^{iH^\varepsilon t/\varepsilon^2} \hat{a} e^{-iH^\varepsilon t/\varepsilon^2} - \hat{a} \circ \Phi^t_\varepsilon \right) \Pi^\varepsilon_n \right\|_{B(L^2(\mathbb{R}^d))} \leq \varepsilon C d_\mathcal{C}(a) \tag{9}
\]

and

\[
\left\| \Pi^\varepsilon_n \left( e^{iH^\varepsilon t/\varepsilon^2} \hat{a} e^{-iH^\varepsilon t/\varepsilon^2} - \hat{a} \circ \Phi^t_\varepsilon \right) \Pi^\varepsilon_n \right\|_{B(L^2(\mathbb{R}^d))} \leq \varepsilon^2 C d_\mathcal{C}(a). \tag{10}
\]
Remark. The corresponding statement in [PST] does not make explicit the
dependence of the error on the observable \( a \). However, the more precise version
formulated here is a standard consequence of the Calderon-Vaillancourt theorem
and the fact that composition with \( \Phi^t_\varepsilon \) is a continuous map from \( C \) into itself.

Remark. On an abstract level the distinction between the functions \( \Phi^t_\varepsilon \)
and \( \Phi^t_\varepsilon \) is immaterial, since both functions express the same dynamical flow in two
systems of coordinates. However, the distinction between the systems of co-
ordinates becomes important when the quantization is considered. The Weyl
quantization appearing in (9) and (10) must be understood with res pect to the
system of coordinates \( (r,k) \). Analogous consideration hold true for formulas
involving a Wigner transform, as in Corollary 2.

The main objective of this note is to elaborate on Theorem 1 in order to
make contact to alternative approaches and results on the semiclassical limit of
\( (4) \). This are, as mentioned above, Wigner functions \([GMMP, BFPR, BMP]\)
semiclassical wave packets \([Lu, Ko, Za, SuNi]\) and WKB-type solutions of \((4)\)
\([Bu, GRT, DGR]\). We focus on the semiclassical transport of Wigner functions
and Wigner measures in the following. Before we do so, it is worthwhile to first
examine the equations of motion (7) in some more detail.

2 The refined semiclassical equations of motion

The dynamical equations (7), which define the \( \varepsilon \)-corrected semiclassical model,
can be written as

\[
\frac{\dot{r}}{\kappa} = \nabla_\kappa H_{sc}(r, \kappa) - \varepsilon \dot{\kappa} \times \Omega_n(\kappa),
\]

\[
\kappa = -\nabla_r H_{sc}(r, \kappa) + \dot{r} \times B(r)
\]

with

\[
H_{sc}(r, \kappa) := E_n(\kappa) + \phi(r) - \varepsilon \mathcal{M}_n(\kappa) \cdot B(r).
\]

We shall show that (11) are the Hamiltonian equations of motion for (12)
with respect to a suitable \( \varepsilon \)-dependent symplectic form \( \Theta_{B,\varepsilon} \). The semiclassical
equations of motion (7) are defined for arbitrary dimension \( d \). However, to simplify
presentation, we use a notation motivated by the vector product and the duality
between 1-forms and 2-forms for \( d = 3 \), which we briefly explain.

Notation. If \( d \neq 3 \), then \( B, \Omega_n \) and \( \mathcal{M}_n \) are 2-forms with components

\[
B_{ij}(r) = \partial_i A_j(r) - \partial_j A_i(r),
\]

\[
\Omega_{ij}(k) = \partial_i A_j(k) - \partial_j A_i(k)
\]

and

\[
\mathcal{M}_{ij}(k) = \text{Re} \frac{1}{2} \langle \partial_k \psi_n(k), (H_{per} - E)(k) \partial_j \psi_n(k) \rangle.
\]

For \( d = 3 \) a 2-form \( B_{ij}(r) \) is naturally associated with the vector \( B_k(r) = \epsilon_{kij} B_{ij}(r) \). We use the convention that summation over repeated indices is
implicit. Then in (7) the inner product $B \cdot M$ refers to the product of the associated vectors and we generalize the notation to arbitrary dimension $d$ using the inner product of 2-forms defined through

$$B \cdot M := *^{-1}(B \wedge *M) = \sum_{j=1}^{d} \sum_{i=1}^{d} B_{ij} M_{ij},$$

where $*$ denotes the Hodge duality induced by the euclidian metric. In the same spirit for a vector field $w$ and a 2-form $F$ the generalized "vector product" is

$$(w \times F)_j := (*^{-1}(w \wedge *F))_j = \sum_{i=1}^{d} w_i F_{ij},$$

where the duality between 1-forms and vector fields is used implicitly. ♦

We keep fixed the system of coordinates $z = (r, \kappa)$ in $\mathbb{R}^{2d}$ for the following. The standard symplectic form $\Theta_0 = \Theta_0(z)_{lm} dz_m \wedge dz_l$, where $l, m \in \{1, \ldots, 2d\}$, has coefficients given by the constant matrix

$$\Theta_0(z) = \left( \begin{array}{cc} 0 & -\mathbb{I} \\ \mathbb{I} & 0 \end{array} \right),$$

where $\mathbb{I}$ is the identity matrix in $\text{Mat}(d, \mathbb{R})$. The symplectic form, which turns (11) into Hamilton’s equation of motion for $H_{sc}$, is given by the 2-form $\Theta_{B, \epsilon} = \Theta_{B, \epsilon}(z)_{lm} dz_m \wedge dz_l$ with coefficients

$$\Theta_{B, \epsilon}(r, \kappa) = \left( \begin{array}{cc} B(r) & -\mathbb{I} \\ \mathbb{I} & \epsilon \Omega_n(\kappa) \end{array} \right).$$

(13)

For $\epsilon = 0$ the 2-form $\Theta_{B, \epsilon}$ coincides with the magnetic symplectic form $\Theta_B$ usually employed to describe in a gauge-invariant way the motion of a particle in a magnetic field ([MaRa], Section 6.6). For $\epsilon$ small enough, the matrix (13) defines a symplectic form, i.e. a closed non-degenerate 2-form.

With these definitions the corresponding Hamiltonian equations are

$$\Theta_{B, \epsilon}(z) \dot{z} = dH_{sc}(z),$$

or equivalently

$$\left( \begin{array}{ccc} B(r) & -\mathbb{I} & \nabla_r H(r, \kappa) \\ \mathbb{I} & \epsilon \Omega_n(\kappa) & \nabla_{\kappa} H(r, \kappa) \end{array} \right) \left( \begin{array}{c} \dot{r} \\ \dot{\kappa} \\ \nabla_r H(r, \kappa) \end{array} \right) = 0,$$

which agrees with (11). We notice that this discussion remains valid if $\Omega_n$ admits a potential only locally, as it happens generically for magnetic Bloch bands.

The symplectic structure is therefore determined by the magnetic field $B(r)$ and by the curvature of the Berry connection $\Omega(k)$, which encodes relevant information about the geometry of the Bloch bundle $\psi_n(k, \cdot) \mapsto k \in M^*$. One can show that, whenever the Hamiltonian $H_{per}$ has time-reversal symmetry one
has that $\Omega_n(-k) = -\Omega_n(k)$. Moreover, if the lattice $\Gamma$ has a center of inversion, then $\Omega_n(-k) = \Omega_n(k)$. Thus, the two symmetries together imply that $\Omega_n(k)$ vanishes pointwise. But there are many crystals which do not have a center of inversion and, more important, in the presence of a strong uniform magnetic field the time-reversal symmetry is broken. The latter is the typical setup to describe the Quantum Hall Effect, a situation in which the curvature of the Berry connection plays a prominent role. Indeed, the equations of motion (7) provide a simple semiclassical explanation of the Quantum Hall Effect. Let us specialize (7) to two dimensions and take $B(r) = 0$, $\phi(r) = -E \cdot r$, i.e. a weak driving electric field and a strong uniform magnetic field with rational flux. Then, since $\kappa = k$, the equations of motion become $\dot{r} = \nabla_k E_n(k) - \mathcal{E} \cdot \Omega_n(k)$, $k = \mathcal{E}$, where $\Omega_n$ is now scalar, and $\mathcal{E} \cdot \Omega_n$ is $\mathcal{E}$ rotated by $\pi/2$. We assume initially $k(0) = k$ and a completely filled band, which means to integrate with respect to $k$ over the first Brillouin zone $M^*$. Then the average current for band $n$ is given by

$$j_n = \int_{M^*} dk \dot{r}(k) = \int_{M^*} dk (\nabla_k E_n(k) - \mathcal{E} \cdot \Omega_n(k)) = -\mathcal{E} \cdot \int_{M^*} dk \Omega_n(k).$$

$\int_{M^*} dk \Omega_n(k)$ is the Chern number of the magnetic Bloch bundle and as such an integer, cf. [TKNN]. Further applications related to the semiclassical first order corrections are the anomalous Hall effect [JNM] and the thermodynamics of the Hofstadter model [GaAv].

### 3 Semiclassical transport of Wigner functions

Theorem 11 provides a semiclassical description of the evolution of observables. The most direct way to turn it into a description for the semiclassical evolution of states is via duality, i.e. via the Wigner function. Recall that according to the Calderon-Vaillancourt theorem there is a constant $C < \infty$ depending only on the dimension $d$ such that for $a \in C$ one has

$$| \langle \psi, \hat{a} \psi \rangle_{L^2(\mathbb{R}^d)} | \leq C d_C(a) \| \psi \|^2. \quad (14)$$

Hence, the map $C \ni a \mapsto \langle \psi, \hat{a} \psi \rangle \in \mathbb{C}$ is continuous and thus defines an element $w^\psi_\psi$ of the dual space $C'$, the Wigner function of $\psi$. Writing

$$\langle \psi, \hat{a} \psi \rangle := \langle w^\psi_\psi, a \rangle_{C', C} =: \int_{\mathbb{R}^{2d}} dq dp \; a(q, p) w^\psi_\psi(q, p) \quad (15)$$

and inserting into (15) the definition of the Weyl quantization for $a \in \mathcal{S}(\mathbb{R}^{2d})$

$$(\hat{a} \psi)(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^{2d}} d\xi \; d_\xi \; a(\frac{1}{2} (x + y), \xi) e^{i \xi \cdot (x-y)} \psi(y),$$

one arrives at the formula

$$w^\psi_\psi(q, p) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^{2d}} d\xi \; e^{i \xi \cdot p} \; \psi^*(q + \varepsilon \xi/2) \psi(q - \varepsilon \xi/2) \quad (16)$$

7
for the Wigner function. Direct computation yields
\[
\| w^\psi_{\varepsilon} \|_{L^2(\mathbb{R}^{2d})} = \varepsilon^{-d} (2\pi)^{-d/2} \| \psi \|_{L^2(\mathbb{R}^d)}^2.
\]

Therefore, \( w^\psi_{\varepsilon} \in L^2(\mathbb{R}^{2d}) \) for all \( \varepsilon > 0 \), which explains the notion of Wigner function. Although \( w^\psi_{\varepsilon} \) is obviously real-valued, it attains also negative values in general. Hence, it does not define a probability distribution on phase space. However, it correctly produces quantum mechanical distributions via (15).

With this preparations we obtain the following corollary of Theorem 11, which says that the Wigner function of the solution of the Schrödinger equation (4) is approximately transported along the classical flow of (1) resp. (7).

**Corollary 2.** Let \( E_n \) be an isolated, non-degenerate Bloch band. Then for each finite time-interval \( I \subset \mathbb{R} \) there is a constant \( C < \infty \) such that for \( t \in I \), \( a \in C_{\text{per}} \) and for \( \psi_0 \in \Pi_n^e L^2(\mathbb{R}^d) \) one has
\[
\left| \left\langle \left(w^\psi_{\varepsilon} - w^\psi_0 \circ \Phi_{\varepsilon}^{-t} \right), a \right\rangle_{C', C} \right| \leq \varepsilon C d_C(a) \| \psi_0 \|^2
\]
and
\[
\left| \left\langle \left(w^\psi_{\varepsilon} - w^\psi_0 \circ \Phi_{\varepsilon}^{-t} \right), a \right\rangle_{C', C} \right| \leq \varepsilon^2 C d_C(a) \| \psi_0 \|^2.
\]

Here \( \psi_t = e^{-iHt/\varepsilon} \psi_0 \) is the solution of the Schrödinger equation (4).

**Remark.** When proving results for the transport of Wigner functions or Wigner measures it is common, e.g. [GMMP, MMP, BMP], to write down the transport equation for \( w_\varepsilon(t) := w^\psi_0 \circ \Phi_{\varepsilon}^{-t} \) instead of using the flow \( \Phi_{\varepsilon} \). Clearly our results can be reformulated in this way, cf. Corollary 3, but the resulting transport equation looks complicated compared to the simple dynamical system (1) governing its characteristics.

**Proof of Corollary 2.** The result is rather a reformulation of Theorem 11 than a real corollary. According to the Definition (15) and Theorem 11 one has
\[
\left\langle w^\psi_{\varepsilon}, a \right\rangle_{C', C} = \left\langle \psi_t, \tilde{a} \psi_0 \right\rangle_{L^2(\mathbb{R}^d)}
\]
\[
= \left\langle \psi_0, e^{iHt/\varepsilon} \tilde{a} e^{-iHt/\varepsilon} \psi_0 \right\rangle_{L^2(\mathbb{R}^d)}
\]
\[
= \left\langle \psi_0, \Pi_n^e e^{iHt/\varepsilon} \tilde{a} e^{-iHt/\varepsilon} \Pi_n^e \psi_0 \right\rangle_{L^2(\mathbb{R}^d)}
\]
\[
= \left\langle \psi_0, \Pi_n^e a \circ \Phi_{\varepsilon} \Pi_n^e \psi_0 \right\rangle_{L^2(\mathbb{R}^d)} + O(\varepsilon^2)
\]
\[
= \left\langle \psi_0, a \circ \Phi_{\varepsilon} \psi_0 \right\rangle_{L^2(\mathbb{R}^d)} + O(\varepsilon^2).
\]

Since the map \( C \ni a \mapsto a \circ \Phi_{\varepsilon} \in C \) is continuous, the duality relation (15) can be applied again and yields
\[
\left\langle \psi_0, a \circ \Phi_{\varepsilon} \psi_0 \right\rangle_{L^2(\mathbb{R}^d)} = \left\langle w^\psi_{\varepsilon}, a \circ \Phi_{\varepsilon}^{-t} \right\rangle_{C', C} = \left\langle w^\psi_0 \circ \Phi_{\varepsilon}^{-t}, a \right\rangle_{C', C}.
\]
\[
\square
\]
Since the functions $E_n, M_n$ and $\Omega_n$ appearing in the equations of motion (7) are all $\Gamma^*$ periodic, the natural phase space for the flow (7) is $R^d \times T^* \Gamma^*$ rather than $R^{2d}$. Here $T^d := R^d / \Gamma^*$ is the first Brillouin zone $M^*$ equipped with periodic boundary conditions. Hence one can fold the Wigner transform onto the first Brillouin zone and define

$$w_{\varepsilon}^{\psi}(r, k) = \sum_{\gamma^* \in \Gamma^*} w_{\psi}(r, k + \gamma^*) \quad \text{for} \quad (r, k) \in R^d \times T^d. \quad (17)$$

Then for periodic observables $a$ it follows that

$$\int_{R^d} dr \, dk \, a(r, k) \, w_{\psi}(r, k) = \sum_{\gamma^* \in \Gamma^*} \int_{R^d \times M^*} dr \, dk \, a(r, k + \gamma^*) \, w_{\psi}(r, k + \gamma^*)$$

$$= \sum_{\gamma^* \in \Gamma^*} \int_{R^d \times M^*} dr \, dk \, a(r, k) \, w_{\psi}(r, k + \gamma^*)$$

$$= \int_{R^d \times T^d} dr \, dk \, a(r, k) \, w_{\varepsilon}^{\psi}(r, k).$$

Thus the statement of Corollary 2 in terms of the reduced Wigner function becomes

$$\langle \psi_t, \hat{a} \psi_t \rangle_{L^2(R^d)} = \int_{R^d \times T^d} dr \, dk \, a(r, k) \left( w_{\psi_0}^{\psi} \circ \Phi^{-1}_{\varepsilon} \right) (r, k) + O(\varepsilon^2).$$

Note that the reduced Wigner function $w_{\varepsilon}^{\psi}$ coincides with the “band-Wigner function” of MMP and the “Wigner series” of BMP, both defined as

$$w_{\varepsilon}^{\psi}(r, k) = \frac{1}{|M^*|} \sum_{\gamma \in \Gamma} e^{i \gamma \cdot k} \psi(r + \varepsilon \gamma / 2) \psi^*(r - \varepsilon \gamma / 2).$$

This follows by a simple computation on the dense set $\psi \in S(R^d)$:

$$w_{\varepsilon}^{\psi}(r, k) = \sum_{\gamma^* \in \Gamma^*} w_{\varepsilon}^{\psi}(r, k + \gamma^*)$$

$$= \frac{1}{(2\pi)^d} \sum_{\gamma^* \in \Gamma^*} \int_{R^d} d\xi \, e^{i \xi \cdot \gamma^*} \psi(r + \varepsilon \xi / 2) \psi^*(r - \varepsilon \xi / 2)$$

$$= \frac{1}{|M^*|} \int_{R^d} d\xi \, \delta_{\Gamma}(\xi) \, e^{i \xi \cdot k} \psi(r + \varepsilon \xi / 2) \psi^*(r - \varepsilon \xi / 2)$$

$$= \frac{1}{|M^*|} \sum_{\gamma \in \Gamma} e^{i \gamma \cdot k} \psi(r + \varepsilon \gamma / 2) \psi^*(r - \varepsilon \gamma / 2),$$

where $\delta_{\Gamma}(\xi) = \sum_{\gamma \in \Gamma} \delta(\xi - \gamma)$. We used the Poisson formula

$$\frac{1}{(2\pi)^d} \sum_{\gamma^* \in \Gamma^*} e^{i \xi \cdot \gamma^*} = \frac{1}{|M^*|} \delta_{\Gamma}(\xi).$$
4 Classical transport of the Wigner measure

We now turn to the Wigner measure. Recall that the Wigner function $w_\psi(q,p)$ can be negative and, as a consequence, does not define a probability distribution on phase space. In the limit $\varepsilon \to 0$ however, $w_\psi$ weakly converges to a positive finite Radon measure $\mu_\psi \in M^+_b(\mathbb{R}^{2d})$ on phase space $\mathbb{R}^{2d}$, the Wigner measure of $\psi$. For surveys on Wigner measures see e.g. [LiPa, GMMP].

**Proposition 3.** Let $\{\varepsilon_j\} \to 0$ and $\{\psi_j\} \subset L^2(\mathbb{R}^d)$ be bounded, then the set $\{w_\psi^\varepsilon_j\} \subset C'$ is weak-* compact and every limit point $\mu \in C'$ defines a bounded positive Radon measure, called a Wigner measure of $\{\psi_j\} \subset L^2(\mathbb{R}^d)$.

**Proof.** The Calderon-Vaillancourt theorem (14) implies that $\{w_\psi^\varepsilon_j\} \subset C'$ is bounded. Hence, it is weak-* compact. By (15) and the semiclassical sharp Gårding inequality, e.g. Theorem 7.12 in [DiSj], it follows that for each $a \geq 0$ there is some $C < \infty$ such that

$$\langle w_\psi^\varepsilon_j, a \rangle_{C', C} \leq C \varepsilon \|\psi\|_2^2$$

for all $\psi \in L^2(\mathbb{R}^d)$. This implies the positivity of all limit points in $C'$, which therefore define measures.

Let $\mu \in C'$ be such a limit point with, after possible extraction of a subsequence, $w_\psi^\varepsilon_j \rightharpoonup \mu$. From (15) it follows that

$$\langle w_\psi^\varepsilon_j, 1 \rangle_{C', C} = \|\psi\|_{L^2(\mathbb{R}^d)}^2$$

and thus,

$$\mu(\mathbb{R}^{2d}) = \sup \{\mu(K) : K \subset \mathbb{R}^{2d} \text{ compact}\} \leq \langle \mu, 1 \rangle_{C', C} = \lim_{j \to \infty} \langle w_\psi^\varepsilon_j, 1 \rangle_{C', C} = \lim_{j \to \infty} \|\psi_j\|_{L^2(\mathbb{R}^d)}^2.$$

Hence, $\mu$ is bounded. \qed

However, not all limit points are physically sensible. For example, the bounded sequence $\psi_j(x) := \psi_0(x - j) \in L^2(\mathbb{R})$ has a limit point in $C'$, some Banach-limit type functional, but the corresponding measure is zero. More generally, there are many continuous linear functionals on $C$ which are zero on the (non dense) subset $C_0^\infty(\mathbb{R}^{2d})$.

**Definition.** A sequence $\{\psi_j\} \subset L^2(\mathbb{R}^d)$ remains localized in phase space (with respect to $\{\varepsilon_j\} \subset \mathbb{R}$), if it is compact at infinity, i.e.

$$\lim_{n \to \infty} \limsup_{j \to \infty} \int_{|x| \geq n} dx \, |\psi_j(x)|^2 = 0,$$

and $\varepsilon$-oscillatory, i.e.

$$\lim_{n \to \infty} \limsup_{j \to \infty} \frac{1}{\varepsilon_j} \int_{|p| \geq n} dp \, |\hat{\psi}_j(p/\varepsilon_j)|^2 = 0.$$
Proposition 4. Let $w_{\varepsilon_j}^{\psi_j} \xrightarrow{\kappa} \mu$ in $C'$ with $\{\psi_j\}_{j \in \mathbb{N}} \subset L^2(\mathbb{R}^d)$ bounded and localized in phase space, then $\mu$ has total mass

$$\mu(\mathbb{R}^{2d}) = \lim_{j \to \infty} \|\psi_j\|_{L^2(\mathbb{R}^d)}^2,$$  

and its marginals are given through the weak limits $\{w_{\varepsilon_j}^{\psi_j}\}$ of the quantum mechanical distributions, i.e. for all $a \in C^0_b(\mathbb{R}^d)$ one has

$$\int \mu(dq,dp) a(q) = \lim_{j \to \infty} \int dq |\psi_j(q)|^2 a(q),$$

$$\int \mu(dq,dp) a(p) = \lim_{j \to \infty} \varepsilon_j^{-d} \int dp |\tilde{\psi}_j(p/\varepsilon_j)|^2 a(p).$$

Proof. We start with the position marginal $\{w_{\varepsilon_j}^{\psi_j}\}$. Let $a \in C^0_b(\mathbb{R}^d)$ and let $\{a_n\}_{n \in \mathbb{N}} \subset C^\infty_0(\mathbb{R}^d)$ and $\{\chi_n\}_{n \in \mathbb{N}} \subset C^\infty_0(\mathbb{R}^d)$ satisfy $a_n(q) = a(q)$ and $\chi_n(p) = 1$ for $|q| \leq n$ resp. $|p| \leq n$. Then, by dominated convergence,

$$\int \mu(dq,dp) a(q) = \lim_{n \to \infty} \int \mu(dq,dp) a_n(q) \chi_n(p)$$

$$= \lim_{n \to \infty} \langle \mu, a_n \chi_n \rangle_{C',C} = \lim_{n \to \infty} \lim_{j \to \infty} \langle w_{\varepsilon_j}^{\psi_j}, a_n \chi_n \rangle_{C',C}$$

$$= \lim_{j \to \infty} \int dq |\psi_j(q)|^2 a(q) + R,$$

where

$$|R| \leq \lim_{n \to \infty} \lim_{j \to \infty} \langle w_{\varepsilon_j}^{\psi_j}, (a - a_n \chi_n) \rangle_{C',C}$$

$$\leq \lim_{n \to \infty} \lim_{j \to \infty} (\|\psi_j, (\tilde{a} - \tilde{a} \chi_n) \psi_j\| + \|\psi_j, (\tilde{a} \chi_n - \tilde{a} \chi_n) \psi_j\|)$$

$$= \lim_{n \to \infty} \lim_{j \to \infty} (\|\psi_j, (\tilde{a} - \tilde{a} \chi_n) \psi_j\| + \|\psi_j, (\tilde{a} \chi_n - \tilde{a} \chi_n) \psi_j\|)$$

$$\leq \lim_{n \to \infty} \lim_{j \to \infty} (\|\tilde{a} \psi_j\| \|1 - \chi_n\| \psi_j\| + \|a - a_n\| \psi_j\| \|\tilde{a} \psi_j\|)$$

$$= 0.$$  

For the last equality we used that $\{\psi_j\}$ is localized in phase space. In order to prove $\{w_{\varepsilon_j}^{\psi_j}\}$ also for $a \in C^0_b$ note that we just proved that the right hand side of (19) defines a measure. Hence, the result follows again by dominated convergence. The statements about the momentum marginal and the total mass follow analogously. \qed

We now turn to the propagation of Wigner measures. As remarked in the introduction, a popular approach to the semiclassical limit of (4) is to determine the resulting transport equation for the Wigner measure associated with an $\varepsilon$-dependent initial condition

Corollary 5. Let $E_n$ be an isolated, non-degenerate Bloch band. Let $\mu_0$ be the Wigner measure of a bounded sequence $\{\psi_{0,j}\}$ with $\psi_{0,j} \in \Pi^d \cap L^2(\mathbb{R}^d)$, i.e. $w_{\varepsilon_j}^{\psi_{0,j}} \xrightarrow{\kappa} \mu_0$ in $C'$.
Then the Wigner function $w_{\psi_t,j}^{\psi_{0,j}}$ of the time-evolved sequence

$$\psi_{t,j} := e^{-iH^t_j / \epsilon_j}\psi_{0,j}$$

has the weak-∗ limit $\mu_t \in \mathcal{C}_{\text{per}}'$ given through

$$\mu_t = \mu_0 \circ \Phi_0^{-t}. \quad (20)$$

In particular, $\mu_t$ is a positive bounded measure and solves the transport equation

$$\dot{\mu} + \nabla E_n(k - A(r)) \cdot \nabla \mu - \left( \nabla \phi(r) - \partial_t E_n(k - A(r)) \nabla A_l(r) \right) \cdot \nabla k \mu = 0$$

in the distributional sense.

Similar results were proved in [MMP, GMMP, BFPR] for the case of vanishing external potentials $A$ and $\phi$. For vanishing magnetic potential $A$ but nonzero electric potential $\phi$ they follow from the results in [HST] or [BMP].

**Proof of Corollary 5.** According to Corollary 2 we have for $a \in \mathcal{C}_{\text{per}}$ that

$$\left| \left\langle \left( w_{\psi_t,j}^{\psi_{0,j}} - w_{\psi_t,j}^{\psi_{0,j}} \circ \Phi_0^{-t} \right), a \right\rangle \right|_{\mathcal{C}_0', \mathcal{C}} \leq \epsilon_j C d_{\mathcal{C}}(a) \| \psi_{0,j} \|^2.$$

Taking the limit $j \to \infty$ on both sides yields the existence of the limit $\mu_t$ and at the same time (20). The transport equation for $\mu_t$ follows by taking a time-derivative in (20) and recalling that $\Phi_0^{-t}$ is the Hamiltonian flow of (2).

**Acknowledgements.** We are grateful to Caroline Lasser for helpful discussions on Wigner measures. This work was supported by the priority program “Analysis, Modeling and Simulation of Multiscale Problems” of the German Science Foundation (DFG).
