Abstract

We investigate the relation between the diagonal (\(\sigma_{xx}\)) and off-diagonal (\(\sigma_{xy}\)) components of the conductivity tensor in the quantum Hall system. We calculate the conductivity components for a short-range impurity potential using the linear response theory, employing an approximation that simply replaces the self-energy by a constant value \(-i\hbar/(2\tau)\) with \(\tau\) the scattering time. The approximation is equivalent to assuming that the broadening of a Landau level due to disorder is represented by a Lorentzian with the width \(\Gamma = \hbar/(2\tau)\). Analytic formulae are obtained for both \(\sigma_{xx}\) and \(\sigma_{xy}\) within the framework of this simple approximation at low temperatures. By examining the leading terms in \(\sigma_{xx}\) and \(\sigma_{xy}\), we find a proportional relation between \(d\sigma_{xy}/dB\) and \(B\sigma_{xx}^2\). The relation, after slight modification to account for the long-range nature of the impurity potential, is shown to be in quantitative agreement with experimental results obtained in the GaAs/AlGaAs two-dimensional electron system at the low magnetic field regime where spin splitting is negligibly small.

(Some figures in this article are in colour only in the electronic version)

1. Introduction

The experimental finding by Chang and Tsui [1] of the striking similarity between the longitudinal resistivity \(\rho_{xx}\) and the derivative of the Hall resistivity with respect to the electron density \(\rho_{xy}/dn_e\), in the quantum Hall regime has attracted considerable interest and has since been a subject of a number of experimental [2–8] and theoretical [9–11] studies. Using a low-carrier-density \((n_e \leq 1 \times 10^{-15} \text{ m}^{-2})\) high mobility \((\mu \geq 300 \text{ m}^2 \text{ V}^{-1} \text{ s}^{-1})\) two-dimensional electron system (2DES) in GaAs/AlGaAs, Stormer et al [4] showed that all features in \(\rho_{xx}\) (including overshooting flanks around quantum Hall states) are faithfully reproduced by the derivative of \(\rho_{xy}\) with respect to the magnetic field \(B\) in the form

\[
B \frac{d\rho_{xy}}{dB} \simeq \beta \rho_{xx},
\]

where \(\beta\) is a sample-dependent constant value (typically between 20 and 40). Note, as pointed out in [1], that the differentiation by \(B\) and that by \(n_e\) are basically equivalent to each other, \(-B(d/dB) = n_e(d/dn_e)\), if the relevant variable in the problem is the filling factor \(\nu = n_e\hbar/eB\) and not \(n_e\) or \(B\) separately.

The origin of the intriguing empirical relation equation (1) remains largely enigmatic. A possible explanation is given by Simon and Halperin [10], who ascribed the relation to...
the microscopic inhomogeneity in the electron density $n_e$ inevitably present in real 2DES samples. Noting that the macroscopic value of $\rho_{\text{xx}}$ measured in experiments is mainly determined by the fluctuation in the local Hall resistivity $\rho_{\text{xx}}(\vec{r})$ resulting from the inhomogeneity in $n_e$ rather than by the local longitudinal resistivity $\rho_{\text{xx}}$, their theory leads to equation (1) for not too low temperatures if disorder is taken into consideration on multiple length scales. In a recent experiment by Pan et al. [8] using an ultrahigh mobility ($\mu = 3100 \text{ m}^2 \text{ V}^{-1} \text{ s}^{-1}$) 2DES at an extremely low temperature (~6 mK), an experimentally measured value of $\rho_{\text{xx}}$ was interpreted [8, 11] as essentially reflecting the difference in $\rho_{\text{xx}}(\vec{r})$ between the voltage probes placed under slightly different (~0.5%) electron density $n_e$, and accordingly as virtually irrelevant to the local resistivity $\rho_{\text{xx}}(\vec{r})$. Note, however, that the van der Pauw geometry used in their study is not necessarily an ideal set-up for the measurement of the resistivity.

In the present paper, we explicitly calculate the diagonal ($\sigma_{\text{xx}}$) and the off-diagonal ($\sigma_{\text{xy}}$) components of the conductivity tensor in the quantum Hall system by employing the linear response theory. Although there already exist a number of sophisticated theories devoted to the calculation of the conductivity tensor in the quantum Hall system (see, e.g., [12–15]), they have not been applied, to the knowledge of the present authors, to the interpretation of the relation between the two components of the conductivity tensor exemplified by equation (1). We take the effect of disorder into account by simply assuming the Lorentzian broadening of the Landau levels with the width $\Gamma$ independent of $B$; this can readily be done by substituting a constant value $-i\Gamma$ for the self-energy in the Green’s function. Although this appears to be somewhat an oversimplified approximation, the Lorentzian with the $B$-independent width is suggested by a number of experiments to be a function that describes quite well the broadening of Landau levels due to disorder [16–19]. In contrast, the well-known self-consistent Born approximation [12] yields a semi-elliptical broadening, which is by far a less accurate representation of the experimentally observed Landau levels.

A great advantage of the simple approximation employed in the present study is that it allows us to deduce analytical formulae for both $\sigma_{\text{xx}}$ and $\sigma_{\text{xy}}$ for low enough temperatures $k_B T \ll \varepsilon_F$ with $\varepsilon_F$ the Fermi energy. The analytic formulae, in turn, provide us with a transparent way to examine the underlying relation between the two components. By picking out the most significant terms at high magnetic fields in the formulae, we find the relation

$$\frac{d\sigma_{\text{xy}}}{dB} \simeq \lambda B \sigma_{\text{xx}}^2,$$

with the coefficient $\lambda$ determined by scattering parameters and $\varepsilon_F$ (see equation (45) below for details). The relation is analogous to equation (1) but with a notable difference that $\sigma_{\text{xx}}$ enters the equation in squared form. Note that equation (1) can be rewritten as

$$B \frac{d\sigma_{\text{xy}}}{dB} \simeq \beta \sigma_{\text{xx}},$$

by using the approximate relations for not too small magnetic fields, $\rho_{\text{xy}} \approx 1/\sigma_{\text{xy}}$ and $\rho_{\text{xx}} \approx \sigma_{\text{xx}}/\sigma_{\text{xy}}^2$. In contrast to the previous study [10], we have not introduced inhomogeneity in $n_e$ in our calculation.

The relation between $\sigma_{\text{xx}}$ and $\sigma_{\text{xy}}$ found in the present study is compared with experimental results obtained in a GaAs/AlGaAs 2DES using the Hall bar geometry, a geometry well suited to the measurement of the resistivity. Care should be taken in the comparison, since our theoretical calculation is based on the short-range impurity potential, while the dominant scattering in a GaAs/AlGaAs 2DES is known to be of long-range. We find that equation (53) below obtained by modifying equation (2) to accommodate the long-range potential describes the experimental results remarkably well for the low magnetic field range where the spin splitting, the localization, the formation of edge states and the electron–electron interaction can be neglected.

This paper is organized as follows. In section 2, we introduce the Green’s function to be employed in the later calculations. Components of the conductivity tensor are calculated in section 3, which are shown in the appendix to approach the semiclassical formulae asymptotically for $B \to 0$. The relation between $\sigma_{\text{xx}}$ and $\sigma_{\text{xy}}$ is examined in section 4 and is compared with experimental results in section 5 after modification to account for the long-range nature of the impurity potential. The validity of our approximation and the magnetic field range for our approximation to be accurate are discussed in section 6, followed by concluding remarks in section 7.

### 2. Impurity scattering in the quantum Hall system

We consider a 2DES in a magnetic field perpendicular to the 2D plane. The Hamiltonian of the system is given by

$$H_{\text{QH}} = H_0 + V_{\text{imp}},$$

$$H_0 = \frac{1}{2m^*}(\vec{p} + e\vec{A})^2,$$

where $\vec{p}$ denotes the momentum operator, $-e$ is the charge of an electron, $\vec{A}$ is the vector potential of the magnetic field $(0, 0, B)$ and $V_{\text{imp}}$ represents the impurity potential. We neglect spins for simplicity. The term $H_0$ in the Hamiltonian gives the Landau levels. The eigenfunction of $H_0$ in the Landau gauge is given by

$$\phi_N(x, y) = \frac{1}{\sqrt{L}} e^{ikx} \chi_N(y - y_N),$$

where $L$ is the length of the system, $\chi_N$ denotes the eigenfunction of the harmonic oscillator in the $N$th Landau level whose energy is given by $E_N = \hbar \omega_c (N + 1/2)$ with $\omega_c = e|B|/m^*$ the cyclotron frequency, and $y_N = -k^2$ is the guiding center with $k = \sqrt{\hbar/|e| |B|}$ the magnetic length.

We consider a short-range potential of the form

$$V_{\text{imp}}(\vec{r}) = \sum_i V_i \delta(\vec{r} - \vec{r}_i).$$

Owing to the impurity potential, Landau levels acquire width, which are otherwise delta functions placed at $\varepsilon = E_N (N = 0, 1, 2, \ldots)$. The resulting density of states (DOS), or the
lineshape of the impurity-broadened Landau levels, has been calculated for various types of impurity potential. For a white-noise potential (impurities with constant strength \( V_i \) distributed at random positions \( \vec{\mathbf{r}}_i \)), the broadening was shown to be well described by a Gaussian lineshape \[20–22\]. Calculations were also done assuming a distribution \( P(V_i) \) in the strength of the impurity scattering \( V_i \) \[21–27\]. Brezin et al \[21\] and Benedict et al \[25\] showed that a Lorentzian distribution of \( P(V_i) \) results in DOS described by a Lorentzian lineshape. Lorentzian broadening of the Landau levels is consistent with experiments on the tunneling into a 2DES \[16, 19\] or measurement of the magnetization in a 2DES \[17, 18\].

In the present paper, we start by assuming the Lorentzian DOS

\[
D(\epsilon) = \frac{1}{2\pi \ell^2} \sum_{N=N_0}^{\infty} \frac{1}{\pi} \frac{1}{(\epsilon - E_N)^2 + \Gamma^2},
\]

(8)

As will be shown, this simple approximation allows us to deduce analytic formulae of the conductivity tensor, which proves to be essential for the later analysis of the relation between the components of the conductivity tensor.

The simple DOS equation (8) implies analogous simplicity in the electron Green’s function. For a sufficiently short-ranged impurity potential, the Green’s function can be written in the diagonalized form as

\[
G_N(\epsilon) \delta_{N,N'} \delta_{k,k'} = \left( N, k \right) \frac{1}{\epsilon - \Sigma_{QH}|N', k'}
\]

\[
= \frac{\delta_{N,N'} \delta_{k,k'}}{\epsilon - E_N - \Sigma_N(\epsilon)},
\]

(9)

where \( |N, k \rangle \) represents the eigenstate of the unperturbed Hamiltonian given by equation (6) and \( \Sigma_N(\epsilon) \) denotes the self-energy resulting from \( V_{imp} \). The DOS is related to the imaginary part of the electron Green’s function (9) by

\[
D(\epsilon) = -\frac{1}{2\pi \ell^2} \sum_N \rho_N(\epsilon),
\]

(10)

with \( \rho_N(\epsilon) \) introduced as

\[
\rho_N(\epsilon) = \frac{1}{\pi} \text{Im} \ G_N(\epsilon + i0).
\]

(11)

It is easy to see that equation (10) reproduces equation (8) if the self-energy \( \Sigma_N(\epsilon) \) in equation (9) is replaced by a constant value \(-i\Gamma = -i\hbar/(2\tau)\), yielding

\[
G_N(\epsilon + i0) = \frac{1}{\epsilon - E_N + i\Gamma}.
\]

(12)

We exploit the simple Green’s function equation (12) in the following calculations.

3. Conductivity tensor

We introduce the particle-current operator \( \vec{j} \) of the form

\[
\vec{j} = \frac{1}{m^*}(\vec{p} + e\vec{A}).
\]

(13)

The conductivity tensor \( \sigma_{\alpha\beta} \) (with \( \alpha \) and \( \beta \) representing either of \( x \) or \( y \)) of the 2DES is given by the Kubo formula

\[
\sigma_{\alpha\beta}(\omega) = \text{Re} \left[ \frac{1}{i\omega} \langle K_{\alpha\beta}(\omega + i0) - K_{\alpha\beta}(0) \rangle \right],
\]

(14)

where \( K_{\alpha\beta} \) represents the thermal Green’s function corresponding to the current–current correlation function:

\[
K_{\alpha\beta}(i\omega_n) = -\frac{e^2}{L^2} \int_0^{\hbar/\ell} \frac{d\tau}{\hbar} \langle \sigma_{\alpha\beta}(\tau) \rangle,
\]

(15)

with \( L \) the system size, \( \tau \) the chronological operator and \( \omega_n = 2n\pi\ell\hbar/T \) for an integer \( n \). The bracket \( \langle \cdot \cdot \cdot \rangle \) here denotes the ensemble average. In the calculation of the conductivity tensor (14), we consider only the loop diagram shown in figure 1 and neglect the correction from the current vertex part.

The correlation function \( K_{\alpha\beta} \) is then written as

\[
K_{\alpha\beta}(i\omega_n) = -\frac{k_B T e^2}{L^2} \sum_{N,k,N',k'} \langle N, k | j_{\alpha}(\tau) j_{\beta}(\tau) | N', k' \rangle,
\]

\[
= \langle N, k | j_{\alpha} | N', k' \rangle \langle N', k' | j_{\beta} | N \rangle,
\]

(16)

where the electron Green’s function \( G_N \) is given by equation (12) and the matrix elements of the particle current are

\[
\langle N, k | j_{\alpha} | N', k' \rangle = \left( N + 1 \right) \frac{\delta_{N',N+1}}{2} \delta_{k,k'},
\]

\[
\langle N, k | j_{\alpha} | N', k' \rangle = \left( \frac{1}{m}\hbar \right) \sqrt{N + 1} \delta_{N',N+1} + \left( \frac{1}{m}\hbar \right) \sqrt{N} \delta_{N',N-1} \delta_{k,k'}.
\]

(17)

Performing analytical continuation of \( i\omega_n \) to \( \omega \) and taking the limit \( \omega \rightarrow 0 + i0 \), we obtain the dc parts of the diagonal and off-diagonal components in the conductivity tensor in the forms

\[
\sigma_{xx}(T, \varepsilon_F) = \frac{e^2}{2\hbar} (\hbar\omega_F)^2 \int_{-\infty}^{\infty} d\varepsilon \left( -\frac{\partial f(\varepsilon)}{\partial \varepsilon} \right)
\]

\[
\times \sum_{N=0}^{\infty} \langle N + 1 \rangle \rho_N(\varepsilon) \rho_{N+1}(\varepsilon),
\]

(18)

\[
\sigma_{xy}(T, \varepsilon_F) = -\frac{e^2}{2\hbar} (\hbar\omega_F)^2 \int_{-\infty}^{\infty} d\varepsilon f(\varepsilon)(N+1)
\]

\[
\times \left( \rho_N(\varepsilon) \frac{\partial G_{N+1}(\varepsilon + i0)}{\partial \varepsilon} - \rho_{N+1}(\varepsilon) \frac{\partial G_N(\varepsilon + i0)}{\partial \varepsilon} \right),
\]

(19)
where $f(\varepsilon) = 1/\left[\text{exp}(\varepsilon - \varepsilon_F)/(k_B T)\right] + 1$ is the Fermi distribution function. Equations (18) and (19) are basically equivalent to equations (50) and (51) in [28] by Jonson and Girvin, except that the self-energy in the Green’s function is replaced by a constant value in our case.

We can calculate the components of the conductivity tensor equations (18) and (19) further using the electron Green's function (12). We first examine the diagonal component $\sigma_{xx}$. For $k_B T \ll \varepsilon_F$, we can approximate the derivative of the Fermi function by the delta function $-\partial f(\varepsilon)/\partial \varepsilon \simeq \delta(\varepsilon - \varepsilon_F)$. Thus equation (18) becomes

$$\sigma_{xx}(\varepsilon_F) \simeq \frac{e^2}{2\hbar}(\varepsilon_F)^2 \sum_{N=0}^{\infty} (N+1) \rho_N(\varepsilon_F) \rho_{N+1}(\varepsilon_F).$$

(Introducing dimensionless parameters)

$$X_F = \frac{\varepsilon_F}{\hbar \omega_c} - \frac{1}{2},$$

and

$$\gamma = \frac{\Gamma}{\hbar \omega_c},$$

we can rewrite equation (20) as

$$\sigma_{xx}(\varepsilon_F) = \frac{e^2}{2\pi^2 \hbar} \left( 1 + 4\gamma^2 \right) \sum_{N=0}^{\infty} \left( X_F - N \right)^2 + \gamma^2.$$  

To evaluate the summation over $N$ in equation (23), we use the Poisson sum formula

$$\sum_{N=-\infty}^{\infty} N - X_F \mp iy = \pm 2\pi i \sum_{N=-\infty}^{\infty} \theta(\mp y) e^{-i2\pi N x - 2\pi \left|\mp y\right|},$$

where $\theta(\xi)$ is the unit step function. Using equation (24), we derive from equation (23)

$$\sigma_{xx}(\varepsilon_F) = \frac{e^2}{\hbar} \frac{2\gamma}{1 + 4\gamma^2} (X_F + 1/2) \sinh(2\pi \gamma) - \cos(2\pi \gamma X_F)$$

$$= \frac{e^2}{\hbar} \frac{2\gamma}{1 + 4\gamma^2} (X_F + 1/2) \sinh(2\pi \gamma) - \cos(2\pi \gamma X_F)$$

where we approximated $\sum_{N=0}^{\infty} \rightarrow \sum_{N=-\infty}^{\infty}$ by noting that terms with $N < 0$ are negligibly small at $\varepsilon_F$ in the typical situations $\varepsilon_F \gg \Gamma$. Equation (25) bears the same form as equation (2.11) in [12] by Ando if we replace our $X_F$ and $\gamma$ with $X'/\hbar \omega_c$ and $X''/\hbar \omega_c$, respectively. In the second equality in equation (25), we introduced the notation $\sigma_{ab}$ for the conductivity tensor normalized by $\hbar/e^2$.

Next we examine the off-diagonal component $\sigma_{xy}$ of the conductivity tensor. Introducing a variable of integration

$$X = \frac{\varepsilon}{\hbar \omega_c} - \frac{1}{2},$$

and performing the integration by parts, we rewrite equation (19) as

$$\sigma_{xy}(T, \varepsilon_F) = -\frac{e^2}{2\pi^2 \hbar} \sum_{N=0}^{\infty} (N+1)$$

$$\times \int_{-\infty}^{\infty} dX \left( -\frac{\partial f(\hbar \omega_c (X + 1/2))}{\partial X} \right) L_N(X),$$

with

$$L_N(X) = (\hbar \omega_c)^2 \int_{-\infty}^{\infty} \left[ \rho_N(\hbar \omega_c (X' + 1/2) + i0) \times \frac{\partial G_{N+1}(\hbar \omega_c (X' + 1/2) + i0)}{\partial X'} - \rho_{N+1}(\hbar \omega_c (X' + 1/2)) \times \frac{\partial G_N(\hbar \omega_c (X' + 1/2) + i0)}{\partial X'} \right] dX'.$$

For $k_B T \ll \varepsilon_F$, we obtain

$$\sigma_{xy}(\varepsilon_F) = -\frac{e^2}{\hbar} \sum_{N=0}^{\infty} (N+1) L_N(X_F).$$

Using equation (12) and performing the integration $L(X)$ in equation (28) up to $X_F$, we obtain

$$\sigma_{xy}(\varepsilon_F) = -\frac{e^2}{2\pi^2 \hbar} \left\{ \frac{2\gamma^3}{1 + 4\gamma^2} \sum_{N=0}^{\infty} \left[ \frac{1}{2\gamma^2} (X_F - N)^2 + \gamma^2 \right] \times \frac{2N + 1}{(X_F - N)^2 + \gamma^2} \right\} \left[ \arctan \left( \frac{X_F - N}{\gamma} \right) + \frac{\pi}{2} \right],$$

where we used equation (24), employing the approximation $\sum_{N=0}^{\infty} \rightarrow \sum_{N=-\infty}^{\infty}$ as before. Along the same lines, we can accurately approximate the last term on the rhs of equation (30) by

$$-\frac{e^2}{\hbar} \sum_{N=-\infty}^{\infty} \int_0^{X_F} \frac{1}{\pi} \frac{1}{(X - N)^2 + \gamma^2} dX + \frac{1}{2}$$

$$= -\frac{e^2}{\hbar} \left[ \sum_{N=-\infty}^{\infty} \int_0^{X_F} \frac{1}{\pi} \frac{1}{(X - N)^2 + \gamma^2} dX + \frac{1}{2} \right]$$

with $\text{Int}(\xi)$ representing the integer part of $\xi$. We finally arrive at

$$\sigma_{xy}(\varepsilon_F) = -\frac{e^2}{\hbar} \left[ \frac{1}{\cos(2\pi \gamma X_F) - \cos(2\pi \gamma X_F)} \times \left[ \frac{4\gamma^2 (X_F + 1/2)}{1 + 4\gamma^2} \sinh(2\pi \gamma) - \gamma \sin(2\pi \gamma X_F) \right] \right].$$
be typical values in a GaAs/AlGaAs 2DES: $m^* = 0.067m_0$ with $m_0$ the bare electron mass, $\varepsilon_F = 7.5$ meV and $\Gamma = h/(2\gamma) = 0.12$ meV. The traces basically reproduce well-known behavior of a 2DES in the magnetic field: the staircase with plateaus at integer multiples of $e^2/h$ for $\sigma_{xy}$ and peaks at inter-plateau transition for $\sigma_{xx}$. The non-monotonic $1/B$ dependence observed in $\sigma_{xx}$ for $B < 1$ T (the depression in $-\sigma_{xx}$ that occurs in step with the peak in $\sigma_{xy}$) is usually not seen in the experimental traces for a high mobility GaAs/AlGaAs 2DES, but can be seen in early experiments on Si-MOSFET [29] and is likely to be related to the short-range nature of the impurity potential. (See figure 4 below for a comparison with the result in the long-range potential.)

For brevity and for convenience in later use, we rewrite $\tilde{\sigma}_{xx}$ and $\tilde{\sigma}_{xy}$ in the concise formulae

$$\tilde{\sigma}_{xx}(X_F, \gamma) = \frac{2\gamma}{1 + 4\gamma^2} (X_F + \frac{1}{2}) \text{Fsinh}(X_F, \gamma)$$

$$\tilde{\sigma}_{xy}(X_F, \gamma) = -\text{Fsinh}(X_F, \gamma) - \gamma \text{Fsin}(X_F, \gamma)$$

$$+ \frac{4\gamma^2}{1 + 4\gamma^2} (X_F + \frac{1}{2}) \text{Fsinh}(X_F, \gamma),$$

where we introduced the notations $\text{Fsin}(X_F, \gamma)$, $\text{Fsinh}(X_F, \gamma)$ and $\text{IFsinh}(X_F, \gamma)$ defined as

$$\text{Fsin}(X_F, \gamma) = \frac{\sin(2\pi X_F)}{\cosh(2\pi X_F) - \cos(2\pi X_F)},$$

$$\text{Fsinh}(X_F, \gamma) = \frac{\sin(2\pi \gamma)}{\cosh(2\pi \gamma) - \cos(2\pi X_F)},$$

$$\text{IFsinh}(X_F, \gamma) = \int_{-\frac{1}{2}}^{X_F} dX \text{Fsin}(X, \gamma)$$

$$= \frac{1}{\pi} \arctan(\coth(\pi \gamma) \tan(\pi X_F)) + \text{Int}(X_F + \frac{1}{2}) + \frac{1}{2}.$$  

Although it appears, at first glance, that the stepwise behavior of $\sigma_{xy}$ is reflecting only the first term in equation (36), the second term is also playing its own share of roles by extending the width of the plateau and thus making the slope of the inter-plateau region much steeper than it would be were it not for the term. The steepness of the slope is of paramount importance in our theory that attempts to explain the behavior of $d\sigma_{xy}/dB$.

We note in passing that the DOS given by equation (8) can also be rewritten, following the same procedure as in the derivation of equation (35), as

$$D(\varepsilon) = D_0 \text{Fsinh}(X, \gamma),$$

where $D_0 = m^*/(2\pi h^2)$ represents the DOS of a 2DES in the absence of the magnetic field and $X = \varepsilon/(h\omega_c) - 1/2$ as defined earlier. Accordingly, the cumulative number of states $N(\varepsilon)$ below $\varepsilon$ is

$$N(\varepsilon) = \int_0^\varepsilon \frac{1}{2\pi} \text{IFsinh}(X, \gamma).$$

We will show in the appendix that equations (35) and (36) tend to the well-known semiclassical formula for $B \to 0$.

4. The relation between diagonal and off-diagonal conductivities at high magnetic fields

We now move on to the main topic of the present paper, the relation between $\tilde{\sigma}_{xx}$ and $\tilde{\sigma}_{xy}$ at high magnetic fields. Since both $X_F$ and $\gamma$ are functions of $B$, the derivative of the off-diagonal component $\tilde{\sigma}_{xy}$ with respect to $B$ is written as

$$\frac{d\tilde{\sigma}_{xy}(X_F, \gamma)}{dB} = \frac{d\tilde{\sigma}_{xy}(X_F, \gamma)}{dX_F} \frac{dX_F}{dB} + \frac{d\tilde{\sigma}_{xy}(X_F, \gamma)}{d\gamma} \frac{d\gamma}{dB}$$

$$= -\frac{1}{B} \left[ \left( X_F + \frac{1}{2} \right) \frac{\partial \tilde{\sigma}_{xy}(X_F, \gamma)}{\partial X_F} + \gamma \frac{\partial \tilde{\sigma}_{xy}(X_F, \gamma)}{\partial \gamma} \right].$$

Differentiation by $X_F$ and $\gamma$ can be analytically done on equation (36) and we obtain

$$\frac{d\tilde{\sigma}_{xy}(X_F, \gamma)}{dB} = \left( X_F + \frac{1}{2} \right) \frac{1 - 4\gamma^2}{(1 + 4\gamma^2)^2}$$

$$- \frac{1 + 8\gamma^2}{1 + 4\gamma^2} 2\pi \gamma \coth(2\pi \gamma) \text{Fsinh}(X_F, \gamma)$$

$$+ \left( X_F + \frac{1}{2} \right) \frac{1 + 8\gamma^2}{1 + 4\gamma^2} 2\pi \gamma \text{Fsinh}^2(X_F, \gamma)$$

$$- \left[ 1 - \frac{4}{1 + 4\gamma^2} \right] \left( X_F + \frac{1}{2} \right)^2 \times 2\pi \gamma^2 \text{Fsin}(X_F, \gamma) \text{Fsin}(X_F, \gamma),$$

or, with the aid of equation (35),

$$\frac{d\tilde{\sigma}_{xy}(X_F, \gamma)}{dB} = \frac{1}{2\gamma} \left[ 1 - \frac{4\gamma^2}{1 + 4\gamma^2} - 2\pi \gamma (1 + 8\gamma^2) \coth(2\pi \gamma) \right]$$

$$\times \tilde{\sigma}_{xx}(X_F, \gamma) + \frac{\pi}{2\gamma} \left( 1 + 8\gamma^2 \right)(1 + 4\gamma^2) \frac{\partial^2 \tilde{\sigma}_{xy}(X_F, \gamma)}{\partial X_F^2}.$$
In this section, we make an attempt to compare the relation between \( \tilde{\sigma}_{xx} \) and \( \tilde{\sigma}_{xy} \) deduced in section 4 to the experimental results obtained in a GaAs/AlGaAs 2DES. It is well known that the main source of scattering in a GaAs/AlGaAs 2DES is the ionized donors. The donors are set back from the 2DES account for the long-range potential. The horizontal axis is the inverse magnetic field.

Figure 4. The diagonal (equation (49)) and the off-diagonal (equation (50)) components of the conductivity tensor modified to account for the long-range potential. The horizontal axis is the inverse magnetic field.

and \( \tilde{\sigma}_{xx} \sim 0 \) away from the sharp peaks (see also figure 2). From equations (43) and (44), and noting that \( \sin(2\pi X_F) \sim 0 \) at \( X_F \sim N \), we find that the second term in equation (43) makes the dominant contribution, leading to our final result:

\[
\frac{d\tilde{\sigma}_{xy}(X_F, \gamma)}{dB} \approx \frac{\pi \mu h\hbar}{\epsilon_F} \tilde{\sigma}_{xx}^2(X_F, \gamma),
\]

or \( \lambda = (\hbar/e^2)\pi \hbar\mu(m^*\epsilon_F)^{-1} \) in equation (2). Here we made use of the mobility \( \mu = e\tau/m^* = e\hbar/(2m^*\Gamma) \). Plots of \( d\tilde{\sigma}_{xy}/dB \) calculated using equation (41) (solid red line) and \( \pi \mu(h\hbar\epsilon_F/\epsilon_F)\tilde{\sigma}_{xx}^2 \) with \( \tilde{\sigma}_{xx} \) computed by equation (35) (dashed green line) shown in figure 3 attest to the validity of equation (45) for \( B \geq 1 \) T. The deviation seen at lower magnetic fields is attributable to higher-order terms in \( \gamma \) neglected in equation (45). In figure 3, we used the same parameter values as in figure 2.

It is interesting to point out that we obtain the relation \( d\sigma_{xy}/dB \propto \sigma_{xx} \) instead of equation (45) if we keep only the first term in equation (36):

\[
\frac{d\tilde{\sigma}_{xy}(X_F, \gamma)}{dB} = \frac{1}{B} \left( X_F + \frac{1}{2} \right) F\sinh(X_F, \gamma) - \gamma F\sin(X_F, \gamma) \approx \mu \tilde{\sigma}_{xx},
\]

which is not legitimate as discussed below equation (37) in section 3. In fact, the peaks calculated by equation (46) exhibit much larger width and smaller (roughly half) height compared with those calculated by equation (41), as displayed in figure 3.

5. Comparison with experimental results

5.1. Modification for a long-range potential

In this section, we make an attempt to compare the relation between \( \tilde{\sigma}_{xx} \) and \( \tilde{\sigma}_{xy} \) deduced in section 4 to the experimental results obtained in a GaAs/AlGaAs 2DES. It is well known that the main source of scattering in a GaAs/AlGaAs 2DES is the ionized donors. The donors are set back from the 2DES...
plane by a spacer layer with the thickness typically a few tens of nanometers. Therefore, the scattering in a GaAs/AlGaAs 2DES should be described by a long-range impurity potential. Since a short-range potential is assumed in our theory, slight modification is necessary to implement the comparison. This is done by following the prescription given in [30].

First we observe that the off-diagonal component equation (36) can be rewritten in the form presented in [14], \( \sigma_{xy} = -\gamma [\partial N(\epsilon_F)/\partial B] - \omega_k \tau \sigma_{xx} \), which in the normalized form is

\[
\tilde{\sigma}_{xy} = -\frac{\hbar}{e} \frac{\partial N(\epsilon_F)}{\partial B} - \frac{1}{2\gamma} \tilde{\sigma}_{xx}.
\]

The equivalence of equation (47) to (36) can readily be verified by performing the differentiation by \( B \) on \( N(\epsilon_F) \) given by equation (39):

\[
\frac{\hbar}{e} \frac{\partial N(\epsilon_F)}{\partial B} = \text{I} \text{f} \text{s} \text{i} \text{n}h(X_F, \gamma) + \gamma F \sin(X_F, \gamma)
\]

\[
- (X_F + \frac{1}{2}) F \sinh(X_F, \gamma).
\]

In a long-range potential, it is important to recall that the scattering is characterized by two distinct scattering times, namely the quantum scattering time \( \tau_q = \hbar/(2\Gamma) \) that describes the impurity broadening of the Landau levels and the momentum relaxation time \( \tau_m = \sigma_{xx}^m/(\hbar e^2) \), related to the conductivity at \( B = 0 \). The latter time is typically 10 times larger than the former in a GaAs/AlGaAs 2DES, while the relaxation times are simply \( \tau_q = \tau_m = \tau \) for short-range scatterers. Coleridge et al [30] suggested an appropriate way of replacing \( \tau \) by either \( \tau_q \) or \( \tau_m \), with which the resultant \( \sigma_{xx} \) and \( \sigma_{xy} \) describe the conductivities under the long-range potential quite well. The method, in our notation, is to replace \( \gamma \) only in the prefactor of equation (35) by \( \gamma_m = 1/(2\omega_k \tau_m) \), leaving \( \gamma = \gamma_q = \Gamma/(\hbar \omega_k) = 1/(2\omega_k \tau_q) \) in \( \text{s} \text{i} \text{n}h(X, \gamma) \) intact:

\[
\tilde{\sigma}_{xx}^{\text{LR}} (X_F, \gamma_q, \gamma_m) = \frac{2\gamma_m}{1 + 4\gamma_m^2} \left[ X_F + \frac{1}{2} \right] \text{s} \text{i} \text{n}h(X_F, \gamma_q).
\]

The Hall conductivity is obtained by substituting \( \gamma_m \) and \( \tilde{\sigma}_{xx}^{\text{LR}} \) into the second term of equation (47) as

\[
\tilde{\sigma}_{xy}^{\text{LR}} (X_F, \gamma_q, \gamma_m) = -\frac{\hbar}{e} \frac{\partial N(\epsilon_F)}{\partial B} \bigg|_{\gamma = \gamma_q} - \frac{1}{2\gamma_m} \tilde{\sigma}_{xx}^{\text{LR}}
\]

\[= -\text{I} \text{f} \text{s} \text{i} \text{n}h(X_F, \gamma_q) - \gamma_q F \sin(X_F, \gamma_q) + 2\gamma_m \tilde{\sigma}_{xx}^{\text{LR}}. \tag{50}\]

With these substitutions, the derivative of \( \tilde{\sigma}_{xy}^{\text{LR}} \) by \( B \) is

\[
\frac{d\tilde{\sigma}_{xy}^{\text{LR}} (X_F, \gamma_q, \gamma_m)}{dB} = \frac{d\tilde{\sigma}_{xy}}{dB} + \frac{d\tilde{\sigma}_{xx}^{\text{LR}} (X_F, \gamma_q, \gamma_m)}{dB} \tag{51}\]

with

\[
\eta_1 (X_F, \gamma_q) = \frac{1}{B} \left[ \left( X_F + \frac{1}{2} \right) \text{s} \text{i} \text{n}h(X_F, \gamma_q) - \gamma_q F \sin(X_F, \gamma_q) \right],
\]

\[
\eta_2 (X_F, \gamma_q) = \frac{1}{B} \left\{ \left( X_F + \frac{1}{2} \right) 2\gamma_m F \sinh(X_F, \gamma_q) \right. \times [\text{s} \text{i} \text{n}h(X_F, \gamma_q) - \coth(2\gamma_q)] + \gamma_q F \sinh(X_F, \gamma_q) \right. \]

\[-2\gamma_m^2 F \sinh(X_F, \gamma_q) F \sinh(X_F, \gamma_q) \bigg\}.
\]

Figure 5. The plots of \( d\tilde{\sigma}_{xy}^{\text{LR}}/dB \) without approximation, equation (51) (thin solid red line), and \( d\tilde{\sigma}_{xy}^{\text{LR}}/dB \) approximated by equation (52) with \( \tilde{\sigma}_{xx}^{\text{LR}} \) calculated by equation (49) (thick dashed green line).

and

\[
\eta_3 (X_F, \gamma_q, \gamma_m) = \frac{2\gamma_m}{B} \tilde{\sigma}_{xx}^{\text{LR}} (X_F, \gamma_q, \gamma_m) \times \left\{ 2\pi \gamma_q \text{coth}(2\gamma_q) + 1 + \frac{2}{1 + 4\gamma_m^2} - 2\pi \right\} \times \left\{ (X_F + \frac{1}{2}) \text{s} \text{i} \text{n}h(X_F, \gamma_q) + \gamma_q F \sinh(X_F, \gamma_q) \right\},
\]

where the terms \( \eta_1 \), \( \eta_2 \) and \( \eta_3 \) are derived from the first, the second and the third term in equation (50), respectively. Accordingly, the dominant term at high magnetic field changes from equation (45) to

\[
\frac{d\tilde{\sigma}_{xy}^{\text{LR}} (X_F, \gamma_q, \gamma_m)}{dB} \simeq \frac{\pi}{\mu_m} \frac{\hbar \omega_k}{\gamma_m} \left[ \tilde{\sigma}_{xx}^{\text{LR}} (X_F, \gamma_q, \gamma_m) \right]^2, \tag{52}\]

(\( \lambda = (\hbar/e^2)\pi \hbar e (\mu_m^2/\mu_q) (m^* \gamma)^{-1} \) in equation (2)), where \( \mu_m = e \tau_m/m^* \) and \( \mu_m = e \tau_m/m^* \) are mobilities corresponding to \( \tau_q \) and \( \tau_m \), respectively.

In figure 4, we show the longitudinal and the Hall conductivities calculated by equations (49) and (50) with parameters \( \gamma_F = 7.5 \text{ meV}, \mu_q = 7.1 \text{ m}^2 \text{ V}^{-1} \text{ s}^{-1} \) (corresponding to \( \Gamma = 0.12 \text{ meV} \)) and \( \mu_m = 78 \text{ m}^2 \text{ V}^{-1} \text{ s}^{-1} \). The parameters are taken from our experiment to be presented below. The diagonal component \( \sigma_{xx} \) has become much smaller than in figure 2 (note the ten times magnification in figure 4), in accordance with experiments in a GaAs/AlGaAs 2DES. Note that the non-monotonic behavior of \( \sigma_{xx} \) observed in figure 2 has vanished in figure 4. The high accuracy of the approximation given by equation (52) at high enough magnetic fields (\( B \gtrsim 1 \text{ T} \)) is demonstrated in figure 5.

Although equation (52) as well as equation (45) is intended for use in high magnetic fields, stringent comparison with experimental results is possible only in a rather low magnetic field range (\( B \lesssim 0.5 \text{ T} \)) for a couple of reasons to be discussed in section 6. Above all, we neglected the spin of the electrons altogether in the theory. In principle, the spin can be included in the theory by adding \( \sigma_{xx} \mu_B B \) to \( E_N \) with \( \sigma = \pm 1/2 \) representing the spin and \( \mu_B \) the
Bohr magneton. Difficulty arises, however, because of the dependence of the $g$ factor on the magnetic field owing to the exchange interaction [31]: the $g$ factor experiences strong enhancement at the magnetic field where the Fermi energy lies between the Zeeman gap (exchange enhancement), which defies simple analytical treatment. If we limit ourselves to $B \lesssim 0.5$ T, spin splitting can be completely neglected because of the small (bare) $g$ factor $g = -0.44$ in GaAs. In this low magnetic field range, the approximation in equation (52) that retains only the leading term in $γ$ turns out to be insufficient, as demonstrated in figure 6. The approximation is improved by keeping the terms deriving from the first two terms on the rhs of equation (50), $η_1$ and $η_2$, except for the term including $\text{Fsin}(X_F, γ)$ (the third term $η_3$ can safely be neglected since $γ_m \ll γ_q$):

$$\frac{d\tilde{σ}_{xy}^{LR}(X_F, γ_q, γ_m)}{dB} \approx \frac{\pi \mu_m^2 \hbar \omega_{\text{F}}}{\mu_q^2 \gamma} \frac{\tilde{σ}_{xx}^{LR}(X_F, γ_q, γ_m)^2}{(\tilde{σ}_{xx}^{LR}(X_F, γ_q, γ_m))^2} + \mu_m \left[ 1 - \frac{\pi \mu_q^2 B}{\mu_q^2 B} \right] \frac{\tilde{σ}_{xx}^{LR}(X_F, γ_q, γ_m)}{(\tilde{σ}_{xx}^{LR}(X_F, γ_q, γ_m))^2}.$$ (53)

In figure 6, we plot $d\tilde{σ}_{xy}^{LR}(X_F, γ)/dB$ without approximation, equation (51), along with approximated traces, equations (52) and (53), calculated using $\tilde{σ}_{xx}^{LR}(X_F, γ)$ in equation (49). Deviation of equation (52) from the exact result becomes evident below $0.5$ T, while equation (53) reproduces the trace almost indistinguishably from that of the exact calculation in the magnetic field range shown in figure 6.

5.2. Relation between experimentally observed longitudinal and Hall conductivities

Let us now turn to our experimental data. We prepared a GaAs/AlGaAs 2DES sample with $μ_m = 77 \text{ m}^2 \text{ V}^{-1} \text{ s}^{-1}$ and $n_c = 2.1 \times 10^{15} \text{ m}^{-2}$, hence $\varepsilon_F = 7.5 \text{ meV}$, shaped in a Hall bar geometry by photolithography. The quantum mobility $μ_q = 7.1 \text{ m}^2 \text{ V}^{-1} \text{ s}^{-1}$ was determined from the damping of the amplitudes $Δρ_{\text{Shub}}$ of the Shubnikov–de Haas (SDH) oscillation at low magnetic fields, $Δρ_{\text{Shub}}(B)/ρ_0 = C \exp\left[-π/(μ_q B)\right]$ with $ρ_0$ the resistivity at $B = 0$ [32]. It was pointed out in [32] that the prefactor $C$ equals 4 in a homogeneous 2DES and the deviation from the value is attributable to the inhomogeneity. We have verified that the SDH amplitudes in our sample were described by the above equation with $C = 4$ reasonably well, confirming that inhomogeneity is minimal in our sample. (Note, however, that small inhomogeneity is inevitably present in a 2DES grown by molecular beam epitaxy, as will be discussed below.) Measurements were done in a dilution refrigerator equipped with a superconducting magnet at the base temperature ($\sim 15$ mK), a temperature low enough for the approximation $k_B T \ll \varepsilon_F$ to be valid. The standard low-frequency (13 Hz) ac lock-in technique was employed for the resistivity measurement with a low excitation current (10 nA for $B \lesssim 1$ T and 0.5 nA for higher magnetic fields) to prevent electron heating. For the magnetic field sweep, we adopted very slow sweep rates (0.01 T min$^{-1}$ for $B \lesssim 1$ T and 0.1 T min$^{-1}$ for higher magnetic fields), which, combined with a high data acquisition rate ($\sim 4$ data points s$^{-1}$), allow us to acquire data points dense enough to perform the numerical differentiation with respect to $B$ reliably. The slow sweep rates are also favorable in avoiding the hysteresis in the superconducting magnet that obscures the exact value of the magnetic field felt by the sample. The longitudinal and the Hall resistances measured in our Hall bar sample are translated to resistivities $ρ_{xx}$ and $ρ_{yx}$ by using the geometrical factors of the Hall bar. Then we obtained $σ_{xx}$ and $σ_{yx}$ by numerically inverting the tensor, $σ_{xx} = ρ_{xx}/(ρ_{xx}^2 + ρ_{yx}^2)$ and $σ_{yx} = ρ_{yx}/(ρ_{xx}^2 + ρ_{yx}^2)$. As mentioned earlier, spin splitting can completely be neglected for $B \lesssim 0.5$ T. Due to the spin degeneracy, the conductivities experimentally measured in this magnetic field range are simply twice as large as those without the spins; considering the spin degeneracy, the normalized conductivities are defined here as $σ_{αβ} = σ_{αβ}/(2e^2/h)$.

In figure 7, we show $d\tilde{σ}_{xy}/dB$ attained by the numerical differentiation of experimentally obtained $σ_{xy}$, and $d\tilde{σ}_{xy}/dB$ approximated by equations (52) and (53) using experimentally acquired $σ_{xx}$. It can be seen by comparing figures 6 and 7 that our theory reproduces the experimentally obtained traces remarkably well. Note that the same vertical scale is used for the two figures. Both figures reveal that the approximation by equation (52) progressively worsens with decreasing magnetic field, while equation (53) remains a good approximation over the magnetic field range shown in the figure. We want to
emphasize that the good quantitative agreement, demonstrated in figure 7, between $d\tilde{\sigma}_{xy}/dB$ directly deduced from $\sigma_{xy}$ and that approximated by equation (53) using $\sigma_{xx}$ is achieved without any fitting parameter. In figure 7, we also plot the rhs of equation (3) with the experimentally obtained $\sigma_{xx}$ and $\beta = 2\tau_m/\tau_q$ is also plotted by a dotted–dashed blue line in (b). The traces are separately plotted in (a) and/or (b) for clarity.

For higher magnetic fields, spin splitting manifests itself as the splitting of the peaks in $\sigma_{xx}$ and $d\tilde{\sigma}_{xy}/dB$. The peaks take place at the conditions $\varepsilon_F = E_N + g^*\sigma \mu_B B$ ($N = 0, 1, 2, \ldots, \sigma = \pm 1/2$, and $g^*$ represents the g factor including ($B$-dependent) exchange enhancement), instead of $\varepsilon_F = E_N$ in the spin-degenerate case, and therefore equations (49) and (50) no longer describe the positions of peaks or steps between adjacent plateaus correctly. Nevertheless, concurrent occurrence of peaks in $\sigma_{xx}$ and in $d\tilde{\sigma}_{xy}/dB$ still allows us an attempt to see the applicability of equation (52), as shown in figure 8. Here $\tilde{\sigma}_{xy} = \sigma_{xy}/(e^2/h)$ again since spin degeneracy is now lifted. We see that equation (52) reproduces roughly the right order of magnitude for the height of the peaks in $d\tilde{\sigma}_{xy}/dB$, although the increase in the peak height with increasing magnetic field for $1 \ T \leq B \leq 2.5 \ T$ is at obvious variance with the behavior of $d\tilde{\sigma}_{xy}/dB$. The discrepancy is mainly ascribable to the deviation of experimental peak heights in $\sigma_{xx}$ from the $\propto 1/B$ dependence inferred from equation (49). In contrast, we find that our experimental result is well described by equation (3) in accordance with previous studies [2–8], albeit with the value of the parameter $\beta \simeq 400$ roughly 20 times larger than $2\tau_m/\tau_q$. 

![Figure 7](image1.png)

**Figure 7.** Experimental traces to be compared with figure 6: $d\tilde{\sigma}_{xy}/dB$ deduced by numerical differentiation of experimentally obtained $\sigma_{xy}$ (thin solid red line, plotted in both (a) and (b)), $d\tilde{\sigma}_{xy}/dB$ approximated by equation (53) (thick dashed green line in (a)) or by equation (52) (thin dotted green line in (b)) calculated using experimentally obtained $\sigma_{xx}$. The rhs of equation (3) with the experimentally obtained $\sigma_{xx}$ and $\beta = 2\tau_m/\tau_q$ is also plotted by a dotted–dashed blue line in (b). The traces are separately plotted in (a) and/or (b) for clarity.

![Figure 8](image2.png)

**Figure 8.** Experimental traces for higher magnetic field range: $d\tilde{\sigma}_{xy}/dB$ deduced by numerical differentiation of experimentally obtained $\sigma_{xy}$ (thin solid red line, plotted in both (a) and (b)), $d\tilde{\sigma}_{xy}/dB$ approximated by equation (52) calculated using experimentally obtained $\sigma_{xx}$ (thick dashed green line in (a)) and the rhs of equation (3) with the experimentally obtained $\sigma_{xx}$ and $\beta \simeq 400$ (dotted–dashed blue line in (b)). The traces are separately plotted in (a) and/or (b) for clarity.
6. Discussion

The relation between \( \sigma_{xx} \) and \( \sigma_{xy} \) is already implicit in equations (18) and (19), since both of the components derive from the same set of Green’s functions \( G_N(\varepsilon) \) \( (N = 0, 1, 2, \ldots) \), or from the same DOS; note that, once the DOS is given, both imaginary and real parts of \( G_N(\varepsilon) \) are known by equation (11) and by the Kramers–Kronig relation, respectively. We have shown in section 4 that the relation can be explicitly written down as equation (42), or approximately as equation (45), if we assume a simple form given by equation (12) for the Green’s function corresponding to the Lorentzian broadening of the Landau levels equation (8). It might be argued that the expression equation (12) is too crude to represent a 2DES under a magnetic field. We expect, however, that improvement in \( G_N(\varepsilon) \) does not alter the relation equation (42) to a large extent (if we keep ourselves within the framework of the approximate relation between the conductivity tensor and the Green’s function represented by equations (18) and (19)), so long as the resultant DOS does not significantly deviate from the Lorentzian lineshape. An important point we would like to stress is that the relation equation (42) is inherent in the expressions of \( \sigma_{xx} \) and \( \sigma_{xy} \) and requires no external source, e.g. the inhomogeneity in the electron density.

In equations (18) and (19), we have neglected a number of effects known to take place in a 2DES subjected to a magnetic field. These include the localization, the formation of the edge states (stripes of compressible states parallel to the edge of the sample interleaved with incompressible regions) and the electron–electron interaction. We have also neglected spins altogether as mentioned in section 5. Due to the localization in the tails of Landau level peaks, the width of the peaks in \( \sigma_{xx} \) will become narrower than what is shown in figures 2 and 4 for the high magnetic field region where overlap between adjacent Landau level peaks can be neglected. The electron–electron interaction will engrave additional minima on the peaks of \( \sigma_{xx} \) between adjacent integral quantum Hall states for \( N < 2 \) Landau levels via the fractional quantum Hall effect [33], and also affect the height and shape of the peaks for higher Landau levels through forming the (probably incomplete) charge density wave states [34, 35]. For a long-range impurity potential, the peaks will be altered also by the network of compressible and incompressible stripes formed around valleys or hills of the impurity potential [36]. Strictly speaking, therefore, our theory applies only to the low magnetic field region where these effects are negligibly small. This is exactly the region we have employed in the comparison with the experimental result in figure 7. The excellent agreement between the theory and experiment attests to the correctness of our theory were it not for the additional effects neglected in the theory. The slight difference in the lineshape between theoretical (figure 6) and experimental (figure 7) traces, with the theoretical trace showing asymmetry between sharp maxima and rather rounded minima, is attributable to the use of constant \( e\mathbf{F} \) in the theory; in the experiment, \( e\mathbf{F} \) is expected to oscillate with magnetic field to keep the electron density \( n_e \) constant, resulting in more symmetric peaks and dips [37].

In the higher magnetic field regime, we envisage better agreement between theoretical and experimental results by modifying our theory to include the effects neglected in the present paper listed above, which is the subject of our future study. In the high magnetic field regime, however, we are unable to rule out the possibility that the inhomogeneity in \( n_e \) is the dominant source of the experimentally observed relation equation (1) (or equation (3) as shown in figure 8), as suggested by previous studies [8, 10, 11]; the effect of the inhomogeneity is expected to gain more significance at higher magnetic fields, since the difference in the Hall resistivity \( \Delta\rho_{xy} \) between two points differing in the electron density by \( \Delta n_e \), \( \Delta\rho_{xy} \approx \Delta n_e B/(n_e^2 e) \), increases with \( B \). Note that, in realistic samples, both microscopic inhomogeneity owing to the random distribution of the dopants and macroscopic inhomogeneity resulting from the technical difficulties in the molecular beam epitaxy are virtually impossible to be completely eliminated.

7. Conclusions

We have calculated the diagonal \( (\sigma_{xx}) \) and off-diagonal \( (\sigma_{xy}) \) components of the conductivity tensor in the quantum Hall system by the linear response theory, neglecting the correction from the current vertex part. A Lorentzian lineshape with the width \( \Gamma \) independent of the magnetic field was assumed for the broadening of the Landau levels by the short-range impurity potential. The corresponding simple approximation for the Green’s function equation (12) allowed us to obtain analytic formulae for both \( \sigma_{xx} \) and \( \sigma_{xy} \), given by equations (35) and (36), respectively, for \( k_B T \ll e\mathbf{F} \). The formulae asymptotically approach the semiclassical formulae at low magnetic fields. Inspection of the formulae reveals that \( d\sigma_{xy}/dB \) is proportional to \( B\sigma_{xx}^2 \) (equation (45)) at high magnetic fields where \( \Gamma \ll \hbar\omega_c \). This comprises a possible alternative route to explain, without resorting to the inhomogeneity in the electron density, the well-known empirical relation between \( \sigma_{xx} \) and \( \sigma_{xy} \).

To account for the long-range nature of the impurity potential in a GaAs/AlGaAs 2DES, a slight modification was made by introducing two types of scattering times, the quantum scattering time \( \tau_q \) and the momentum relaxation time \( \tau_m \), yielding equations (49) and (50) for \( \sigma_{xx} \) and \( \sigma_{xy} \), respectively. The resultant relation between the two components, equation (53), is found to be in quantitative agreement with the experimental result obtained in the GaAs/AlGaAs 2DES at the magnetic field range where the spin splitting, the localization, the formation of the edge states, the electron–electron interaction, etc, can be neglected.

Acknowledgments

This work was supported by a Grant-in-Aid for Scientific Research (B) (20340101) from the Ministry of Education, Culture, Sports, Science and Technology (MEXT) and by the National Institutes of Natural Sciences undertaking Forming Bases for Interdisciplinary and International Research through Cooperation Across Fields of Study and Collaborative
In the derivation of equations (35) and (36), we have made no assumption on the strength of the magnetic field. Therefore the equations should, in the low field limit, asymptotically coincide with the well-known semiclassical expressions

\[ \sigma^{SC}_{xx} = \frac{\sigma_0}{1 + (\omega_0 \tau)^2} \] (A.1)

\[ \sigma^{SC}_{xy} = -\frac{\sigma_0 \omega_0 \tau}{1 + (\omega_0 \tau)^2} = -\frac{n_e e^2}{B} + \frac{1}{\omega_0 \tau} \sigma^{SC}_{xx}, \] (A.2)

with \( \sigma_0 = n_e e^2 / m^* = \varepsilon_F e^2 / (2\pi \hbar^2) \) or, in the normalized forms,

\[ \tilde{\sigma}^{SC}_{xx} = \frac{2\gamma}{1 + 4\gamma^2} \left( X_F + \frac{1}{2} \right) \] (A.3)

\[ \tilde{\sigma}^{SC}_{xy} = -\frac{1}{1 + 4\gamma^2} \left( X_F + \frac{1}{2} \right) = -\left( X_F + \frac{1}{2} \right) + 2\gamma \tilde{\sigma}^{SC}_{xx}. \] (A.4)

Since \( \text{Fsinh}(X_F, \gamma) \to 1 \) with \( \gamma \to \infty \), it is ready to see \( \tilde{\sigma}_{xx} \to \tilde{\sigma}^{SC}_{xx} \) with \( B \to 0 \) in equation (35). From equations (35) and (36), we find

\[ \tilde{\sigma}_{xy}(X_F, \gamma) = -\text{Fsinh}(X_F, \gamma) - \gamma \text{Fsin}(X_F, \gamma) \]

\[ + 2\gamma \tilde{\sigma}_{xx}(X_F, \gamma). \] (A.5)

Noting that \( \text{Fsinh}(X_F, \gamma) \to (X_F + 1/2) \) and \( \gamma \text{Fsin}(X_F, \gamma) \to 0 \) with \( \gamma \to \infty \), we can also perceive \( \tilde{\sigma}_{xy} \to \tilde{\sigma}^{SC}_{xy} \) with \( B \to 0 \).
