Search for singly and pair-produced leptoquarks coupling to third-generation fermions in proton-proton collisions at $\sqrt{s} = 13$ TeV

The CMS Collaboration

Abstract

A search for leptoquarks produced singly and in pairs in proton-proton collisions is presented. We consider the leptoquark (LQ) to be a scalar particle of charge $-1/3e$ coupling to a top quark plus a tau lepton ($t\tau$) or a bottom quark plus a neutrino ($b\nu$), or a vector particle of charge $+2/3e$, coupling to $tv$ or $b\tau$. These choices are motivated by models that can explain a series of anomalies observed in the measurement of B meson decays. In this analysis the signatures $t\tau\nu b$ and $t\tau\nu$ are probed, using data recorded by the CMS experiment at the CERN LHC at $\sqrt{s} = 13$ TeV and that correspond to an integrated luminosity of 137 fb$^{-1}$. These signatures have not been previously explored in a dedicated search. The data are found to be in agreement with the standard model prediction. Lower limits at 95% confidence level are set on the LQ mass in the range 0.98–1.73 TeV, depending on the LQ spin and its coupling $\lambda$ to a lepton and a quark, and assuming equal couplings for the two LQ decay modes considered. These are the most stringent constraints to date on the existence of leptoquarks in this scenario.

1 Introduction

Experimental evidence has promoted the standard model (SM) to the role of a reference theory of the physics of elementary particles. Despite the theory’s successes, there are several fundamental aspects of observed particle physics that lack a complete explanation. One of these is the symmetry between the quark and lepton families. Possible explanations have been offered by several models that extend the SM, such as grand unified theories \[1–4\], technicolor models \[5–8\], compositeness scenarios \[9,10\], and \(R\)-parity violating supersymmetry \[11–20\]. These theories foresee a new particle that carries both lepton number \(L\) and baryon number \(B\), and is generically referred to as a “leptoquark” (LQ).

A leptoquark has a fractional electric charge, and can be either a scalar particle (LQ\(_S\), with a spin of 0), or a vector particle (LQ\(_V\), with a spin of 1), with \(3B + L\) equal to either 2 or 0. At hadron colliders, leptoquarks can be produced in pairs, or singly in association with a lepton \[21,22\], as illustrated by the Feynman diagrams in Fig. 1. For LQ\(_S\) pair production, the cross section depends only on the LQ\(_S\) mass for the range of LQ mass and \(\lambda\) values investigated in this search, while for LQ\(_V\) it may depend on additional parameters \[23\], to comply with constraints imposed by unitarity at high energy scales. For singly produced leptoquarks, the cross section further depends on the couplings of the LQ to the quark and the lepton, and on the quark flavor.

Leptoquarks have recently gained enhanced interest, as they may provide an explanation for a series of anomalies observed in the measurement of B meson decays in charged-current \(b \to c\ell\nu\) \[24–33\] and neutral-current \(b \to s\ell\ell\) \[34–41\] processes. The solutions proposed to explain these anomalies favor effective couplings to third-generation SM fermions at the TeV scale, leading to processes that may be accessible at the CERN LHC. In particular, the model of Ref. \[42\] predicts a charge \(-1/3e\) LQ\(_S\), with \(3B + L = 2\), decaying to a top quark and a \(\tau\) lepton \((t\tau\nu)\), or a bottom quark and a neutrino \((b\nu\tau)\), while the model presented in Ref. \[43\] contains a charge \(+2/3e\) LQ\(_V\), with \(3B + L = 0\), decaying to a top quark and an antineutrino \((t\bar{\nu}\tau)\) or a bottom quark and an anti-\(\tau\) lepton \((b\bar{\tau})\). Each model includes a charge-conjugate leptoquark and prefers a region of parameter space that gives equal branching fractions for the two allowed decays, rendering the \(t\tau\nu(b)\) signature as the most frequent for pair-produced leptoquarks.

The analysis described in this Letter investigates the existence of leptoquarks produced in pairs with decays leading to \(\tau\ell\nu\) signature, or singly with the decay leading to \(\tau\ell\nu\). The models of Refs. \[42,43\] are considered in this analysis, relying on the implementations described in Refs. \[44,45\]. In these models, the parameters of interest for determining the cross section are: the LQ mass; for LQ\(_V\), a dimensionless coupling \(k\), set to 1 (Yang–Mills case) or 0 (minimal coupling case) \[23\]; and the LQ coupling \((\lambda)\) to the lepton and quark, which affects the cross section for single LQ production. We note that the analysis is designed to be agnostic to the charge of the LQ, and is thus sensitive also to models with up-type scalar LQ and down-type vector LQ, which are not directly considered below.

The most recent searches for leptoquarks have been performed at \(\sqrt{s} = 13\) TeV by the ATLAS and CMS Collaborations for couplings to \((t\tau, b\nu)\) and \((t\nu, b\tau)\) \[46–53\] and for couplings to other quark-lepton pairs \[51,54–57\].

Differently from previous searches that have separately considered single or pair LQ production, the present analysis strategy is devised to search for both production mechanisms simultaneously. The \(t\tau\nu(b)\) signatures are analyzed for the first time considering the inclusive hadronic decay channels of the top quark and \(\tau\) lepton. We include a dedicated selection for the case of a large LQ-t mass splitting giving rise to a Lorentz-boosted top quark, whose decay
Figure 1: Feynman diagrams for dominant leptoquark production modes at leading order: pairwise (left), and in combination with a lepton (right). In the scenarios considered the LQs may couple to $t\tau$ or $b\nu$, while the LQ$_V$ may couple to $t\nu$ or $b\tau$.

products may not be resolved as individual jets.

The search is based on a data sample of proton-proton (pp) collisions at a center-of-mass energy of 13 TeV recorded by the CMS experiment at the CERN LHC in the years 2016–18, corresponding to an integrated luminosity of 137 fb$^{-1}$.

2 The CMS detector

The central feature of the CMS detector is a 3.8 T superconducting solenoid magnet with an inner diameter of 6 m. Within the magnet volume are the following subdetectors: a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter. Muons are detected in gas-ionization chambers embedded in the steel flux-return yoke outside the solenoid. In addition, two steel and quartz-fiber hadron forward calorimeters extend the detection coverage to regions close to the beam pipe. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [58]. Events of interest are selected using a two-tiered trigger system [59]. The first level, composed of custom hardware processors, uses information from the calorimeters and muon detectors to select events at a rate of around 100 kHz within a fixed time interval of about 4 $\mu$s. The second level, known as the high-level trigger, consists of a farm of processors running a version of the full event reconstruction software optimized for fast processing, and reduces the event rate to around 1 kHz before data storage.

3 Simulated data samples

Monte Carlo (MC) event generators are used to simulate the SM background processes and the signal. These simulations are used to guide the design of the analysis, to estimate minor backgrounds, and to interpret the results.

Background events are generated at leading order (LO) for the $W + \text{jets}$ and $Z/\gamma^* + \text{jets}$ processes using the generator MadGraph5_aMC@NLO 2.2.2 (2.4.2) [60] for simulated events matched with 2016 (2017–18) data, while the next-to-LO (NLO) generator POWHEG 2.0 [61,66] is used for $t\bar{t}$, $tW$, and diboson processes, and MadGraph5_aMC@NLO at NLO for $t\bar{t} + W$, $t\bar{t} + Z/\gamma^*$, $tW$, and triboson production. Both MadGraph5_aMC@NLO and POWHEG are interfaced with Pythia 8.226 (8.230) [67] for parton showering and hadronization using the tune CUETP8M1 [68] or CUETP8M2T4 [69] (CP5 [70]) and the NNPDF 3.0 [71] (3.1 [72]) par-
ton distribution functions (PDFs) for simulating all 2016 (2017–18) samples. In the following, we group these backgrounds where a genuine \( \tau \) lepton is present as either “\( t \) production” or “Others”, depending on whether a top quark is produced in the SM process or not.

Signal samples are generated at LO using MADGRAPH 5 interfaced with PYTHIA for the LQ\(_S\) and LQ\(_V\) models of Refs. [42] and [43], according to the implementations of Refs. [44] and [45]. The NNPDF 3.0 [71] (3.1 [72]) parton distribution function (PDF) set is utilized with the tune CUETP8M1 [68] (CP2 [70]) for the signal events used with the 2016 (2017–18) data. The LQ mass range studied is between 0.5 and 2.3 TeV, with samples produced in steps of 0.3 TeV. We consider LQ\(_S\) (LQ\(_V\)) decaying as LQ\(_S\) → \( t\tau \) (\( t\nu \)) and LQ\(_V\) → \( b\nu \) (\( b\tau \)). Samples of pair-produced leptoquarks are generated considering both gluon-initiated and quark-initiated mechanisms. We consider equal values of \( \lambda \) for leptoquarks coupled to (\( t\tau \), \( b\nu \)) and (\( t\nu \), \( b\tau \)). Samples of singly produced LQ are generated with \( \lambda \) values 0.1, 0.5, 1, 1.5, 2, and 2.5. In the MC simulation, the kinematic distributions of singly produced leptoquarks are independent of \( \lambda \) below \( \lambda = 0.5 \) (1) in the case of LQ\(_S\) (LQ\(_V\)), and in both cases are independent of \( k \). The dependence on \( \lambda \) above these values is ascribed to the contributions of virtual LQ states in the quark-gluon fusion amplitude (Fig. 1 right) that become more and more relevant compared to the resonant LQ production for increasing values of LQ mass and \( \lambda \), and are manifest as off-shell events that tend to populate the low-mass tail.

Additional pp interactions within the same or nearby bunch crossings (pileup) are taken into account by superimposing simulated minimum bias interactions onto the hard scattering process, with a number distribution matching that observed in data. Simulated events are propagated through the full GEANT4 based simulation [73] of the CMS detector.

4 Particle reconstruction and identification

A particle-flow (PF) algorithm [74] is used to identify and reconstruct individual particles in the event (electrons, muons, photons, neutral and charged hadrons) through a combination of the information from the entire detector. These PF objects are used to reconstruct higher-level objects such as hadronically decaying \( \tau \) leptons (\( \tau_h \)), jets, and missing transverse momentum (\( \vec{p}_T^{\text{miss}} \), taken as the negative vector sum of the transverse momenta (\( \vec{p}_T \)) of all reconstructed particles in an event. The magnitudes of \( \vec{p}_T \) and \( \vec{p}_T^{\text{miss}} \) are referred to as \( p_T \) and \( p_T^{\text{miss}} \), respectively.

Jet candidates are reconstructed from PF candidates using the anti-\( k_T \) clustering algorithm [75] with a distance parameter of 0.8 (“AK8 jet”) or 0.4 (“AK4 jet”), and are selected requiring \( p_T > 30 \) GeV and \( |\eta| < 2.4 \). The jet energy scale (JES) is calibrated through correction factors dependent on the \( p_T \), pseudorapidity (\( \eta \)), energy density, and the area of the jet. The jet energy resolution (JER) for the simulated jets is corrected to reproduce the resolution observed in data [76].

The AK8 jet candidates are required to have \( p_T > 180 \) GeV, \( |\eta| < 2.4 \), and to be separated by \( \Delta R > 0.8 \) from an identified \( \tau_h \), where \( \Delta R \equiv \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2} \) and \( \phi \) is the azimuthal angle. They are selected if they are identified as originating from a W boson decaying to \( qq' \) (denoted as “W jets”) by using a pruning algorithm [77] or from a top quark decaying fully hadronically (“\( t \) jets”). The mass of the pruned AK8 W jet is required to be within the range 65–105 GeV to select candidates consistent with W bosons and to reject quark and gluon jets. The discrimination between W jets and quark and gluon jets is further improved by requiring the ratio \( \tau_{21} \) to be less than 0.35 or 0.45, depending on the year of data taking, where \( \tau_{21} \equiv \tau_2 / \tau_1 \) and the \( N \)-subjettiness \( \tau_n \) has the property that it attains a smaller value the more nearly the jet
resembles a collection of $n$ subjets [78]. In a similar way, an AK8 jet may be identified as arising from the fully hadronic decay of a top quark. These $t$ jets are required to have $p_T > 400 \text{ GeV}$, mass of the jet reconstructed through the modified mass drop tagger algorithm [79, 80] between 105 and 220 GeV, and $\tau_{32} \equiv \tau_3/\tau_2$ less than 0.81.

The $\tau_h$ candidates are reconstructed with the hadron-plus-strips algorithm [81], which is seeded with AK4 jets. This algorithm reconstructs $\tau_h$ candidates in the one-prong, one-prong plus $\pi^0(s)$, and three-prong decay modes. A discriminator based on a multivariate analysis, including isolation [61] as well as lifetime information, is used to reduce the frequency of jets being misidentified as $\tau_h$ candidates. The typical working point used in this analysis has an efficiency of $\approx 60\%$ for a genuine $\tau_h$, with a misidentification rate for quark and gluon jets of $\approx 0.1\%$ [81]. Electrons and muons misidentified as $\tau_h$ candidates are suppressed using criteria based on the consistency among the measurements in the tracker, the calorimeters, and the muon detectors. The $\tau_h$ candidates are required to have a minimum $p_T$ of 20 GeV and $|\eta| < 2.3$.

Jets arising from a bottom quark ("b jets") are identified among AK4 jets using the combined secondary vertex algorithm [82]. We choose a “loose” working point that has an efficiency of 85% for genuine b jets and a rejection of 90% of light-flavor jets. The b jets are considered regardless of whether they are contained in top quark candidates.

Further requirements are imposed on the AK4 jets used in the construction of top and bottom quark candidates. These are required to have $p_T > 30 \text{ GeV}$ and $|\eta| < 2.4$, and to be separated by $\Delta R > 0.4 \ (0.8)$ from an identified $\tau_h$ (W jet).

A hadronically decaying top quark candidate is reconstructed considering three cases: an AK8 jet identified as a $t$ jet, a pair comprising an AK4 jet and a W jet and having combined mass closest to the top quark mass among such pairs, and the triplet of AK4 jets having a mass closest to the top quark mass. The $b$ tagging information is not used in any of these three reconstruction processes. These cases correspond to the three possible topologies of hadronic top quark decay and are referred to as “fully merged”, “partially merged”, and “resolved”, respectively. The reconstruction considers these cases in the order just described, removing the objects contained in a candidate from further consideration to ensure that the categories are exclusive. The efficiency for identifying W, b, and t jets in simulation is corrected to match the results found in data [82, 83].

To select events from processes with fully hadronic states, a veto on electrons and muons is applied. Electron candidates are reconstructed by combining the information from the ECAL and the silicon tracker, and are identified if they satisfy quality requirements and isolation as specified in [84]; they are selected if they have $p_T > 20 \text{ GeV}$ and $|\eta| < 2.5$. Muon candidates are reconstructed by combining the information from the muon system and the silicon tracker, and are identified if they pass additional identification criteria and isolation as specified in [85]; they are selected if they have $p_T > 20 \text{ GeV}$ and $|\eta| < 2.4$.

5 Event selection

Selected events must satisfy a trigger that requires both $p_T^{\text{miss}}$ and $H_T^{\text{miss}}$ greater than 120 GeV, $H_T^{\text{miss}}$ being the magnitude of the negative summed $\vec{p}_T$ of all the AK4 jets reconstructed with the PF algorithm.

Offline, we consider events in which both $p_T^{\text{miss}}$ and $H_T^{\text{miss}} \geq 200 \text{ GeV}$, and $H_T \geq 300 \text{ GeV}$, where $H_T$ is the scalar sum of the $p_T$ of all AK4 jets. Events entering this region are further required to contain exactly one top quark candidate, one $\tau_h$ candidate, no elec-
trons or muons, and at least one $b$ jet. Finally, the transverse mass $m_T(\tau_h, p_T^{\text{miss}}) \equiv \sqrt{2p_T(\tau_h)p_T^{\text{miss}}[1 - \cos \Delta \phi(\tau_h, p_T^{\text{miss}}))]$ has to exceed 300 GeV, where $\vec{p}_T(\tau_h)$ is the transverse momentum vector of the $\tau_h$ candidate.

From simulation we find that the total selection efficiency, accounting for both the LQ decay branching fraction and the event selection, varies between about 2 and 9% for an LQ mass in the range 0.5–2.3 TeV for pair-produced leptoquarks. For singly produced leptoquarks, taking $\lambda = 1.5$, the signal efficiency is about 0.7% for an LQ $S$ with a mass of 1.1 TeV; the corresponding number for an LQ $V$ is 2.4 (3.1)% for $k = 0$ (1) for a mass of 1.4 TeV. The efficiency decreases for higher $\lambda$ and LQ mass values. This is because of the increased impact of the virtual leptoquarks leading to the nonresonant process in which the events tend to populate the low-mass tail, as described in Section 3. The efficiency values for all the different leptoquark hypotheses and parameters investigated in this search can be found in the HEPData database [86]. The search is less sensitive to single LQ production than to pair production because of the smaller signal efficiency for higher $\lambda$ and LQ mass values and the similarity of the kinematic properties to those of the expected SM background. These effects outweigh the higher relative LQ $S$ ($LQ_V k = 0, LQ_V k = 1$) cross section for mass values of 0.5 and 0.7 TeV (0.6 and 1.2 TeV, 1.2 and 2 TeV) at values of $\lambda$ of 2 and 1.5.

The events that pass the above selection are categorized according to the number of $b$ jets ($N_{b\text{-jet}} = 1$ or $\geq 2$) and to whether the top quark candidate is selected through the fully or partially merged topology (“boosted”), or the resolved topology (“resolved”). For each of these four categories of events a distribution-based analysis is performed, searching for evidence of a signal by considering the distribution of $S_T$, which is the scalar sum of the $p_T$ of the top quark candidate, the selected $\tau_h$, and the $p_T^{\text{miss}}$. Figure 2 shows the $S_T$ distributions for the events passing the signal selection in the four categories of the analysis, while Table I gives the yields from the background estimation and the expected signal.

Table 1: Yields from the SM background estimation, data, and expected signal, for the selected events, with total (statistical+systematic) uncertainties.

| Category          | Boosted $N_{b\text{-jet}} = 1$ | Boosted $N_{b\text{-jet}} \geq 2$ | Resolved $N_{b\text{-jet}} = 1$ | Resolved $N_{b\text{-jet}} \geq 2$ |

6 Background estimation

Several SM processes contribute as backgrounds in the signal region. We treat separately the two cases in which a genuine $\tau$ lepton is present or not in the event.

The irreducible background with a real $\tau$ lepton that decays hadronically is estimated from simulated samples, and normalized to data in a control region where we expect negligible
The dominant source of contamination is the reducible background, which comprises all of the processes (mainly events composed uniquely of jets produced through the strong interaction) and a control region is defined by applying the requirements used for the signal region, except with $mT_{\text{miss}}(\tau, p_T^{\text{miss}}) < 80$ GeV and $N_{b\text{-jet}} \geq 2$.

The dominant source of contamination is the reducible background, which comprises all of the processes (mainly events composed uniquely of jets produced through the strong interaction).
tion, W + jets, and t¯t) that pass the signal region selection and in which a jet is misidentified as a τ

h candidate. We estimate this background entirely from data by applying misidentification weights w to the yields of events selected with the same requirements as the signal region, except that the τ

h must pass a looser identification requirement and fail the nominal one. We refer to this sample as the application region. An estimate from simulation of the number of events entering the application region while having a genuine τ

h is subtracted from the application region yields. The weight w of each event depends on the probability f that a misidentified τ

h candidate passing the relaxed criteria also passes the nominal criteria, and is given by f/(1 − f). The probability f is parameterized as a function of the pT and |η| of the jet associated with the selected τ

h candidate, within ∆R(jet, τ

h ) < 0.4. It is measured in a large data sample with a high fraction of jets misidentified as τ

h. To select this sample the signal region requirements are modified by removing the thresholds on pTmiss and HmissT and requiring instead the presence of a muon with pT greater than 60 GeV. The requirement Nb-jet ≥ 1 is replaced by Nb-jet = 0, to suppress t¯t events with genuine τ

h, and the requirement on mT(τ

h , pTmiss) is replaced by mT(τ

h , µ) > 120 GeV, to suppress Drell–Yan events. In the resultant sample, more than 90% of the events have jets misidentified as τ

h. To select this sample the signal region selection is replaced with a requirement 120 < mT(τ

h , pTmiss) < 300 GeV. This region is verified to have a composition of background processes similar to that of the signal region but is dominated by events with a misidentified τ

h candidate, as determined from MC simulation. We find good agreement between the data and the estimated background in this region, as well as in a larger one with the Nb-jet requirement released. The observed difference does not exceed 12%, and this value is therefore assigned as the systematic uncertainty in the background estimated using this method.

7 Systematic uncertainties

Systematic uncertainties from various sources are propagated to both the shape and normalization of the distributions in the discriminating variable ST. The systematic uncertainties affect both the signal and the background, particularly the minor backgrounds (t production or “Others”) that are derived relying on the MC simulation, while the main background (τ misidentification) is estimated from data.

The shape uncertainties vary according to the background process, ST bin, and year of data taking. Thus in the following, we quote a range of values, reflecting the minimum and maximum uncertainties observed under the various conditions. The effect of the uncertainty on the simulation of pileup is estimated by varying the inelastic cross section [87] used in the simulation by 5%. This results in an uncertainty associated with the background of between 1 and 6%, and of 1% associated with the signal. The uncertainty in the acceptance associated with the PDFs is evaluated in accordance with the PDF4LHC recommendations [88], using the PDF4LHC15 Hessian PDF set with 100 eigenvectors, and is found to be less than 5% for the signal. The uncertainty related to the trigger is between 1 and 2%, for both the background and the signal. The jet four-momenta are varied within the JES and the JER uncertainties [76], resulting in an effect that ranges between 1 and 35% for the background and up to 2.5% for the signal. The above uncertainties are correlated across the years, while those discussed below are treated as uncorrelated, as they are dominated by statistical uncertainties. Corrections related to the b tagging are varied by the uncertainties that are measured with control samples in data and simulation [82], giving a systematic uncertainty in the yields in the range 3–10%
for the background and 8–10% (13–23%) for single (pair) LQ production. Analogously, we take into account the uncertainty in the $\tau_h$ energy scale and identification [81], which amounts to 1–5% (less than 1%) and 5–13 (13–20)% for the background (signal). The W and t jet tagging uncertainty amounts to 2–11 (1–4)% and 3–15 (7–14)% for the background (signal). For all of the background processes, the statistical uncertainty in the samples used is included in the systematic uncertainty.

The sources of systematic uncertainty that affect only the normalization are the uncertainties in the cross sections of the backgrounds estimated from simulation (5% for top quark production and 30% for the remaining backgrounds), the uncertainty in the misidentified $\tau_h$ contribution, whose value of 12% is assigned from the consistency test discussed in Section 6, and the uncertainty in the integrated luminosity. The integrated luminosities of the 2016–18 data-taking periods are individually known with uncertainties in the 2.3–2.5% range [89–91], while the total Run 2 (2016–18) integrated luminosity has an uncertainty of 1.8%, the improvement in precision reflecting the (uncorrelated) time evolution of some systematic effects.

8 Results

Figure 2 and Table 1 show that the data are in agreement with the background expectations from the SM in all of the event categories investigated. We proceed with setting upper limits at 95% confidence level (CL) on the cross sections for the production of leptoquarks in pairs, $\sigma(pp \rightarrow LQLQ)$, and singly, $\sigma(pp \rightarrow \ell LQ)$, for $LQS (\ell = v)$, and $LQV (\ell = \tau)$. We use the CL$_s$ criterion [92, 93] with binned templates of both background and signal as given by the distributions of Fig. 2. For each category and each bin of $S_T$, the observed number of events is fitted by a Poisson distribution, whose mean is the sum of the total SM expectation, determined as described in Section 6, and a potential signal contribution determined from simulation. The systematic uncertainties described in Section 7 are considered as nuisance parameters, with a lognormal distribution for the normalization parameters and a Gaussian distribution for systematic uncertainties affecting the shape.

The observed and expected upper limits on $\sigma(pp \rightarrow LQLQ)$, $\sigma(pp \rightarrow \ell LQ)$, and the case where both pair and single production mechanisms are considered simultaneously, $\sigma(pp \rightarrow LQLQ) + \sigma(pp \rightarrow \ell LQ)$, as a function of the mass of the leptoquarks are shown in Figs. 3–5 where the leptoquarks are $LQS$, $LQV k = 0$, and $LQV k = 1$, respectively. The uncertainty in the production cross section shown in these figures is given by the sum in quadrature of contributions arising from the PDFs and the renormalization and factorization scales. To estimate the latter, we consider the effects of multiplying these scales by factors of 0.5 and 2 [94–96]. For single LQ production, the limits are shown for fixed values of $\lambda = 1.5$ and 2.5. Only values of $\lambda$ less than 2.5 are considered, since higher values are excluded by constraints from electroweak precision measurements [97]. The bands represent the one- and two-standard deviation variations of the expected limit. The solid blue curve indicates the theoretical prediction of $\sigma(pp \rightarrow LQLQ)$ and $\sigma(pp \rightarrow \ell LQ)$, calculated at LO except for the pair production of $LQS$, computed using NLO quantum chromodynamics corrections [98] and the model implementation in Ref. [45]. The intersection of the blue and the solid (dotted) black lines determines the observed (expected) lower limit on the LQ mass. Table 2 summarizes the observed and expected lower limits on the LQ mass inferred from Figs. 3–5 for the three cases, $LQS$, $LQV k = 0$, and $LQV k = 1$. The observed limits are, respectively, 0.98–1.02, 1.34–1.41, and 1.69–1.73 TeV for values of $\lambda$ between 1.5 and 2.5, based on the simultaneous search for single and pair production. The table also reports exclusion limits for the separate searches for single and pair production.
Table 2: Lower limits on the mass in TeV of the leptoquarks $LQ_S$, $LQ_V^k = 0$, and $LQ_V^k = 1$, based on the pair- and single-production mechanisms taken either separately or together. These lower limits are derived from the intersection of the observed 95% CL upper limits on the signal cross section and the signal cross section in Figs. 3–5. The results of the searches that depend on the $\lambda$ parameter are given for values of 1.5 and 2.5. The expected limits are given in parentheses.

|         | $LQ_S$ (TeV) | $LQ_V^k = 0$ (TeV) | $LQ_V^k = 1$ (TeV) |
|---------|-------------|-------------------|-------------------|
| **Pair** |             |                   |                   |
| $\lambda = 1.5$ | 0.95 (1.03) | 1.29 (1.39)       | 1.65 (1.77)       |
| $\lambda = 2.5$ |            |                   |                   |
| **Single** |             |                   |                   |
| $\lambda = 1.5$ | 0.55 (0.56) | 0.75 (0.81)       | 1.03 (1.12)       |
| $\lambda = 2.5$ |            |                   |                   |
| **Pair+Single** |         |                   |                   |
| $\lambda = 1.5$ | 0.98 (1.06) | 1.02 (1.10)       | 1.34 (1.46)       |
| $\lambda = 2.5$ |            |                   |                   |

The combination of the two production mechanisms extends the exclusion on the LQ mass by 30–120 GeV depending on the type of LQ. These exclusions represent the most stringent limits to date on the existence of $LQ_S$ ($LQ_V$) coupled to $t \tau$, $b \nu$, and $t \nu$, $b \tau$ or $t \tau$ ($b \nu$, $t \nu$, $b \tau$) under the assumption of equal couplings to the lepton-quark pairs. Comparing the cases of $\lambda = 1.5$ and 2.5 in Figs. 3–5, one can see how the upper limits on the cross section increase at higher LQ masses and $\lambda$ values, as a result of an increasing relative contribution of virtual LQ states in single LQ production, as discussed in Section 3, which degrades the sensitivity of the search.

Figure 6 gives the observed and expected exclusion on the existence of leptoquarks in the $\lambda - m_{LQ}$ plane, for the single and pair production mechanisms and their combination. For $LQ_V$, the gray area shows the 95% CL band preferred by the B physics anomalies [43], which is given by $\lambda = C m_{LQ}$, where $C = \sqrt{0.7 \pm 0.2}$ TeV$^{-1}$ and $m_{LQ}$ is expressed in TeV. A relevant portion of this parameter space is excluded.

9 Summary

A search for leptoquarks coupled to third-generation fermions, and produced in pairs and singly in association with a lepton, has been presented. The leptoquark (LQ) may couple to a top quark and a $\tau$ lepton ($t \tau$) or a bottom quark and a neutrino ($b \nu$, scalar LQ) or else to $t \nu$ and $b \tau$ (vector LQ), resulting in the $t \tau \nu b$ and $t \tau \nu$ signatures. The channel in which both the top quark and the $\tau$ lepton decay hadronically is investigated, including the case of a large $LQ-t$ mass splitting giving rise to a Lorentz-boosted top quark, whose decay daughters may not be resolved as individual jets. This particular signature has not been previously examined in searches for physics beyond the standard model. The data used corresponds to an integrated luminosity of 137 fb$^{-1}$ collected with the CMS detector at the CERN LHC in proton-proton collisions at $\sqrt{s} = 13$ TeV. The observations are found to be in agreement with the standard model predictions. Exclusion limits are given in the plane of the LQ-lepton-quark vertex coupling $\lambda$ and the LQ mass for scalar and vector leptoquarks. The range of lower limits on the LQ mass, at 95% confidence level, is 0.98–1.73 TeV, depending on $\lambda$ and the leptoquark spin. These results represent the most stringent limits to date on the existence of such leptoquarks for the case of equal couplings to the lepton-quark pairs. They allow a relevant portion of the parameter space preferred by the B-physics anomalies in several models [42, 43] to be excluded.

Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully...
Figure 3: The observed and expected (solid and dotted black lines) 95% CL upper limits on \(\sigma(pp \rightarrow LQ_S \bar{LQ}_S)\) (upper), \(\sigma(pp \rightarrow vLQ_S)\) with \(\lambda = 1.5\) and 2.5 (middle left and right), and \(\sigma(pp \rightarrow LQ_S \bar{LQ}_S) + \sigma(pp \rightarrow vLQ_S)\) with \(\lambda = 1.5\) and 2.5 (lower left and right), as a function of the mass of the \(LQ_S\). The limits apply under the assumption of equal couplings for the \(LQ\) decay to each of the two allowed lepton flavor pairings. The bands represent the one- and two-standard deviation variations of the expected limit. The solid blue curve indicates the theoretical predictions at LO, except for pair-produced \(LQ_S\), for which NLO values are used based on NLO quantum chromodynamics corrections [98] and the model implementation in Ref. [45].
Figure 4: The observed and expected (solid and dotted black lines) 95% CL upper limits on \( \sigma(pp \rightarrow LQ V) \) (upper), \( \sigma(pp \rightarrow \tau LQ V) \) with \( \lambda = 1.5 \) and 2.5 (middle left and right), and \( \sigma(pp \rightarrow LQ V) + \sigma(pp \rightarrow \tau LQ V) \) with \( \lambda = 1.5 \) and 2.5 (lower left and right), as a function of the mass of the \( LQ V \), with \( k = 0 \). The limits apply under the assumption of equal couplings for the \( LQ \) decay to each of the two allowed lepton flavor pairings. The bands represent the one- and two-standard deviation variations of the expected limit. The solid blue curve indicates the theoretical predictions at LO.
Figure 5: The observed and expected (solid and dotted black lines) 95% CL upper limits on $\sigma(pp \to \text{LQ}_V\ell\ell)$ (upper), $\sigma(pp \to \tau\text{LQ}_V)$ with $\lambda = 1.5$ and 2.5 (middle left and right), and $\sigma(pp \to \text{LQ}_V\ell\ell) + \sigma(pp \to \tau\text{LQ}_V)$ with $\lambda = 1.5$ and 2.5 (lower left and right), as a function of the mass of the LQ$_V$, with $k = 1$. The limits apply under the assumption of equal couplings for the LQ decay to each of the two allowed lepton flavor pairings. The bands represent the one- and two-standard deviation variations of the expected limit. The solid blue curve indicates the theoretical predictions at LO.
Figure 6: The observed and expected 95% CL LQ exclusion limits in the plane of the LQ-lepton-quark coupling and the mass of the LQ for single (brown lines) and pair (blue lines) production, and considering their sum (black lines). Regions to the left of the lines are excluded. The upper plot pertains to an LQ with equal couplings to tτ and bν, while the lower plots are for an LQV assuming k = 0 (left) and 1 (right) and equal couplings to τν and bτ. For LQV, the gray area shows the band preferred (95% CL) by the B physics anomalies: \( \lambda = C m_{LQ} \), where \( C = \sqrt{0.7 \pm 0.2 \text{ TeV}} \) and \( m_{LQ} \) is expressed in TeV [43].

Acknowledgments: We acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RIF (Cyprus); SENESCYT (Ecuador); MoER, ERC PUT and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); NKFIA (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MON (Montenegro); MIBE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Duba); MON, RosAtom, RAS, RFBR, and NRC KI (Russia); MESTD (Serbia); SEIDI, CPAN, PCTI, and FEDER (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR, and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

University of Puerto Rico, Mayaguez, USA
S. Malik, S. Norberg

Purdue University, West Lafayette, USA
V.E. Barnes, R. Chawla, S. Das, L. Gutay, M. Jones, A.W. Jung, G. Negro, N. Neumeister, C.C. Peng, S. Piperov, A. Purohit, H. Qiu, J.F. Schulte, M. Stojanovic, N. Trevisani, F. Wang, A. Wildridge, R. Xiao, W. Xie

Purdue University Northwest, Hammond, USA
J. Dolen, N. Parashar

Rice University, Houston, USA
A. Baty, S. Dildick, K.M. Ecklund, S. Freed, F.J.M. Geurts, M. Kilpatrick, A. Kumar, W. Li, B.P. Padley, R. Redjimi, J. Roberts, J. Rorie, W. Shi, A.G. Stahl Leiton

University of Rochester, Rochester, USA
A. Bodek, P. de Barbaro, R. Demina, J.L. Dulemba, C. Fallon, T. Ferbel, M. Galanti, A. Garcia-Bellido, O. Hindrichs, A. Khukhunaishvili, E. Ranken, R. Taus

Rutgers, The State University of New Jersey, Piscataway, USA
B. Chiarito, J.P. Chou, A. Gandrakota, Y. Gershtein, E. Halkiadakis, A. Hart, M. Heindl, E. Hughes, S. Kaplan, O. Karacheban, I. Laflotte, A. Lath, R. Montalvo, K. Nash, M. Osherson, S. Salur, S. Schnetzer, S. Somalwar, R. Stone, S.A. Thayil, S. Thomas, H. Wang

University of Tennessee, Knoxville, USA
H. Acharya, A.G. Delannoy, S. Spanier

Texas A&M University, College Station, USA
O. Bouhali, M. Dalchenko, A. Delgado, R. Eusebi, J. Gilmore, T. Huang, T. Kamon, H. Kim, S. Luo, S. Malhotra, R. Mueller, D. Overton, L. Perniê, D. Rathjens, A. Safonov

Texas Tech University, Lubbock, USA
N. Akchurin, J. Damgov, V. Hegde, S. Kunori, K. Lamichhane, S.W. Lee, T. Mengke, S. Muthumuni, T. Peltola, S. Undleeb, I. Volobouev, Z. Wang, A. Whitbeck

Vanderbilt University, Nashville, USA
E. Appelt, S. Greene, A. Gurrola, R. Janjam, W. Johns, C. Maguire, A. Melo, H. Ni, K. Padeken, F. Romeo, P. Sheldon, S. Tuo, J. Velkovska

University of Virginia, Charlottesville, USA
M.W. Arenton, B. Cox, G. Cummings, J. Hakala, R. Hirosky, M. Joyce, A. Ledovskoy, A. Li, C. Neu, B. Tannenwald, Y. Wang, E. Wolfe, F. Xia

Wayne State University, Detroit, USA
P.E. Karchin, N. Poudyal, P. Thapa

University of Wisconsin - Madison, Madison, WI, USA
K. Black, T. Bose, J. Buchanan, C. Caillol, S. Dasu, I. De Bruyn, P. Everaerts, C. Galloni, H. He, M. Herndon, A. Hervé, U. Hussain, A. Lanaro, A. Loeliger, R. Loveless, J. Madhusudanan, Sreekala, A. Mallampalli, D. Pinna, A. Savin, V. Shang, V. Sharma, W.H. Smith, D. Teague, S. Trembath-reichert, W. Vetens
†: Deceased
1: Also at Vienna University of Technology, Vienna, Austria
2: Also at Institute of Basic and Applied Sciences, Faculty of Engineering, Arab Academy for Science, Technology and Maritime Transport, Alexandria, Egypt, Alexandria, Egypt
3: Also at Université Libre de Bruxelles, Bruxelles, Belgium
4: Also at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France
5: Also at Universidade Estadual de Campinas, Campinas, Brazil
6: Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil
7: Also at UFMS, Nova Andradina, Brazil
8: Also at Universidade Federal de Pelotas, Pelotas, Brazil
9: Also at Nanjing Normal University Department of Physics, Nanjing, China
10: Now at The University of Iowa, Iowa City, USA
11: Also at University of Chinese Academy of Sciences, Beijing, China
12: Also at Institute for Theoretical and Experimental Physics named by A.I. Alikhanov of NRC ‘Kurchatov Institute’, Moscow, Russia
13: Also at Joint Institute for Nuclear Research, Dubna, Russia
14: Now at British University in Egypt, Cairo, Egypt
15: Now at Cairo University, Cairo, Egypt
16: Also at Zewail City of Science and Technology, Zewail, Egypt
17: Now at Fayoum University, El-Fayoum, Egypt
18: Also at Purdue University, West Lafayette, USA
19: Also at Université de Haute Alsace, Mulhouse, France
20: Also at Ilia State University, Tbilisi, Georgia
21: Also at Erzincan Binali Yıldırım University, Erzincan, Turkey
22: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
23: Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany
24: Also at University of Hamburg, Hamburg, Germany
25: Also at Department of Physics, Isfahan University of Technology, Isfahan, Iran, Isfahan, Iran
26: Also at Brandenburg University of Technology, Cottbus, Germany
27: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
28: Also at Institute of Physics, University of Debrecen, Debrecen, Hungary, Debrecen, Hungary
29: Also at Physics Department, Faculty of Science, Assiut University, Assiut, Egypt
30: Also at Eszterhazy Karoly University, Karoly Robert Campus, Gyöngyös, Hungary
31: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
32: Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary, Budapest, Hungary
33: Also at Wigner Research Centre for Physics, Budapest, Hungary
34: Also at IIT Bhubaneswar, Bhubaneswar, India, Bhubaneswar, India
35: Also at Institute of Physics, Bhubaneswar, India
36: Also at G.H.G. Khalsa College, Punjab, India
37: Also at Shoolini University, Solan, India
38: Also at University of Hyderabad, Hyderabad, India
39: Also at University of Visva-Bharati, Santiniketan, India
40: Also at Indian Institute of Technology (IIT), Mumbai, India
41: Also at Deutsches Elektronen-Synchrotron, Hamburg, Germany
42: Also at Sharif University of Technology, Tehran, Iran
43: Also at Department of Physics, University of Science and Technology of Mazandaran, Behshahr, Iran
44: Now at INFN Sezione di Bari a, Università di Bari b, Politecnico di Bari c, Bari, Italy
45: Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Bologna, Italy
46: Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy
47: Also at Università di Napoli ‘Federico II’, NAPOLI, Italy
48: Also at Riga Technical University, Riga, Latvia, Riga, Latvia
49: Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico
50: Also at Institute for Nuclear Research, Moscow, Russia
51: Now at National Research Nuclear University ‘Moscow Engineering Physics Institute’ (MEPhI), Moscow, Russia
52: Also at Institute of Nuclear Physics of the Uzbekistan Academy of Sciences, Tashkent, Uzbekistan
53: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
54: Also at University of Florida, Gainesville, USA
55: Also at Imperial College, London, United Kingdom
56: Also at P.N. Lebedev Physical Institute, Moscow, Russia
57: Also at Moscow Institute of Physics and Technology, Moscow, Russia, Moscow, Russia
58: Also at California Institute of Technology, Pasadena, USA
59: Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia
60: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
61: Also at Trincomalee Campus, Eastern University, Sri Lanka, Nilaveli, Sri Lanka
62: Also at INFN Sezione di Pavia a, Università di Pavia b, Pavia, Italy, Pavia, Italy
63: Also at National and Kapodistrian University of Athens, Athens, Greece
64: Also at Universität Zürich, Zurich, Switzerland
65: Also at Ecole Polytechnique Fédérale Lausanne, Lausanne, Switzerland
66: Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria, Vienna, Austria
67: Also at Laboratoire d’Annecy-le-Vieux de Physique des Particules, IN2P3-CNRS, Annecy-le-Vieux, France
68: Also at Şırnak University, Şırnak, Turkey
69: Also at Department of Physics, Tsinghua University, Beijing, China, Beijing, China
70: Also at Near East University, Research Center of Experimental Health Science, Nicosia, Turkey
71: Also at Beykent University, Istanbul, Turkey, Istanbul, Turkey
72: Also at Istanbul Aydin University, Application and Research Center for Advanced Studies (App. & Res. Cent. for Advanced Studies), Istanbul, Turkey
73: Also at Mersin University, Mersin, Turkey
74: Also at Piri Reis University, Istanbul, Turkey
75: Also at Adiyaman University, Adiyaman, Turkey
76: Also at Ozyegin University, Istanbul, Turkey
77: Also at Izmir Institute of Technology, Izmir, Turkey
78: Also at Necmettin Erbakan University, Konya, Turkey
79: Also at Bozok Universitetesi Rektörülüğü, Yozgat, Turkey, Yozgat, Turkey
80: Also at Marmara University, Istanbul, Turkey
81: Also at Milli Savunma University, Istanbul, Turkey
82: Also at Kafkas University, Kars, Turkey
83: Also at Istanbul Bilgi University, Istanbul, Turkey
84: Also at Hacettepe University, Ankara, Turkey
85: Also at Vrije Universiteit Brussel, Brussel, Belgium
86: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
87: Also at IPPP Durham University, Durham, United Kingdom
88: Also at Monash University, Faculty of Science, Clayton, Australia
89: Also at Bethel University, St. Paul, Minneapolis, USA, St. Paul, USA
90: Also at Karamanoğlu Mehmetbey University, Karaman, Turkey
91: Also at Ain Shams University, Cairo, Egypt
92: Also at Bingol University, Bingol, Turkey
93: Also at Georgian Technical University, Tbilisi, Georgia
94: Also at Sinop University, Sinop, Turkey
95: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
96: Also at Texas A&M University at Qatar, Doha, Qatar
97: Also at Kyungpook National University, Daegu, Korea, Daegu, Korea
