Summary.—The effect of adult thymectomy in DBA/2J mice on the in vitro response to syngeneic tumour cells was investigated. Spleen cells from adult mice which had been thymectomized 8 weeks previously demonstrated a severely impaired primary cytotoxic response to P815 tumour cells, whereas their cytotoxic responses to allogeneic cells (C57BL/6) and to non-H-2 antigens (BALB/c), and their ability to form a primary antibody response to sheep red blood cells was unimpaired. Suppressor T cells, specific for P815 cells, appeared early in the thymuses of animals inoculated with P815 cells (between 4 and 8 days after tumour-cell injection). No differences in tumour growth between animals thymectomized as adults and sham-operated controls were observed, and thymectomized tumour-bearing animals had levels of specific suppressor cells in their lymph nodes equivalent to the levels found in untreated controls. Severely thymocyte-deprived animals which had been thymectomized, irradiated and reconstituted with either marrow or spleen cells 8 weeks before tumour implantation succumbed more rapidly to metastatic tumour than did control animals.

The thymus is known to be essential for the differentiation of T lymphocytes during neonatal life, and neonatal thymectomy results in the loss of virtually all the peripheral T lymphocytes, and severe defects in humoral and cellular immunity (Miller and Mitchell, 1969). Recent observations suggest that the thymus, at least in mice, is also involved in various immune responses in adult life. It has been reported that adult thymectomy (ATx) reduces the proportion of a subpopulation of peripheral T lymphocytes which carry a relatively high concentration of the Thy-1 antigen on their surface, preferentially home to spleen rather than lymph nodes in irradiated mice, and are resistant to the in vivo effect of anti-lymphocyte serum (Cantor et al., 1975). It has also been reported that ATx produces the loss of T-dependent mitogen responses in spleen (Jacobs and Byrd, 1975) and a lower secondary humoral response in irradiated recipients of spleen cells from primed adult-thymectomized mice (Simpson and Cantor, 1975). These lower immune responses of ATx animals are thought to be due to a reduced proportion of short-lived T-lymphocyte populations in these animals. These may well constitute the Ly 1,2,3+ population shown by Cantor and Boyse (1975) to be depleted in ATx animals.

In contrast, ATx enhances immune responses in some immunological systems. ATx mice demonstrated higher primary antibody responses against polyvinylpyrrolidone, a thymus-independent antigen, than did sham-thymectomized controls (Kerbel and Eidinger, 1972). Significantly higher primary cytotoxic responses against allogeneic cells by spleen cells from ATx mice have also been reported (Simpson and Cantor, 1975). These observations suggest a possible suppressor effect of thymus cells in adult animals. There is evidence that thymectomy (adult or neonatal) affects immunoregulation, possibly by altering the generation of suppressor cells. When mouse lymphocytes were sensitized against syngeneic fibroblasts in millipore chambers inserted into the peri-
toneal cavity of mice, autosensitization occurred only if the chambers were carried by ATx mice, and this effect could be reversed by the administration of thymic extract (Carnand et al., 1975). Similarly, it has been shown that the thymus is essential for the immunosuppressive state of the graft-vs-host response induced in F1 mice which had been lethally irradiated, reconstituted with neonatal liver cells from parental mice and subsequently challenged with parental spleen cells. Furthermore, the presence of suppressor cells in the thymus has been shown in tolerant animals (Nachtigal, Zan-Bar and Feldman, 1975). Thymocytes from tolerant animals, when transferred to intact animals, specifically suppressed antibody production of recipients (Gershon and Kondo, 1971).

We previously reported that thymocytes, as well as spleen cells, from mice bearing syngeneic P815 mastocytoma suppressed the in vitro generation of specific anti-P815 cytotoxicity mediated by T lymphocytes (Takei, Levy and Kilburn, 1976). Similar suppressive effects of thymocytes have been reported in mice bearing methylcholanthrene-induced sarcomas (Fujimoto, Greene and Sehon, 1976a, b). Unlike many other tumour systems, suppressor cells in P815 tumour-bearing mice were found to be tumour-specific (Takei, Levy and Kilburn, 1977) and had no effect on other immunological functions in the tumour-bearing animal.

The following study was undertaken in an attempt to clarify the effect of ATx on the ability of mice to generate cytotoxic cells specific for the P815 tumour and on the ability of tumour-bearing animals to generate suppressor cells specific for this tumour. The overall effect of ATx on tumour growth was also studied.

MATERIALS AND METHODS

Mice and tumours.—Female DBA/2, BALB/c and C57BL/6 mice (6–10 weeks old) were obtained from the Jackson Laboratory (Bar Harbor, Maine). P815 mastocytoma and L1210 leukaemia were obtained from Dr Bruce Smith (Institute for Cancer Research, Philadelphia, Pa.) and maintained as described previously (Takei et al., 1976, 1977). EL4 leukaemia in C57BL/6 mice was obtained from the Salk Institute for Biological Studies (San Diego, California) and maintained in tissue culture. X63/Ag-8 plasmacytoma in BALB/c was obtained from Dr Terry Pearson (MRC Laboratory of Molecular Biology, Cambridge, England) and maintained in tissue culture. Tumours were implanted in animals by s.c. inoculation of 103, 5 x 103, 104, or 5 x 104 tumour cells taken from ascites tumours and washed in PBS. "Immune" mice whose spleens were used in cytotoxicity assays were killed 12 days after tumour inoculation, when tumours were small and localized.

Cells.—Single-cell suspensions were prepared from spleens, thymuses and lymph nodes by pressing small pieces of tissue through a 60-gauge stainless-steel mesh. The erythrocytes in spleens were lysed with phosphate-buffered 0.85% NH4Cl solution. Cells were subsequently washed twice with PBS containing 5% foetal calf serum (FCS). Viable cells were counted using the trypan-blue-exclusion method.

In vitro generation of cytotoxic cells.—Primary cytotoxicity against P815 or L1210 tumours was generated in vitro as described previously (Takei et al., 1976, 1977) with slight modifications. In short, 107 lymphoid cells from normal DBA/2 mice were incubated with 5 x 105 mitomycin-C-treated tumour cells in tissue-culture bottles (Bijou Bottles, John Scientific, Toronto, Ontario) and the total volume was adjusted to 2-5 ml with RPMI 1640 culture medium (Grand Island Biological Company, Grand Island, New York) containing 10% FCS, 100 μg/ml penicillin, 10 μg/ml streptomycin and 5 x 10–5 M 2-mercaptoethanol. After 5 days cells were harvested, washed with the medium and tested for cytotoxicity.

Cytotoxicity against alloantigens (anti-C57BL/6) was generated by incubating 5 x 106 DBA/2 spleen cells with 2-5 x 106 mitomycin-C-treated C57BL/6 spleen cells in 2 ml of the medium for 4 days. Cytotoxicity against minor histocompatibility antigens (anti-BALB/c) was generated by incubating 5 x 106 DBA/2 spleen cells with 106 mitomycin-C-treated BALB/c spleen cells in 2 ml of the medium for 5 days.
**Cytotoxicity assay.**—Cytotoxicity against P815 and L1210 tumour cells was tested by the $^{51}$Cr-release assay as described previously (Takei et al., 1976, 1977). EL4 cells were used as the target for the anti-C57BL/6 cytotoxicity and X63/Ag-8 plasmacytoma cells for the anti-BALB/c cytotoxicity. The incubation period of the $^{51}$Cr-release assay was 4 h for anti-C57BL/6 and 18–24 h for other cytotoxicity tests. Spontaneous release of P815 cells was 20–25% in 18–24 h, 15–20% for L1210 cells in 18–24 h, 30–35% for X63/Ag-8 in 24 h, and 8–12% for EL4 in 4 h.

**Anti-SRBC antibody-producing cells.**—The in vitro method to generate plaque-forming cells (PFC) against sheep red blood cells (SRBC) has been described elsewhere (Mcmaster and Levy, 1975).

**Suppressor-cell assay.**—The suppressive activity of lymphoid cells from tumour-bearing mouse was tested as described previously (Takei et al., 1976, 1977). Briefly, $5 \times 10^6$ normal spleen cells and $5 \times 10^6$ lymphoid cells to be tested for suppression, or $5 \times 10^6$ control lymphoid cells, were incubated with $5 \times 10^5$ mitomycin-C-treated tumour cells in tissue-culture Bijou bottles and the total volume was adjusted to 2.5 ml with RPMI 1640 culture medium containing $10\%$ FCS, 100 U/ml penicillin, 10 $\mu$g/ml streptomycin, and $5 \times 10^{-5}$m 2-mercaptoethanol. After 4 days, cells were harvested, washed with medium, counted and tested for cytotoxicity by the $^{51}$Cr-release assay as described. The suppressive activity was estimated by the decrease in the cytotoxicity as compared to control cultures in which normal lymphoid cells were used in place of the suppressive lymphoid cells. The degree of suppression was quantitated by the decrease in lytic units, which were calculated from linear-regression analysis of percent cytotoxicity vs logarithm of effector/target cell ratio.

**Thymectomy, irradiation and reconstitution.**—DBA/2 mice were thymectomized at the age of 8–10 weeks (ATx) by the suction method. Age-matched mice were used for the sham-operated animals and untreated controls. Mice were irradiated with 850 rad from a $^{60}$Co source. Four hours after irradiation, animals were reconstituted i.v. with $2 \times 10^7$ marrow or splenic lymphocytes taken from untreated syngeneic donors. Bone marrow cells were taken by washing the marrow from femurs with a syringe and 26-gauge needle into PBS and 5% FCS. Cells for reconstitution were washed, resuspended in PBS and counted before use.

**RESULTS**

**Effect of adult thymectomy on the primary cytotoxic response to syngeneic tumours**

When spleen cells from normal DBA/2 mice were incubated with mitomycin-C-treated P815 tumour or L1210 cells for 5 days as described in the Materials and Methods section, significant cytotoxicity was detected by 24 h incubation of the $^{51}$Cr-release assay. This method was used to study the effects of adult thymectomy on the primary cytotoxic response against syngeneic P815 and L1210 cells.

DBA/2 mice were thymectomized at the age of 8–10 weeks, and left for 2 or 8 weeks. They were subsequently tested for their ability to generate a primary in vitro response to syngeneic tumour cells P815 or L1210. The results are shown in Tables I, II and III. It can be seen that after 2

weeks the response of the ATx animals was the same as for sham-operated controls, whilst the response 8 weeks after ATx was significantly decreased. Therefore, the effects of ATx were dependent on the interval since operation, suggesting that short-lived T cells derived from the adult thymus may be involved in this immune response.

**Effect of ATx on other immune responses.**

In order to test whether the decreased cytotoxic responses to P815 and L1210 cells were unique phenomena or were representative of a general loss of competence, spleen cells from ATx mice were tested for various immune responses. The ATx mice were left for 8 weeks before the tests in all cases.

When spleen cells from ATx mice were tested for the cytotoxic response against allogeneic (C57BL/6) cells in mixed lymphocyte cultures, no significant difference in the cytotoxicity between the ATx and sham-operated STx mice was observed (Table IV).

| Expt | No. animals | ATx | STx | P (Student’st test) |

*Measured as in Table I.

Spleen cells from ATx mice were also tested for the cytotoxic response to minor histocompatibility antigens. For this experiment, DBA/2 spleen cells were sensitized against BALB/c spleen cells, which share the same H-2 genes but differ at the M locus and in minor histocompatibility antigens. The M locus difference is known to induce stimulation of DNA synthesis in mixed lymphocyte cultures, but it does not induce a cytotoxic response (Peck, Alter and Lindahl, 1976). Therefore, the cytotoxicity induced in this experiment is thought to be directed mainly toward minor histocompatibility antigens. As shown in Table V, the cytotoxic response of ATx mice spleen cells was not significantly different from that of STx mice.

| 1    | 4           | 40.9±13.5 25.1±3.9 | >0.05 |
| 2    | 5           | 51.9±4.9 54.9±11.5 | >0.05 |

*Generated by incubating 5×10^6 spleen cells with 10^5 mitomyein-C-treated BALB/c spleen cells for 5 days and then assayed by 51Cr-release, using X63Ag8 tumour cells as targets. Effector: target cell ratio was 40:1; incubation period 24 h.

The effect of ATx on antibody production in vitro was also tested. When spleen cells from ATx and STx mice were incubated with SRBC and then tested for a primary response to SRBC by the PFC assay, no significant difference was observed (Table VI). Therefore, helper function of T lymphocytes seemed not to be impaired by ATx.

**Thymus as a source of suppressor cells**

We had previously shown that DBA/2J mice bearing s.c. inoculated P815 cells

* Spleen cells were sensitized in vitro to sheep erythrocytes.

had in their thymuses and spleens tumour-specific T suppressor cells (Takei et al., 1976; 1977). Because there is some evidence that the thymus itself may be functional in the generation of suppressor cells, a study was undertaken into the appearance of these suppressor cells at various times after tumour implantation. DBA/2 mice were injected s.c. with 5 × 10³ P815 cells. At various times following tumour-cell injection, 3 representative mice were killed and their spleens, thymocytes and lymph-node cells were pooled separately and tested for the presence of suppressor cells. The results are shown in Table VII. It can be seen that significant suppressive activity is first demonstrated in the thymus of tumour-bearing animals. This occurs when tumours are just palpable and some cytotoxicity is apparent in lymph node and spleen cells (Day 8). The finding that suppressor cells are present in the thymus of tumour-bearers 6–8 days after tumour inoculation, and are never present in other lymphoid organs at this time, is a consistent observation with this tumour system.

Because this observation supports the possibility that these suppressor cells might be generated in the thymuses of tumour bearers and subsequently migrate to other lymphoid organs, adult mice were thymectomized and left for 8 weeks, following which the effects of ATx on tumour immunity and tumour growth were studied.

The effect of ATx on tumour growth

ATx mice and STx controls were injected s.c. with 10³, 5 × 10³, 10⁴ or 5 × 10⁴ P815 cells 8 weeks after thymectomy. Since P815 tumours metastasize to the liver, spleen and peritoneal cavity in later stages of tumour growth, the effect of ATx on tumour growth was assessed by 2 criteria; the size of solid tumours measured by caliper, and the survival rate. Although ATx mice showed a slightly slower tumour growth (Fig. 1) and a slightly higher
survival rate (Fig. 2) in the early stages of tumour growth, the differences between the ATx and STx mice were not significant at any time. The results shown here were observed in mice inoculated with $5 \times 10^3$ tumour cells. Results from animals inoculated with either higher or lower tumour-cell numbers were essentially the same as those shown here.

**The effect of ATx on the generation of suppressor cells**

We had already observed that ATx caused a significant decrease in the ability of mouse spleen cells to mount a primary in vitro cytotoxic response to syngeneic tumour cells. However, we also noted that suppressor cells, specific for an antitumour response, appeared to be generated initially in the thymus (Table VII). Experiments were carried out in ATx animals to determine whether suppressor cells were detectable in the lymph nodes of these animals after tumour implantation at times when they are found in intact animals. The results are shown in Table VIII. It can be seen that ATx animals which have had tumour inoculation 8 weeks after surgery develop suppressor cells in their lymph nodes equivalent to those in intact animals (Table VII). It would thus appear that, although these cells appear early in the thymus of tumour-bearing animals, the thymus is not essential for the generation of suppressor cells.

Given that our observations have shown that suppressor cells are still generated in ATx animals, and that the primary in vitro generation of cytotoxic cells to syngeneic tumour cells is reduced but not eliminated in such animals, it is not surprising that the differences in tumour growth between the ATx and STx groups are not statistically significant.

**The effect of severe thymocyte depletion on tumour growth**

While the absence of any differences in tumour growth in between ATx and STx groups can be explained, the question remains whether or not thymocytes in fact play any role in controlling tumour growth, or whether the above observations are fortuitous. In an attempt to answer the question, a further experiment was done. ATx and STx animals were lethally irradiated 2 weeks after surgery and reconstituted with either syngeneic

marrow or spleen cells. After 8 weeks these animals, as well as a group of ATx and STx untreated controls, were challenged with $5 \times 10^3$ P815 cells. The survival times and $t$-test analyses between various groups are shown in Table IX. It can be seen that ATx animals, reconstituted with either marrow or spleen cells, succumbed more rapidly to tumours than did animals in other groups. Postmortem examination showed that death was due to massive metastatic invasion by tumour cells. Also, STx animals reconstituted with marrow fared worse than the comparable group reconstituted with spleen cells.

**DISCUSSION**

The present study clearly showed that adult thymectomy decreased the primary cytotoxic response of spleen cells against syngeneic tumour cells. This was not due to a decrease in general immunological competence of these spleen cells, because their cytotoxic response to allogeneic cells and minor histocompatibility antigens, and their antibody response to SRBC were not affected by ATx. Since this effect was not seen in 2 weeks after ATx, but became apparent 6–8 weeks later, it seems likely that a population of short-lived T lymphocytes which migrate from the thymus to the spleen is involved. Studies of T lymphocytes involved in graft-vs-host responses (Cantor and Asofsky, 1972) and cytotoxic responses to allogeneic cells (Wagner, 1973) have shown a heterogeneity within the T-lymphocyte population. One of the T-lymphocyte subsets (T1) bears a relatively high concentration of the Thy-1 antigen on the cell surface, is found in the thymus and spleen, and is reduced after ATx (Cantor et al., 1975). The other subset (T2), bearing a lower concentration of Thy-1 antigen and being mainly found in lymph nodes, lymph and blood, is not affected by ATx (Cantor et al., 1975).

More recently it has been shown that functionally distinct subsets of T lymphocytes differ in their Ly surface phenotype. In C57BL/6 mice, Ly-2,3 cells generate cytotoxic activity to allogeneic target cells (Cantor and Boyse, 1975; Huber et al., 1976), while cytotoxic T lymphocytes for syngeneic tumour cells are Ly-1,2,3 (Shiku et al., 1976). Moreover, it has been reported that ATx resulted in ≈50% decrease in the proportion of Ly-1,2,3 cells, and a slight increase in the proportion of Ly-2,3 and Ly-1 cells (Cantor and Boyse, 1975). Although it has not been proved that the precursors of cytotoxic cells for syngeneic tumours are also Ly-1,2,3, in the present study antitumour cytotoxicity was generated in vitro using non-immune spleen cells, and the results suggest that the precursors may well be Ly-2,3, and support the possibility that precursors to cytotoxic cells capable of killing syngeneic tumour cells may arise from a subpopulation of T lymphocytes distinct from those capable of generating help or killing allogeneic cells.

The Ly phenotype of suppressor cells, specific for syngeneic tumour cells, is not known, whereas they have been shown to bear the Thy-1 antigen (Takei et al., 1976; Fujimoto et al., 1976a). These suppressor
cells appeared first in the thymuses of tumour-bearing animals. However, our data show that in ATx tumour-bearing animals suppressor cells are present in lymph nodes at levels comparable to those found in intact animals. This indicates that the thymus is not required for the generation of these cells, and that its absence does not affect their formation in any way. ATx in this system appeared to have very little effect on tumour growth and survival time in general.

These essentially negative data might also indicate that thymus-derived cells in fact play no role in tumour immunity, and that observations on suppressor or cytotoxic cells in various situations might be entirely fortuitous. In order to examine this possibility, animals were severely T-cell-depleted by ATx followed by lethal irradiation, and reconstitution with syngeneic marrow cells. Tumour growth in these animals as well as in appropriate controls was followed. It can be seen that in our hands severely thymocyte-deprived animals did less well than other experimental groups, and succumbed more rapidly to metastatic tumour. These observations imply that tumour immunity and temporary tumour containment, at least with this tumour line, is dependent on the presence of an intact immune system. It should be noted that these observations are in direct contrast to work reported by others (Falk, Nossal and Falk, 1977), who found that thymocyte-deprived rats were completely resistant to implantation of a mammary carcinoma. These kinds of contradictory data emphasize the complexity of the relationship of the animal host to its tumour, and imply that no single model can be considered comprehensive.
