Abstract

The vector supersymmetry of the 2D topological $BF$ model is extended to 2D Yang-Mills. The consequences of the corresponding Ward identity on the ultraviolet behavior of the theory are analyzed.
1 Introduction

The relation between the two-dimensional Yang-Mills theory (2DYM) and the topological models has been object of intensive investigations over the past years [1, 2, 3, 4]. In spite of the lacking of local degrees of freedom, 2DYM is nontrivial when analyzed from the point of view of the topological field theories, as underlined for instance by [4] within the BRST framework.

An interesting feature of the topological theories, of both Witten and Schwartz type, is the existence, besides their BRST symmetry, of an additional invariance whose generators carry a vector index. This further symmetry, called vector supersymmetry [5-7], gives rise, together with the BRST generator, to an algebra of the Wess-Zumino type which, closing on-shell on the space-time translations, allows for a supersymmetric interpretation of the topological models [5, 6, 7]. In particular, it has been shown [8] that the existence of the vector supersymmetry is deeply related to the fact that the energy-momentum tensor can be expressed in the form of a pure BRST variation, a key feature which can be taken as the proper definition of the topological theories.

It seems therefore natural to ask ourselves whether this supersymmetric structure can also be found in the 2DYM; this being the goal of the present letter. As one can easily guess, we will be able to show that this question can be actually answered in the affirmative. As a by-product, a simple understanding of the ultraviolet finiteness of 2DYM will be provided.

2 Symmetries of 2DYM

Let us start by considering the gauge invariant Yang-Mills action in 2D euclidean space-time:

\[ S_{YM} = -\frac{1}{4} \int d^2 x \, F^{a \mu \nu} F_{\mu \nu}^a, \]  

(2.1)
where $F^a_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu + g f^{abc} A^b_\mu A^c_\nu$ is the field strength and $g$ stands for the gauge coupling constant. Notice that in 2D the gauge connection is dimensionless, so that the coupling constant $g$ has dimension one.

In order to analyze the symmetries of this model, it is convenient to switch to the first order formalism [4] by rewriting the expression (2.1) in the following form

$$S_{YM} = S_{\text{top}} + S_\phi,$$

where

$$S_{\text{top}} = \frac{1}{2} \int d^2 x \, \varepsilon^{\mu\nu} F^a_{\mu\nu} \phi^a,$$

and

$$S_\phi = \frac{1}{2} \int d^2 x \, \phi^a \phi^a,$$  \hspace{1cm} (2.4)

$\phi^a$ being an auxiliary scalar field. Expression (2.2) is obviously seen to be equivalent to (2.1) upon elimination of the auxiliary field $\phi^a$ through the equations of motion. It is worth remarking here that the use of the first order formalism allows us to interpret to some extent the 2DYM as a deformation of a topological field theory, as it is easily recognized that the term $S_{\text{top}}$ in eq.(2.3) is the action of the two-dimensional topological $BF$ model [9]. The second term $S_\phi$ is metric-dependent, playing therefore the role of the deformation. Expression (2.2) also suggests what will our strategy be in order to establish the vector supersymmetry Ward identity for the 2DYM. To this end we recall that the first term $S_{\text{top}}$ of eq.(2.2), identifying a topological field theory, possesses the vector supersymmetry [9] which, however, will not leave the second term invariant. Nevertheless, it is a remarkable property of the 2DYM that the breaking terms stemming from the non-invariance of the metric-dependent part $S_\phi$ of the action (2.2) can be taken into account by the introduction of a suitable set of external fields. As we shall see, this procedure will enable us to write down an off-shell Ward identity which is an extension of the vector supersymmetry Ward identity of the topological two-dimensional $BF$ model [9]. This identity will strongly constrain the ultraviolet behavior of the 2DYM.

Once established the classical counterpart of the theory, our next step is to get its quantum version. To this aim one has to fix the gauge invariance of the action; we add the following gauge fixing term, by using the Landau
gauge condition:

\[ S_{gf} = \int d^2x \left( b^a \partial^\mu A^a_\mu - \partial^\mu c^a (D_\mu c)^a \right), \]  

(2.5)

where c, \( \overline{c}^a \) and \( b^a \) are the ghost, the anti-ghost and the Lagrange multiplier, respectively. The gauge fixed action

\[ S = S_{YM} + S_{gf} = S_{top} + S_\phi + S_{gf}, \]  

(2.6)

is invariant under the BRST transformations:

\[ sA^a_\mu = - \left( \partial_\mu c^a + g_f^{abc} A^b_\mu c^c \right), \]

\[ sc^a = \frac{1}{2} g_f^{abc} c^b c^c, \]

\[ s\phi^a = g_f^{abc} c^b \phi^c, \]

\[ s\bar{c}^a = b^a, \quad sb^a = 0. \]  

(2.7)

The dimension and the ghost-number of the fields are displayed in Table 1.

| \( A^a_\mu \) | \( \phi^a \) | \( c^a \) | \( \overline{c}^a \) | \( b^a \) |
|---|---|---|---|---|
| Dim | 0 | 1 | 0 | 0 |
| Ng | 0 | 0 | 1 | -1 |

Table 1

Let us now focus on the following sector of the action (2.6):

\[ S_{inv} = S_{top} + S_{gf}, \]  

(2.8)

corresponding to the quantized topological \( BF \) model. As already underlined, besides the BRST invariance (2.7), \( S_{inv} \) has a further symmetry; the so called vector supersymmetry [3], which reads

\[ \delta_\mu A^a_\mu = 0, \]

\[ \delta_\mu \phi^a = - \varepsilon_{\mu\nu} \partial^\nu \overline{c}^a, \]

\[ \delta_\mu c^a = - A^a_\mu, \]

\[ \delta_\mu \bar{c}^a = 0, \]

\[ \delta_\mu b^a = \partial_\mu \overline{c}^a. \]  

(2.9)
In summary, we have
\[ sS_{inv} = 0, \quad \delta \mu S_{inv} = 0. \tag{2.10} \]

In addition, the generators \( s \) and \( \delta \mu \) give rise to the following Wess-Zumino supersymmetric algebra

\[
\{ s, \delta \mu \} \phi^a = \partial \mu \phi^a + \varepsilon_{\mu \nu} \frac{\delta S_{inv}}{\delta A^a_{\nu}}, \tag{2.11}
\]

\[
\{ s, \delta \mu \} A^a_{\nu} = \partial \mu A^a_{\nu} - \varepsilon_{\mu \nu} \frac{\delta S_{inv}}{\delta \phi^a},
\]

\[
\{ s, \delta \mu \} (c, b, \bar{c}) = \partial \mu (c, b, \bar{c}),
\]

which, closing on-shell on the space-time translations, allows for a supersymmetric interpretation of the two-dimensional \( BF \) model.

On the other hand, we can easily verify that, as expected, the metric-dependent term \( S_\phi \) of the quantized 2DYM action in eq.(2.6) breaks the vector supersymmetry invariance (2.9) of the topological sector. In fact

\[
\delta \mu O = -\varepsilon_{\mu \nu} \phi^a \partial^\nu \bar{c}^a, \tag{2.12}
\]

where we have defined \( O = \frac{1}{2} \phi^a \phi^a \). As previously remarked, our procedure in order to control the effects of this breaking is to introduce external fields as follows:

\[
S_\mathcal{O} = \int d^2x \left( \tau \mathcal{O} + \xi^\mu \delta \mu \mathcal{O} + \frac{1}{2} \eta^{\mu \nu} \delta \mu \delta \nu \mathcal{O} + \frac{1}{2} \Omega^{\mu \nu} s \delta \mu \delta \nu \mathcal{O} \right) , \tag{2.13}
\]

with \( \tau \) and \( \xi^\mu \) being respectively scalar and vector external fields, while \( \eta^{\mu \nu} \) and \( \Omega^{\mu \nu} \) are rank-2 anti-symmetric external fields. Their canonical dimensions and ghost-numbers are displayed in Table 2.

|     | s | \( \delta \mu \) | \( \tau \) | \( \xi^\mu \) | \( \eta^{\mu \nu} \) | \( \Omega^{\mu \nu} \) |
|-----|---|----------------|---------|------------|---------------|---------------|
| \( N_g \) | 1 | -1            | 0       | 1          | 2             | 1             |
| \( Dim \)  | 1 | 0             | 0       | 0          | 0             | -1            |

Table 2
It follows thus that the action

\[ S_\tau = S + S_\varnothing , \]

is invariant under the modified nilpotent BRST transformations:

\[ \tilde{s} A^a = - (D_\mu e)^a + \xi^\mu \varepsilon_{\mu \nu} \phi^a , \]

\[ \tilde{s} e^a = \frac{1}{2} g f^{abc} e^b e^c , \]

\[ \tilde{s} \phi^a = g f^{abc} e^b \phi^c , \]

\[ \tilde{s} \varepsilon^a = b_a , \quad \tilde{s} b_a = 0 , \]

\[ \tilde{s} \tau = - \partial_\mu \xi^\mu , \quad \tilde{s} \xi^\mu = 0 , \]

\[ \tilde{s} \Omega_{\mu \nu} = - \eta_{\mu \nu} , \quad \tilde{s} \eta_{\mu \nu} = 0 , \]

\[ \tilde{s} S_\tau = 0 . \]  

Moreover, remarkably in half, \( S_\tau \) turns out to be left invariant by the following extended susy transformations

\[ \tilde{\delta}_\mu e^a = - A^a , \quad \tilde{\delta}_\mu A^a = 0 , \]  

\[ \tilde{\delta}_\mu \phi^a = - \varepsilon_{\mu \nu} \partial_\nu \phi^a , \quad \tilde{\delta}_\mu \phi^a = 0 , \]

\[ \tilde{\delta}_\mu b^a = \partial_\mu \varepsilon^a , \]

\[ \tilde{\delta}_\mu \varepsilon^a = - \delta_{\mu \nu} (1 + \tau ) , \quad \tilde{\delta}_\mu \tau = 0 , \]  

\[ \tilde{\delta}_\mu \eta_{\nu \kappa} = - \delta_{\mu \nu} \xi_\kappa + \delta_{\mu \nu} \xi_\kappa - \partial_\mu \Omega_{\nu \kappa} , \]

\[ \tilde{\delta}_\mu \Omega_{\nu \kappa} = 0 , \]

\[ \tilde{\delta}_\mu S_\tau = 0 , \]

where \( \delta_{\mu \nu} \) is the flat euclidean metric. We see therefore that, as announced, we have been able to account for the breaking generated by the non-topological action \( S_\phi \) by introducing suitable external fields. We are now ready to implement the \( \tilde{s} \) and the \( \tilde{\delta}_\mu \)–invariance of the action \( S_\tau \) as Ward identities. This will be the task of the next section.
3 Ward Identities

Following the standard BRST procedure \cite{10}, we add to expression (2.14) a new term $S_{ext}$, accounting for the nonlinear part of the modified BRST transformations (2.15):

$$S_{ext} = \int d^2 x \left( \gamma^{a\mu} \tilde{s} A^a_\mu + L^a \tilde{s} c^a + \rho^a \tilde{s} \phi^a \right),$$

(3.20)

where the external fields $\gamma^{a\mu}$, $L^a$ and $\rho^a$ have dimensions and ghost-numbers displayed in Table 3.

| Dim | $\gamma^{a\mu}$ | $L^a$ | $\rho^a$ |
|-----|------------------|-------|----------|
| $Ng$ | 1                | 1     | 0        |
|     | $-1$             | $-2$  | $-1$     |

Table 3

Therefore, the complete action

$$\Sigma = S_\tau + S_{ext},$$

(3.21)

obeys the Slavnov-Taylor identity

$$S(\Sigma) = \int d^2 x \left( \frac{\delta \Sigma}{\delta A^a_\mu} \frac{\delta \Sigma}{\delta \gamma^{a\mu}} + \frac{\delta \Sigma}{\delta \phi^a} \frac{\delta \Sigma}{\delta \rho^a} + \frac{\delta \Sigma}{\delta L^a} \frac{\delta \Sigma}{\delta c^a} \right) + b_a \frac{\delta \Sigma}{\delta c^a} - \partial_\mu \xi^a \frac{\delta \Sigma}{\delta \tau} - \frac{1}{2} \eta^{\mu\nu} \frac{\delta \Sigma}{\delta \Omega^{\mu\nu}} = 0.$$

(3.22)

Let us also introduce, for further use, the nilpotent linearized Slavnov-Taylor operator $B_\Sigma$

$$B_\Sigma = \int d^2 x \left( \frac{\delta \Sigma}{\delta A^a_\mu} \frac{\delta}{\delta \gamma^{a\mu}} + \frac{\delta \Sigma}{\delta \gamma^{a\mu} \delta A^a_\mu} + \frac{\delta \Sigma}{\delta \phi^a} \frac{\delta}{\delta \rho^a} + \frac{\delta \Sigma}{\delta \rho^a \delta \phi^a} \right) + \frac{\delta \Sigma}{\delta c^a} \frac{\delta}{\delta L^a} + \frac{\delta \Sigma}{\delta L^a} \frac{\delta c^a}{\delta \Sigma} + b_a \frac{\delta}{\delta c^a} - \partial_\mu \xi^a \frac{\delta}{\delta \tau} - \frac{1}{2} \eta^{\mu\nu} \frac{\delta}{\delta \Omega^{\mu\nu}}),$$

(3.23)

$$B_\Sigma B_\Sigma = 0.$$
Turning now to the vector invariance $\tilde{\delta}_\mu$, it is easily verified that, due to the introduction of the external fields $\gamma_\alpha^\mu$, $L^a$, $\rho^a$, it takes the form of a linearly broken Ward identity, namely

$$W_\mu \Sigma = \Delta^c_\mu,$$

(3.25)

with

$$W_\mu = \int d^2x \left( \varepsilon_\mu^\nu \rho^a \frac{\delta}{\delta A^a_\nu} - A^a_\mu \frac{\delta}{\delta c^a} - \varepsilon_\mu^\nu (\gamma_\alpha^\mu + \partial^\nu e_\alpha^a) \frac{\delta}{\delta \phi^a} - L^a \frac{\delta}{\delta \rho^a} \right.$$

$$+ \partial^\nu c^a \frac{\delta}{\delta b^a} - (1 + \tau) \frac{\delta}{\delta \xi^\mu} + \frac{1}{2} \left( \delta_\mu^\alpha \xi^\beta - \delta_\mu^\beta \xi^\alpha - \partial^\nu \xi^\mu \right) \frac{\delta}{\delta \eta^\alpha^\beta},$$

(3.26)

and

$$\Delta^c_\mu = \int d^2x \left( -\gamma_\alpha^\mu \partial^\nu A^a_\nu + L^a \partial^\nu c^a - \rho^a \partial^\nu \phi^a \right.$$

$$- \varepsilon_\mu^\nu \rho^a \partial^\nu l^a - L^a \xi^\nu \varepsilon_\nu^\mu \phi^a + \gamma_\alpha^\mu \xi^\nu \partial^\nu e_\alpha^a$$

$$- \gamma_\nu^\alpha \xi^\nu \partial^\nu c^a + \gamma_\nu^\alpha \gamma_\mu^\nu e^a \right),$$

(3.27)

We observe that the breaking term $\Delta^c_\mu$, being linear in the quantum fields, is a purely classical breaking and will not get renormalized [10]. It is worth underlining that the final form of the Ward identity (3.25) is the expected one, being indeed a common feature of the topological models, including in particular the associated classical breaking term [6, 7, 8, 9, 11]. We also point out that, in the present case, the complete action $\Sigma$ is constrained by a further linearly broken local Ward identity:

$$F_{\mu \nu}(x) \Sigma = \Delta^F_{\mu \nu}(x),$$

(3.28)

with

$$F_{\mu \nu}(x) = \varepsilon_\nu_\mu \phi^a (x) \frac{\delta}{\delta c^a (x)} + \varepsilon_\nu_\mu L^a (x) \frac{\delta}{\delta \phi^a (x)}$$

$$+ \frac{\delta}{\delta \Omega^{\mu \nu}} (x) + \partial^\nu \frac{\delta}{\delta \xi^\mu (x)} - \partial^\mu \frac{\delta}{\delta \xi^\nu (x)},$$

$$+ (\gamma_\alpha^\mu + \partial^\nu e_\alpha^a) \frac{\delta}{\delta A^{\mu \alpha}} (x) - (\gamma_\alpha^\mu + \partial^\nu c^a) \frac{\delta}{\delta A^{\mu \nu}} ,$$

(3.29)
\[ \Delta F_{\mu\nu}(x) = \gamma^a_\mu \partial_b b^a - \gamma^a_\nu \partial_\mu b^a. \] (3.30)

In particular, the operators \( B_\Sigma, W_\mu \) and \( F_{\mu\nu}(x) \) give rise to a closed algebra given by

\[
\{ B_\Sigma, W_\mu \} = P_\mu + \int d^2 x \xi^\nu F_{\nu\mu}(x), \\
\{ W_\mu, W_\nu \} = \{ W_\mu, F_{\sigma\rho}(x) \} = 0, \\
\{ B_\Sigma, F_{\sigma\rho}(x) \} = \{ F_{\mu\nu}(x), F_{\sigma\rho}(y) \} = 0,
\]

where \( P_\mu \) is the functional operator of the space-time translations, \( i.e. \)

\[ P_\mu = \sum_{\text{All fields } \varphi} \int d^2 x \partial_\mu \varphi \frac{\delta}{\delta \varphi}. \] (3.32)

Finally, let us display the whole set of conditions which are usually imposed in the quantization of Yang-Mills theories in the Landau gauge \([10]\), namely:

- the linearly broken ghost equation Ward identity
  \[ G^a \Sigma = \Delta^a, \] (3.33)
  with
  \[ G^a = \int d^2 x \left( \frac{\delta}{\delta c^a} + g f^{abc} \frac{\delta}{\delta b^c} \right), \] (3.34)
  and
  \[ \Delta^a = \int d^2 x g f^{abc} \left( \gamma^b_\mu A^c_\mu - L^b_\gamma c^c + \rho^b_\gamma \phi^c \right). \] (3.35)

- The gauge fixing condition
  \[ \frac{\delta \Sigma}{\delta b^a} = \partial_\mu A^{a\mu} + \partial_\nu \Omega^{\mu\nu} \partial_\mu c^a. \] (3.36)

- The antighost equation
  \[ \left( \frac{\delta}{\delta c^a} + \partial_\mu \frac{\delta}{\delta c^a} \right) \Sigma = \partial_\nu \eta^{\mu\nu} \partial_\mu c^a + \partial_\nu \Omega^{\mu\nu} \partial_\mu b^a. \]

As we shall see in the next section, the identities (3.22), (3.25) and (3.28) turn out to have far-reaching consequences, accounting for instance for the absence of nontrivial invariant counterterms.
4 Invariant Counterterms

Following the set up of the algebraic renormalization \[10\] and making use of the general results on the cohomology of the Yang-Mills theories \[12\], it is not difficult to establish that the model and its Ward identities are renormalizable. Here, we shall limit ourselves only to state the final result, aiming to provide an algebraic understanding of the finiteness properties of 2DYM. Let us look then at the possible BRST invariant counterterm \( \Sigma_c \) which may affect the ultraviolet behavior of the model. We recall that \( \Sigma_c \) is an integrated local polynomial with dimension bounded by two. Making use of the Ward identities established in the previous section, \( \Sigma_c \) is found to obey the conditions:

\[
\delta \Sigma_c \over \partial b^a = G^a \Sigma_c = 0 \ , \quad (4.37)
\]

\[
\left( \delta \over \partial \bar{c}^a + \partial^\mu \delta \bar{\gamma}_{\mu}^a \right) = 0 \ , \quad (4.38)
\]

\[
\mathcal{B}_\Sigma \Sigma_c = 0 \ , \quad (4.39)
\]

\[
\mathcal{F}_{\mu\nu}(x) \Sigma_c = 0 \ , \quad (4.40)
\]

\[
\mathcal{W}_\mu \Sigma_c = 0 \ . \quad (4.41)
\]

From eq.(4.37) it follows that \( \Sigma_c \) is independent from the Lagrange multiplier \( b^a \) and that it depends only from the differentiated ghost \( \partial^\mu \bar{c}^a \) \[10\]. Moreover, due to the eq.(4.38), the fields \( \bar{c}^a \) and \( \gamma_{\mu}^a \) enter through the combination \[10\]

\[
\hat{\gamma}_{\mu}^a \equiv \gamma_{\mu}^a + \partial^\mu \bar{c}^a \ . \quad (4.42)
\]

Finally, from the conditions (4.39), (4.40) it turns out that the most general BRST invariant counterterm can be written as

\[
\Sigma_c = \Xi + \mathcal{B}_\Sigma \tilde{\Xi} \ , \quad (4.43)
\]

where

\[
\Xi = \eta \int d^2 x \frac{\phi^2}{2} , \quad (4.44)
\]

9
with \( \eta \) being an arbitrary parameter and \( \Xi \) stands for an integrated local polynomial with ghost number -1, representing the trivial part of the cohomology of the operator \( B_\Sigma \). Observe that, due to the eq.(4.40) and to the algebraic relations (3.31), we have 

\[
F_{\mu\nu}(x)B_\Sigma \Xi = B_\Sigma F_{\mu\nu}(x) \Xi = 0 \tag{4.45}
\]

from which it follows that

\[
F_{\mu\nu}(x) \Xi = B_\Sigma \Lambda_{\mu\nu}(x) \tag{4.46}
\]

for some local polynomial \( \Lambda_{\mu\nu}(x) \) of ghost number -3. We are left thus with a unique nontrivial BRST invariant counterterm given by eq.(4.44). Expression (4.44) is physically equivalent to the standard Yang-Mills counter term \( \int d^2 x F^a_{\mu\nu} F^a_{\mu\nu} \). This statement relies on the observation that the auxiliary field \( \phi^a \) has in fact the role of \( \varepsilon^{\mu\nu} F^a_{\mu\nu} \), as it is implied by the equations of motion. Also, it should be observed that the coefficient \( \eta \) in eq.(4.44) has the meaning of a possible ultraviolet renormalization of the gauge coupling constant \( g \) compatible with the BRST invariance.

It remains now to impose the final constraint (4.41). Making use of the algebraic relations (3.31), it follows that

\[
W_\mu B_\Sigma \Xi = -B_\Sigma W_\mu \Xi + \{B_\Sigma, W_\mu\} \Xi = -B_\Sigma \left(W_\mu \Xi + \int d^2 x \xi^\nu F_{\nu\mu} \Xi\right)\tag{4.47}
\]

where use has been made of eq.(4.46) and of the fact that \( B_\Sigma \xi_\mu = 0 \). Therefore, from the requirement of invariance under the Ward operator \( W_\mu \), we have

\[
W_\mu \Sigma_c = W_\mu \Xi - B_\Sigma \left(W_\mu \Xi + \int d^2 x \xi^\nu \Lambda_{\nu\mu}\right) = 0 \tag{4.48}
\]

i.e.

\[
- \eta \int d^2 x \varepsilon_{\mu\nu} \hat{\gamma}^{\alpha\nu} \phi^a = B_\Sigma \left(W_\mu \Xi + \int d^2 x \xi^\nu \Lambda_{\nu\mu}\right) \tag{4.49}
\]

implying that \( \int d^2 x \varepsilon_{\mu\nu} \hat{\gamma}^{\alpha\nu} \phi^a \) is a trivial element of the integrated cohomology of \( B_\Sigma \). However, it can be shown that this term cannot be actually cast in
the form of a pure $B_\Sigma$–variation, as it identifies a nontrivial element of the integrated cohomology of $B_\Sigma$, namely

$$\int d^2 x \, \varepsilon_{\mu\nu} \gamma^{\mu\nu} \phi^a \neq B_\Sigma – \text{variation} . \quad (4.50)$$

The only way out is thus

$$\eta = 0 , \quad (4.51)$$

meaning that there is no nontrivial BRST invariant counterterm compatible with the vector Ward identity (3.25), providing therefore a simple algebraic understanding of the well known ultraviolet finiteness properties of 2DYM$^1$. It is useful remarking that the algebraic proof of the absence of nontrivial counterterms given here follows exactly the same lines of the proofs of the ultraviolet finiteness of the topological models $[3, 6, 7, 8, 11]$, emphasizing in particular the pivotal role of the vector Ward identity (3.25).
