**ABSTRACT**

Nuts and seeds are good sources of oil. Most of these oil are edible and are of industrial use. In term of edibility, some seed oils are hyperlipidemic, while some are hypolipidemic. The *Hura crepitans* (sandbox tree) is one of the plants that bear seeds however, the seeds has not been fully utilized. This study investigated the effects of *Hura crepitans* seed oil on lipidomics of some tissues (blood, liver, heart, kidney and brain) in albino rats. The *Hura crepitans* seed oil (HCSO) was extracted with Soxhlet extractor using petroleum ether as solvent. Twenty-four male albino rats allocated to four groups of 6 rats each were used. Groups 1-3 were fed diet containing 5 %, 10 % and 15 % HCSO respectively while group 4 was fed diet containing 15% groundnut oil (GO) (control) for 8 weeks. Whole blood was collected and the tissues (liver, heart, brain and kidney) were harvested. Cholesterol, triacylglycerol and phospholipid levels were determined in plasma, RBC and tissues of the rats spectrophotometrically. Hepatic HMG-CoA reductase activity was indirectly determined using spectrophotometric method. One-way analysis of variance (ANOVA) and Tukey’s test were used to analyse the results. The lipids analyses showed that HDL and VLDL cholesterol levels decreased significant (p < 0.05) in the 5 % and 15 % HCSO groups and in plasma, liver and kidney of 10% HCSO group. Also a significantly ( p< 0.05) increase was observed in RBC cholesterol level in 5 % and 15 % HCSO groups while cardiac cholesterol level increased significantly in 10 % HCSO group. Triacylglycerol level increased significantly in plasma, VLDL and liver (5 % and 10% HCSO group), kidney and brain (5 % HCSO group), RBC and heart (15 % HCSO group) while a decrease ensued in HDL across the groups. The phospholipids level decreased significantly in all the organs except kidney of 15 % HCSO group whereas an increase was observed in plasma, HDL, VLDL and RBC of all the groups. *Hura crepitans* seed oil is considerably hypolipidemic and could be edible and be beneficial to health especially at 10 % composition.

Key word: *Hura crepitans*; seed oil; Edibility; Lipids.
INTRODUCTION
Edible oils are gotten from seeds of some plants and animal fats. They are good sources of energy and nutrients serving as main constituent of various diets, especially essential fatty acids (Odeomelam, 2005; Akubugwo et al., 2008).

A good number of seed oils have been characterized. Attention has been shifted to evaluations of non-utilized oil seeds for possible edible use (Fowomola and Akindahunsi, 2007). The *Hura crepitans* (sandbox tree) is one of the seed-bearing plants that has not been fully evaluated, and there is a need to seek for more seed oils that will be beneficial to humans.

*H. crepitans* (Sandbox tree) is an evergreen tree of Euphobiaceae family that is freely available in Nigeria but has not been fully-utilized. It is recognized by many dark pointed spines that covers the bark and its large heart shaped leaves with prominent secondary veins.

The oil content for *Hura crepitans* ranges from 37.78% to 53.61% (w/w) (Oderinde et al., 2009; Okolie et al., 2012). Which make it suitable for industrial application (WHO, 1993). The crude protein ranges from 24.76 to 37.64 and crude fiber between 1.21 to 10.15 ± 0.03 (Oyeleke et al., 2012; Muhammed et al., 2013). Alabi et al. (2013) reported that the saponifiable matter of *H. crepitans* seed oil contains different fatty acids. Linoleic acid was found as major (36.6%) followed by oleic acid (26.9%) and palmitic acid (21.7%). Moderate amount of stearic acid (9.7%) and arachidic acid (2.5%) was found. Myristic acid, palmitoleic acid, margaric acid, linolenic acid, behenic acid and lignoceric acid were found in very low quantity; (0.2%), (0.6%), (0.3%), (0.8%), (0.3%) and (0.5%) respectively. 35.2% and 64.9% were the total saturated and total unsaturated respectively.

Okolie et al. (2012) reported that the proportions of unsaturated and saturated fatty acids of *H. crepitans* seed oil was 66.483% and 8.994% respectively. *H. crepitans* seed oil is reported to have long shelf-life since the moisture content of *H. crepitans* seed oil is 3.0 % (Oderinde et al., 2009).

In Nigeria, the major sources of edible oil are groundnut also called peanut (*Arachis hypogaea L.*) and oil palm (*Elaeis guineensis*). These oils are used mainly as cooking oil and for the production of soap, margarine, and cosmetics (Ong et al., 1995). Vegetable oil had made an important contribution to the diet in many countries, serving as a good source of protein, lipid and fatty acids for human nutrition including the repair of worn out tissues, new cells formation as well as a useful source of energy (Gaydou et al., 1983; Grosso and Guzman, 1995; Grosso et al., 1997, 1999). Oil quality and its stability are therefore very important for the consumers and application industries (Jambunathan et al., 1993).

Findings have demonstrated that diets high in groundnut oil are as effective as olive oil in preventing heart disease and are heart healthy than very low fat diets (Ugbaja et al., 2015). Hence, this study sought to investigate and compare the effects of *H. crepitans* seed oil and groundnut oil as edible oil in diet on lipidomics of rat tissues.
MATERIALS AND METHODS

Animals and Experimental Design: Twenty four male albino rats, were obtained from a reputable animal farm. They were maintained under standard conditions of humidity (40-60%), temperature (20 – 22 °C), and 12 hours light and 12 hours darkness cycle. They were acclimatized to housing conditions for two weeks prior to the commencement of the study. Their feeds as shown in table 1 were compounded with *Hura crepitans* seed oil and ground nut oil. The diets were fed to the rat for 8 weeks with fresh water *ad libitum*. The composition of feed is shown in Table 2.

Blood collection and isolation of organs

At the end of administration, the rats were sacrificed by anesthesia using diethyl ether. Blood was collected by cardiac puncture into Lithium-heparinized sample bottles. The whole blood samples was centrifuged immediately at 3000rpm for 15minutes to separate plasma from red blood cells. The organs needed were harvested and kept in ice cold condition for further analysis, while the RBC were washed thrice with ice-cold physiological saline solution before using for analysis.

Table 1: Experimental design

| Group            | No of Albino rats | Proportion of oil in compounded feed                  |
|------------------|-------------------|-------------------------------------------------------|
| Group 1 (control)| 6                 | Ground nut oil (GO) (15%)                             |
| Group 2          | 6                 | *Hura crepitans* seed oil (HCSO) (15%)                |
| Group 3          | 6                 | HCSO (10%) + GO (5%)                                  |
| Group 4          | 6                 | HCSO (5%) + GO (10%)                                  |
Table 2: Composition of diet

| Composition                     | Normal diet g/100g | 15% oil diet g/100g | 10% oil diet g/100g | 5% oil diet g/100g |
|--------------------------------|--------------------|---------------------|---------------------|-------------------|
| Maize                          | 40                 | 40                  | 40                  | 40                |
| Flour binder                   | 10                 | 10                  | 10                  | 10                |
| Soy Bean                       | 7                  | 7                   | 7                   | 7                 |

**Biochemical Analyses:**

Plasma concentrations of cholesterol and triacylglycerol were determined using the Cypress diagnostic kits. Plasma phospholipid was determined according to the method of Stewart (1979). HDL-cholesterol and triacylglycerol were determined in plasma with the same diagnostic kits after very low density lipoproteins and low density lipoproteins (VLDL-LDL) were precipitated using the method described by Gidez *et al.* (1982). HDL-phospholipids was determined according to the method of Stewart (1979).

RBC lipids were extracted using chloroform-isopropanol (7:11, v/v) described by Rose and Oklander (1965). For cholesterol determination, 0.1 ml of the extract was evaporated to dryness at 60°C and 20μl of Triton X-100/chloroform mixture (1:1, v/v) was added to the dried extract and evaporated again.

Cholesterol kit reagent (1.0 ml) was added, mixed and incubated for 30 minutes before reading the absorbance in a spectrophotometer. Triacylglycerol concentration was determined by evaporating to dryness 0.1ml of the extract and adding 0.1 ml of 97% ethanol to re-suspend the dried lipid. To
this, 1 ml of the triacylglycerol kit reagent was added, mixed and incubated for 30 minutes before the absorbance reading was taken.

RBC lipid extract (0.1ml) was pipetted into Eppendorf tube and evaporated to dryness over boiling water. To the extract was added 2 ml chloroform and 2 ml ammonium ferrothiocyanate and thoroughly mixed. The chloroform layer was carefully removed using Pasteur’s pipette. The absorbance was read at 488nm as described in determination of plasma phospholipids.

For the organ lipid profiles, lipids were extracted from brain, heart, kidney and liver as described by Folch et al. (1957). Homogenate of the organs (10%) was prepared in chloroform-methanol (2:1) mixture. The homogenates were then spun at 4000 rpm for 10 minutes in a centrifuge and the supernatants containing the lipids were removed into clean Eppendorf tubes. After washing with 0.05M KCl, 0.1 ml each of the chloroform-methanol extract were used for the determination of cholesterol, triacylglycerol and phospholipids after being evaporated to dryness at 60°C. The lipid profiles were determined in aliquots of the extracts as described for RBC above.

**Determination of HMG-CoA reductase activity**

The activity of 3-hydroxy-3-methyl-glutaryl-CoA (HMG CoA) reductase in the liver was determined indirectly using the method described by Rao and Ramakrishnan (1975) by estimating the ratio of HMG CoA: mevalonic acid as an index of enzymatic activity. Liver homogenate (10% w/v) was prepared in saline arsenate solution (lg/L). Equal volumes of fresh 10% (w/v) liver homogenate and dilute Perchloric acid (50ml/L) were mixed, allowed to stand for 5 minutes and centrifuged at 2000 rpm for 10 minutes. Then 1 ml of the filtrate was treated with 0.5ml of freshly prepared hydroxylamine reagent (alkaline hydroxylamine in the case of HMG CoA and neutral hydroxylamine in the case of mevalonate), mixed and after 5 minutes, 1.5ml of ferric chloride reagent was added and shaken. The absorbance was read after 10 minutes at 540nm versus a similarly treated saline/arsenate blank.

**Statistical analysis:**

Results are expressed as mean ± S.E.M. One way analysis of variance (ANOVA) followed by Tukey’s Test was used to analyze the results with p < 0.05 considered significant.

**Results**

Table 3: Effects of *H. crepitans* seed oil and groundnut oil on plasma, HDL, LDL, VLDL and RBC cholesterol levels (mg/dL)
Values are expressed as mean ± SEM (n = 5).
Values with different superscripts in the same column are significantly different (p < 0.05).

Table 4: Effects of *H. crepitans* sees oil and groundnut oil on plasma, HDL, LDL-VLDL and RBC triacylglycerol level (mg/dL)

|                     | Baseline | 5 % HCSO   | 10 % HCSO   | 15 % HCSO   | 15 % GO    |
|---------------------|----------|------------|-------------|-------------|------------|
| Plasma triacylglycerol | 76.41 ± 1.62<sup>a</sup> | 110.44 ± 1.13<sup>b</sup> | 99.60 ± 4.09<sup>b</sup> | 115.16 ± 1.6<sup>c</sup> | 87.76 ± 1.19<sup>a</sup> |
| HDL triacylglycerol   | 10.18 ± 0.31<sup>a</sup> | 12.65 ± 0.87<sup>a</sup> | 41.73 ± 1.01<sup>b</sup> | 70.68 ± 0.61<sup>d</sup> | 46.81 ± 0.85<sup>c</sup> |
| VLDL-LDL triacylglycerol | 4.98 ± 0.00<sup>b</sup> | 5.60 ± 0.16<sup>b</sup> | 5.10 ± 0.12<sup>b</sup> | 3.01 ± 0.37<sup>a</sup> | 2.08 ± 0.26<sup>a</sup> |
| RBC triacylglycerol   | 9.32 ± 0.44<sup>a</sup> | 13.02 ± 0.15<sup>c</sup> | 11.81 ± 0.16<sup>b</sup> | 16.43 ± 0.26<sup>d</sup> | 13.50 ± 0.05<sup>c</sup> |

Values are expressed as mean ± SEM (n = 5).
Values with different superscripts in the same column are significantly different (p < 0.05).

Table 3 shows the cholesterol level in the plasma, HDL, LDL, VLDL-LDL and RBC of animals fed HCSO and GO compounded diets. The plasma cholesterol level of the 10 % *H. crepitans* group was significantly reduced (p < 0.05) compared to the levels obtained for the other
HCSO groups and 15% groundnut oil. There was no significant (p > 0.05) difference between 15% groundnut oil and the other groups.

The HDL-cholesterol level of 10% H. crepitans and 15% groundnut oil groups were significantly (p < 0.05) higher compared to the other groups. The same was observed for VLDL-cholesterol level.

VLDL-cholesterol of 10% HCSO and 15% groundnut oil groups were significantly (p < 0.05) higher compared to other groups, the least VLDL-cholesterol was observed in the 15% Hura crepitans groups. The group fed the 10% Hura crepitans diet had the least LDL-cholesterol and was significantly (p < 0.05) different from the other groups. There was no significant difference between the 10% HCSO and 15% groundnut oil in red blood cells cholesterol. 5% and 15% HCSO had a significantly (p < 0.05) higher red blood cells cholesterol compared to other groups.

In Table 4, the effects of H. crepitans seed oil and groundnut oil on plasma, HDL, and LDL-VLDL triacylglycerol is presented. There was significant (p < 0.05) increase in plasma triacylglycerol level of the 5% and 15% HCSO groups compared to 15% GO fed group. The 15% HCSO group exhibited significantly (p < 0.05) higher HDL triacylglycerol level compared to 15% groundnut.

There was no significant difference (p > 0.05) between the 5% HCSO and 10% HCSO groups with higher VLDL-LDL triacylglycerol, also there was no significant difference between the 15% HCSO and 15% GO groups with lower VLDL-LDL triacylglycerol. On the other hand 15% HCSO group had significantly (p<0.05) higher RBC triacylglycerol level compared to 15% groundnut group while 10% HCSO had a significantly (p < 0.05) lower RBC triacylglycerol level compared to 15% groundnut oil. There was no significant difference (p > 0.05) between 5% HCSO and 15% HCSO groups.

Table 5: Effects of H. crepitans seed oil and groundnut oil on plasma, HDL, VLDL-LDL and RBC phospholipids (mg/dL)

|                      | Baseline | 5% HCSO | 10% HCSO | 15% HCSO | 15% GO  |
|----------------------|----------|---------|----------|----------|---------|
| Plasma phospholipid  | 22.48 ± 0.12<sup>a</sup> | 41.80 ± 0.17<sup>c</sup> | 31.12 ± 1.42<sup>b</sup> | 53.66 ± 1.83<sup>d</sup> | 28.14 ± 0.99<sup>b</sup> |
| HDL phospholipid     | 22.30 ± 0.00<sup>a</sup> | 29.48 ± 0.35<sup>c</sup> | 34.78 ± 0.28<sup>d</sup> | 34.83 ± 0.57<sup>d</sup> | 26.12 ± 0.53<sup>b</sup> |
| VLDL-LDL phospholipid| 22.18 ± 0.00<sup>a</sup> | 21.94 ± 0.09<sup>b</sup> | 23.60 ± 0.19<sup>c</sup> | 20.81 ± 0.12<sup>a</sup> | 20.44 ± 0.07<sup>a</sup> |
| RBC phospholipid     | 13.36 ± 0.97<sup>b</sup> | 14.36 ± 0.60<sup>b</sup> | 15.26 ± 0.31<sup>b</sup> | 18.63 ± 0.95<sup>c</sup> | 10.93 ± 0.22<sup>a</sup> |

Values are expressed as mean ± SEM (n = 5).

Values with different superscripts in the same column are significantly different (p < 0.05).
Table 5 shows there was no significant difference (p > 0.05) in the plasma phospholipid level between the 10% HCSO and 15% GO groups. 5% HCSO and 15% HCSO had significantly (p < 0.05) increased plasma phospholipid level compared to other groups. 10% and 15% HCSO exhibited a significantly (p < 0.05) higher HDL phospholipid compared to other groups. On the other hand, 10% HCSO had the highest level of VLDL-LDL phospholipid and it was significant (p < 0.05) difference compared to other groups. All the groups had significantly (p < 0.05) higher RBC phospholipid level compared to 15% groundnut group.

Table 6: Effects of *H. crepitans* seed oil and groundnut oil on liver, heart, Kidney and brain cholesterol levels (mg/dL)

|                | Baseline  | 5% HCSO | 10% HCSO | 15% HCSO | 15% GO  |
|----------------|-----------|---------|----------|----------|---------|
| Liver cholesterol | 2.22 ± 0.389<sup>a</sup>  | 15.81 ± 0.29<sup>d</sup> | 8.20 ± 0.29<sup>b</sup> | 12.44 ± 0.34<sup>c</sup> | 12.79 ± 0.38<sup>c</sup> |
| Heart cholesterol   | 2.09 ± 0.24<sup>b</sup>  | 1.77 ± 0.14<sup>a</sup>  | 1.92 ± 0.59<sup>b</sup> | 1.67 ± 0.32<sup>a</sup>  | 1.71 ± 0.103<sup>a</sup> |
| Kidney cholesterol   | 12.25 ± 0.03<sup>a</sup> | 18.65 ± 0.24<sup>c</sup> | 15.98 ± 0.26<sup>b</sup> | 18.80 ± 0.20<sup>c</sup> | 19.31 ± 0.12<sup>c</sup> |
| Brain cholesterol    | 9.88 ± 0.03<sup>a</sup>  | 17.81 ± 0.05<sup>b</sup> | 17.69 ± 0.18<sup>b</sup> | 18.34 ± 0.09<sup>b</sup> | 18.35 ± 0.17<sup>b</sup> |

Values are expressed as mean ± SEM (n = 5). Values with different superscripts in the same column are significantly different (p < 0.05).

Table 6 is the summary of the effect of *H. crepitans* seed oil and groundnut oil on liver, heart, Kidney and brain cholesterol levels. There was no significant difference (p > 0.05) between the 15% HCSO and the 15% GO group hepatic cholesterol level. The hepatic cholesterol level of 5% HCSO was significantly (p < 0.05) high compared to 15% GO group, while the 10% HCSO had a lower hepatic cholesterol level compared to the 15% GO. In cardiac cholesterol, there was no significant difference in all the groups except for 10% HCSO with a significantly (p < 0.05) increased cardiac cholesterol level compared to the 15% HCSO. No significant difference (p > 0.05) in kidney cholesterol concentration in all the groups except for 10% HCSO group which was significantly (p < 0.05) decreased. Also, no significant different in the concentration of brain cholesterol in all the groups as shown.
Table 7: Effects of \textit{H. crepitans} seed oil and groundnut oil on liver, heart, Kidney and brain triglycerol levels (mg/dL)

|                  | Baseline  | 5 % HCSO | 10 % HCSO | 15 % HCSO | 15 % GO |
|------------------|-----------|----------|-----------|-----------|---------|
| **Liver** triacylglycerol | 4.64 ± 0.11\textsuperscript{a} | 8.58 ± 0.22\textsuperscript{c} | 8.56 ± 0.04\textsuperscript{c} | 4.62 ± 0.10\textsuperscript{a} | 6.82 ± 0.17\textsuperscript{b} |
| **Heart** triacylglycerol    | 8.90 ± 0.08\textsuperscript{a} | 13.92 ± 0.04\textsuperscript{b} | 16.39 ± 0.07\textsuperscript{c} | 18.58 ± 0.26\textsuperscript{d} | 12.21 ± 0.16\textsuperscript{b} |
| **Kidney** triacylglycerol   | 21.87 ± 0.00\textsuperscript{d} | 19.87 ± 0.06\textsuperscript{c} | 13.51 ± 0.15\textsuperscript{a} | 15.53 ± 0.11\textsuperscript{b} | 15.03 ± 0.33\textsuperscript{b} |
| **Brain** triacylglycerol    | 12.42 ± 0.06\textsuperscript{d} | 10.91 ± 0.18\textsuperscript{c} | 8.23 ± 0.05\textsuperscript{a} | 9.89 ± 0.05\textsuperscript{b} | 9.96 ± 0.04\textsuperscript{b} |

Table 7 present the summary of the effect of \textit{H. crepitans} seed oil and groundnut oil on liver, heart, Kidney and brain triacylglycerol levels. There was a significant (p < 0.05) increase in the hepatic triacylglycerol of the 5 % and 10 % HCSO groups compared to the 15 % groundnut oil group, while the 15 % HCSO had a significantly (p < 0.05) decreased hepatic triacylglycerol level compared to the 15 % HCSO.

There was a significantly (p < 0.05) increased cardiac triacylglycerol level in the 5 % and 10 % HCSO groups compared to 15 % groundnut oil group.

10 % HCSO had a significantly (p < 0.05) reduced kidney triacylglycerol concentration compared to the 15 % GO group while 5 % HCSO had a significant (p < 0.05) increased kidney level compared to the 15 % GO.

On the other hand there was a significant (p < 0.05) decreased in the 10 % HCSO brain triacylglycerol level compared to the 15 % groundnut.
Table 8: Effects of *H. crepitans* seed oil and groundnut oil on liver, heart, Kidney and brain phospholipid levels (mg/dL)

|                  | Baseline   | 5 % HCSO   | 10 % HCSO  | 15 % HCSO  | 15 % GO    |
|------------------|------------|------------|------------|------------|------------|
| Liver phospholipid | 40.09 ± 0.24^d | 31.79 ± 0.15^c | 19.93 ± 0.59^b | 10.77 ± 0.32^a | 41.71 ± 0.10^d |
| Heart phospholipid | 9.44 ± 0.02^a  | 13.67 ± 0.31^b  | 12.77 ± 0.07^b  | 15.17 ± 0.47^c  | 14.53 ± 0.04^c  |
| Kidney phospholipid | 13.45 ± 0.03^a  | 20.20 ± 0.85^c  | 17.29 ± 0.19^b  | 24.71 ± 0.23^d  | 21.22 ± 0.16^c  |
| Brain phospholipid | 20.40 ± 1.00^a  | 21.89 ± 0.19^a  | 21.75 ± 0.27^a  | 21.91 ± 0.12^a  | 20.94 ± 0.43^a  |

Table 8 is the summary of the effect of *H. crepitans* seed oil and groundnut oil on liver, heart, Kidney and brain phospholipid levels. There were significant (p < 0.05) decrease in hepatic phospholipid level in all the groups compared to the 15% GO. There was no significant difference between the 15% HCSO and 15% GO group cardiac phospholipid level, meanwhile 5% and 10% HCSO had a significantly (p<0.05) decreased cardiac phospholipid level compared to the 15% GO. 10% HCSO had a significantly reduced kidney phospholipid when compared to 15% GO group. There was no significant difference in the concentration of the brain phospholipid in all the groups.

Figure 1 explains the effects of the oil on the ratio of HMG-CoA/Mevalonate. The ratio of HMG-CoA to Mevalonate in the liver is inversely proportional to the activity of the enzyme, HMG-CoA reductase. The activity of the enzyme in the 5% HCSO, 15% HCSO and 15% groundnut oil was significantly (p < 0.05) higher than that of 10% HCSO.
Figure 1: Effects of *H. crepitans* seed oil and groundnut oil on ratio of HMG CoA to mevalonate in the liver

Bars are mean ± SEM
Bars with different superscripts in the same column are significantly different (p < 0.05).
DISCUSSION

Lipids are considered one of the most elemental nutrients for humans. Lipid metabolism generates many bioactive lipid molecules, which are fundamental mediators of multiple signaling pathways and they are also indispensable compounds of cell membranes. Any kind of changes in lipid metabolism can result in modification of membrane composition and subsequently in changes in its permeability (Brenna, 2002; Burdge and Calder, 2005).

From the study, it is indicated that inclusion of both *H. crepitans* seed oil and groundnut oil at different percentage in the diet elicited different degree of tissue dyslipidemia. The dyslipidemia was shown by down-regulation and up-regulation of different lipids by the oils in various compartments.

It is a known fact that dietary oil intake plays a role in nutrition and health (Romon *et al*., 1995; Celebi and Utlu, 2006; Arterburn *et al*., 2008; Ighosotu and Tonukari, 2010; Ugbaja *et al*., 2015). They have an impact on total body fat composition and by extension metabolism of lipids (Oluba *et al*., 2011). In table 3, compared to the 15% GO (control) group, the dyslipidemia was characterized by hypocholesterolemia in 10% HCSO while there was no significant different between the control and the remaining group, whereas there was significant increase in the plasma triacylglycerol of both 15% and 10% HCSO group compared to 15% GO. Ugbaja *et al*., 2015 reported that groundnut oils effected a decrease in the level of cholesterol and triacylglycerol in the plasma, which implies that groundnut oil is beneficial in nutrition and health. In this study, there is no significant different between the 15% GO and 15% HCSO plasma cholesterol this implies that HCSO could also be beneficial in nutrition and health in lowering plasma cholesterol and triacylglycerol, and could even bring the cholesterol to a lower level at 10% HCSO concentration. Also, there was no significant different between the control and 10% HCSO in the HDL cholesterol, whereas a decrease ensue in other groups compared to the 15% GO HDL-cho meanwhile in HDL triacylglycerol there was an increase in the 15% HCSO while other groups has a lower concentration compared to the 15% GO.

HDL is the smallest and densest of the lipoproteins, containing the highest proportion of protein to cholesterol. In a normal healthy individual, HDL carries about 20-30% of total plasma cholesterol, whereas LDL (low density lipoprotein or bad cholesterol) carries about 70%. HDL is important for the synthesis of steroid hormones but it is more famously known for its protective role against cardiovascular disease. Reverse cholesterol transport is the method by which HDL removes excess cholesterol from tissues and arteries, and returns it back to the liver for recycling and excretion, interrupting the process of atherosclerosis (narrowing of the arteries) at key stages. Its protective properties include anti-inflammatory activity, where it protects artery walls against LDL plus an anti-oxidative activity, which in combination, may directly slow atherosclerosis (Sanossian *et al*., 2007).
From the result of this findings, the high HDL cholesterol observed in the 10 % HCSO could be as a result of the mixture of the two oil in the ratio 2:1 as the oils are rich in unsaturated fat, Groundnut oil as well as *Hura crepitans* oil are rich in unsaturated fatty acids. Groundnut oil is rich in oleic acid which increases HDL-cholesterol. (Ugbaja et al., 2015) On the other hand, saturated fat intake increases LDL-cholesterol and decreases HDL-cholesterol (Mensink and Katan, 1992). The 10 % HCSO has the highest value of HDL-cholesterol and lowest value of LDL-cholesterol when compared with the control. *Hura crepitans* oil could be effectively in lowering blood cholesterol, primarily LDL-cholesterol as it contains a good proportion of linoleic acid which favours the synthesis of LDL receptors on the liver and other tissue cells that will take up LDL and increase the process of reverse cholesterol transport especially from the heart to the liver for catabolism (Cedomila et al., 2001; Murray et al., 2003).

Cholesterol was significantly decreased in plasma by 10% HCSO, while cholesterol was significantly increase in HDL compartment of the 10% HCSO. This could be due to the combination of HCSO and GO in the ratio 2:1. Since groundnut oil is said to contain squalene (Azalia et al., 2018). Miettinen and Vanhanen (1994), reported that Chronic intake of squalene, mimicking a diet rich in squalene, led to increased cholesterol precursor sterols and raised cholesterol concentrations, but a smaller dose of squalene normalized the situation. The decrease cholesterol in plasma, liver and kidney in 10% HCSO could be attributed to the little amount of squalene in the diet. Little amount of squalene consumption has been found even to reduce serum cholesterol (Chan et al., 1996). The reduction in the level of cholesterol observed in this could be as a result of the long term intake of squalene though in a lesser amount in the case of 10% HCSO. Possible compensatory mechanisms to prevent the increase of serum cholesterol during a moderate long-term squalene consumption are reduced HMG-CoA reductase activity and increased fecal elimination of cholesterol as cholesterol itself and bile acids (Strandberg et al., 1990). There is, however, a conflict considering the lack of association between high squalene intake and coronary artery disease in Mediterranean populations consuming lots of olive oil (Keys et al., 1986). Daily doses that elevate serum cholesterol levels, i.e. 1 g/day, can be reached in individuals consuming large amounts (100 g/day) of olive oil. On the other hand, squalene has been reported to exhibit cellular radioprotective effects probably due to antioxidant properties (Storm et al., 1993). However, animal experiments have indicated that squalene feeding increases tissue squalene and cholesterol contents (Liu et al., 1975; Tilvis and Miettinen, 1983) reflecting stimulated cholesterol production from squalene. Labeled squalene administered to rats is converted to methyl sterols and rapidly to cholesterol mainly in the liver, with only trace amounts in the fat tissue (Miettinen and Vanhanen, 1994).

HDL enables lipids like cholesterol and triglycerides to be transported within the water-based bloodstream. In healthy individuals, about thirty percent of blood cholesterol is carried by HDL. Blood tests typically report HDL-C level, i.e. the amount of cholesterol contained in HDL particles. It is often contrasted with low density or LDL cholesterol. HDL particles are able to remove cholesterol from within artery atheroma and transport it back to the liver for excretion or
re-utilization, which is the main reason why the cholesterol carried within HDL particles (HDL-C) is sometimes called "good cholesterol" (despite the fact that it is exactly the same as the cholesterol in LDL particles). Those with higher levels of HDL-C seem to have fewer problems with cardiovascular diseases, while those with low HDL-C cholesterol levels (less than 40 mg/dL or about 1 mmol/L) have increased rates for heart disease. (Ugbaja et al., 2015).

In this study, the 10% *Hura crepitans* seed oil proved to be quite effective in lowering the RBC cholesterol level and the increased triglycerides in the plasma and HDL fraction.

Phospholipids were increased in plasma, VLDL-LDL and HDL in all the group. These may be because, the diet generated a high level of circulating free fatty acids which favoured synthesis of triacylglycerols in the adipose tissue and major phospholipids in the blood probably by up-regulating the enzyme involved in the synthesis of these lipids.

Also, it is known that diets rich in unsaturated fatty acids, mainly PUFAs, increase LDL receptor activity (Shepherd et al., 1980) increasing the uptake of cholesterol into tissues, and decrease very low density lipoprotein (VLDL) and LDL production rates (Turner et al., 1981; Cortese et al., 1983) followed by diminished circulating cholesterol concentration. The oils do not contain cholesterol, so the increase observed in the groundnut oil groups may be due to activation of HMG-CoA reductase and the rate limiting enzyme in cholesterol synthesis (Sawada et al., 2005). The mechanism of the oil being able to do this is not yet understood, but it could be due to changes in the quantity of enzyme protein which is relatively slow compared to the rapid changes that occur from phosphorylation-dephosphorylation of the enzyme (Kennelly and Rodwell, 1985).

In figure 1, there was no significant different in all the groups except in 10 % HCSO group when comparing it with the control, this shows that there was a decrease in the activity of the HMG CoA reductase enzyme in the 10 % HCSO group.

In this study, it was discovered that the rats fed with *Hura crepitans* seed oil had a decreased cholesterol concentration compared to the groundnut oil group.

There was a decreased in the activity of the HMG CoA reductase enzyme in the *Hura crepitans* seed oil group compared to the groundnut oil group.

The result of this study implied that *Hura crepitans* seed oil was able to decrease the level of cholesterol and triacylglycerol in the RBC, kidney, liver and heart particularly at 10% composition. Therefore *Hura crepitans* seed oil is considerably hypolipidemic and edible especially at 10% composition.
