Abstract

We consider lepton mixing in an extension of the Standard Model with three right-handed neutrino singlets. We require that the three lepton numbers $L_e$, $L_\mu$, and $L_\tau$ be separately conserved in the Yukawa couplings, and we assume that they are softly broken only by the Majorana mass matrix $M_R$ of the neutrino singlets. In this framework, where lepton-number breaking occurs at a scale much higher than the electroweak scale, deviations from family-lepton-number conservation are calculable and finite, and lepton mixing stems exclusively from $M_R$. We then show that a discrete symmetry exists such that, in the lepton mixing matrix $U$, maximal atmospheric neutrino mixing together with $U_{e3} = 0$ can be obtained naturally. Alternatively, if one assumes that there are two different scales in $M_R$ and that the lepton number $\bar{L} = L_e - L_\mu - L_\tau$ is conserved in between them, then maximal solar neutrino mixing follows naturally. If both the discrete symmetry and intermediate $\bar{L}$ conservation are introduced, bimaximal mixing is achieved.

1 Introduction

At present the positive results of some experimental searches for neutrino oscillations provide the only glimpse of physics beyond the Standard Model (SM). In particular, the results of the atmospheric and solar neutrino experiments have a natural explanation in terms of neutrino oscillations and, therefore, in terms of non-zero light-neutrino masses $m_k$ ($k = 1, 2, 3$) and lepton mixing. Atmospheric neutrino results are well fitted by a mass-squared difference $\Delta m^2_{\text{atm}} = |m_3^2 - m_2^2| \approx 3 \times 10^{-3}$ eV$^2$ and a mixing angle $\psi \sim 45^\circ$. The situation for solar neutrinos is not that clear-cut: several viable explanations of the solar-neutrino deficit seem to exist (for recent analyses see \cite{3, 4, 5, 6}; for the latest experimental results of Super-Kamiokande see \cite{7}). The large-mixing-angle (LMA) MSW solution has $\Delta m^2_{\odot} = |m_2^2 - m_1^2| \approx 3 \times 10^{-5}$ eV$^2$ and a large mixing angle $\theta$; the small-mixing-angle (SMA) MSW solution features $\Delta m^2_{\odot} \approx 5 \times 10^{-6}$ eV$^2$ and $\tan^2 \theta \approx 6 \times 10^{-3}$; finally, the LOW solution has $\Delta m^2_{\odot} \approx 10^{-7}$ eV$^2$ and a large mixing angle, possibly reaching 45$^\circ$. (All these numbers have been taken from \cite{4}.)

The problem of neutrino masses and lepton mixing can be separated into two questions. The first one concerns mechanisms for achieving neutrino masses which are much smaller than the charged-lepton masses; the seesaw mechanism \cite{9} figures as a prominent solution to this problem and will be adopted in the present paper. The second question concerns the specific features of the lepton mixing matrix $U$; in particular, how can an atmospheric mixing angle close to 45$^\circ$, and a very small $U_{e3}$ \cite{10} (see also \cite{5, 6}), be explained. This second question has been viewed from many different angles (see for instance \cite{11}) and no preferred solutions have emerged yet. In particular, it has been observed \cite{12} that the lepton number $\bar{L} = L_e - L_\mu - L_\tau$, which must be broken at some stage \cite{13} to obtain $\Delta m^2_{\odot} \neq 0$, leads to maximal solar mixing—see also \cite{14} and the references therein. This is certainly an interesting observation, but it may be argued that explaining maximal atmospheric mixing should have a higher priority than explaining maximal solar mixing—since the latter is not yet firmly established by experiment. Now, it has proven difficult to obtain maximal atmospheric mixing in a natural fashion (i.e., protected by some symmetry), in particular because the charged-lepton mass matrix may be non-diagonal and blur the picture of mixing following from the neutrino mass matrix.

In the present paper we take up and expand the idea of using lepton numbers for enforcing desired features upon the mixing matrix $U$. We start from the lepton sector of the SM enlarged by three right-handed neutrino singlets with Majorana mass terms given by the mass matrix $M_R$. The scalar sector of our theory consists only of SU(2) doublets and we do not introduce other scalar multiplets like singlets or triplets. The main idea of our work is to impose separate conservation of the family lepton numbers $L_e$, $L_\mu$, and $L_\tau$ (for a recent review on the status of lepton numbers see \cite{15}) and to allow them to be broken only softly, a breaking which may occur exclusively in $M_R$. Thus, the family lepton numbers are broken by mass terms of dimension three at a scale much higher than the electroweak scale. Under these conditions, lepton-number-breaking processes have calculable and finite amplitudes. This framework has the advantage that lepton mixing originates solely in the neutrino Majorana mass matrix $M_R$; contributions to $U$ from the charged-lepton mass matrix are naturally forbidden at tree level by the assumed conservation of the family lepton numbers in all terms of dimension four in the
Lagrangian. In this framework, we then show that it is possible to impose a discrete symmetry which leads to maximal atmospheric mixing and to $U_{e3} = 0$ (i.e., decoupled solar and atmospheric neutrino oscillations \[16\]). Alternatively, it is possible to have two different mass scales $m_R \ll \bar{m}_R$ in $M_R$ such that for energies in between $m_R$ and $\bar{m}_R$ the lepton number $\bar{L}$ is conserved; we then arrive at a scenario with maximal solar mixing.\[1\] Both scenarios may be combined to yield bimaximal neutrino mixing \[17\].

In section 2 we discuss the SM with family lepton numbers broken exclusively by the Majorana mass terms of right-handed neutrino singlets. We show that flavour-changing neutral interactions are not enhanced in spite of the large right-handed mass scale. In section 3 we introduce a model which naturally yields maximal atmospheric mixing, whereas in section 4 we discuss intermediate $\bar{L}$ conservation and maximal solar mixing. Both features are combined in section 5. The conclusions of this paper are found in section 6.

2 The framework

The framework within which we develop our models consists of the lepton sector of the SM with three families together with three right-handed neutrino singlets $\nu_R$. We allow for an arbitrary number $n_H$ of Higgs doublets $\phi_j$ ($j = 1, \ldots, n_H$) and use the notation

$$\phi_j = \begin{pmatrix} \varphi_j^+ \\ \varphi_j^0 \end{pmatrix}$$

and

$$\langle 0 | \varphi_j^0 | 0 \rangle = \frac{v_j}{\sqrt{2}}.$$  \hspace{1cm} (1)

We first compile various well-known formulae to fix the notation. The right-handed neutrino singlets have a Majorana mass term

$$\mathcal{L}_M = \frac{1}{2} v_R^T C^{-1} M_R^* \nu_R^T - \frac{1}{2} \bar{v}_R M_R C \bar{v}_R^T,$$  \hspace{1cm} (2)

where $M_R$ is symmetric. We define the left-handed neutrino singlets $\nu'_L \equiv C \bar{v}_R^T$, then

$$\mathcal{L}_M = \frac{1}{2} \nu'_L^T C^{-1} M_R \nu'_L - \frac{1}{2} \bar{v}_L M_R^* \bar{v}_L^T.$$  \hspace{1cm} (3)

The Yukawa Lagrangian of the leptons is given by

$$\mathcal{L}_Y = - \sum_{j=1}^{n_H} \left[ \ell_R \left( \varphi_j^-, \varphi_j^{0*} \right) \Gamma_j + \bar{\nu}_R \left( \varphi_j^0, -\varphi_j^+ \right) \Delta_j \right] \begin{pmatrix} \nu_L \\ \ell_L \end{pmatrix} + \text{h.c.}$$  \hspace{1cm} (4)

Defining the charged-lepton mass matrix $M_\ell$ and the Dirac neutrino mass matrix $M_D$ as

$$M_\ell = \frac{1}{\sqrt{2}} \sum_j v_j \Gamma_j \quad \text{and} \quad M_D = \frac{1}{\sqrt{2}} \sum_j v_j \Delta_j,$$  \hspace{1cm} (5)

respectively, we have from $\mathcal{L}_Y$ the following mass terms for the charged leptons and for the neutrinos:

$$\mathcal{L}_{Y_{\text{mass}}} = -\ell_R M_\ell \ell_L + \frac{1}{2} \nu'_L^T C^{-1} M_D \nu'_L + \frac{1}{2} \nu_L^T C^{-1} M_D^T \nu'_L + \text{h.c.}$$  \hspace{1cm} (6)

\[1\] An earlier variant of this idea, with two right-handed neutrino singlets only, was proposed in \[14\].
The Dirac and Majorana mass terms for the neutrinos may be written together as
\[ \frac{1}{2} \left( \nu_L^T, \nu_L^T \right) C^{-1} M_{D+M} \left( \nu_L \right) + \text{h.c.} \text{ with } M_{D+M} = \begin{pmatrix} 0 & M_D^T \\ M_D & M_R \end{pmatrix}. \] (7)

We assume that there are (at least) two mass scales in the theory: the electroweak scale, i.e., the one of the vacuum expectation values \( v_j \), and the scale of the Majorana mass terms, i.e., the one of the eigenvalues of \( \sqrt{M_R^* M_R} \). The latter scale is assumed to be much higher than the electroweak scale. Then, the neutrino fields participating in the weak interaction, \( \nu_L \), have effective Majorana mass terms given by
\[ \mathcal{L}_m = \frac{1}{2} \nu_L^T C^{-1} \mathcal{M}_\nu \nu_L + \text{h.c.}, \] (8)

with the (approximate) \( 3 \times 3 \) seesaw mass matrix \( \mathcal{M}_\nu = -M_D^T M_R^{-1} M_D \). (9)

The \( 6 \times 6 \) Majorana mass matrix of eq. (7) is diagonalized by the unitary matrix \( U \) such that
\[ U^T M_{D+M} U = \hat{m} = \text{diag} \left( m_1, \ldots, m_6 \right), \] (10)

where \( m_{1,2,3} \) are seesaw-suppressed whereas \( m_{4,5,6} \) are very large. It is useful to decompose \( U \) into two \( 3 \times 6 \) matrices \( U_L \) and \( U_R \) in the following way:
\[ U = \begin{pmatrix} U_L \\ U_R^* \end{pmatrix} \approx \begin{pmatrix} 1 & M_D^T M_R^{-1} \\ -M_R^{-1} M_D & 1 \end{pmatrix} \begin{pmatrix} V & 0 \\ 0 & W^* \end{pmatrix}, \] (11)

where, in the second part of the equation, \( U \) has been given to leading order in the inverse of the high scale \( \text{[13]} \). At that order, the \( 3 \times 3 \) unitary matrices \( V \) and \( W \) are defined by
\[ V^T \mathcal{M}_\nu V = \text{diag} \left( m_1, m_2, m_3 \right) \quad \text{and} \quad W^T M_R W^* = \text{diag} \left( m_4, m_5, m_6 \right). \] (12)

The foundation of our models lies in the assumption of the conservation of all three lepton numbers \( L_\alpha (\alpha = e, \mu, \tau) \) in the Yukawa couplings and, in general, in all terms of the Lagrangian with dimension four. This means that the three right-handed charged leptons \( \ell_R \) may from the start receive generation labels—we call them \( e_R, \mu_R, \) and \( \tau_R \). Similarly, each of the three right-handed neutrinos \( \nu_R \) carries one unit of the corresponding lepton number \( L_\alpha \), and is accordingly named \( \nu_{e_R}, \nu_{\mu_R}, \) or \( \nu_{\tau_R} \). Finally, the three left-handed lepton doublets \( (\nu_L, \ell_L)^T \) will be called \( D_e, D_\mu, \) and \( D_\tau \). The Yukawa coupling matrices \( \Gamma_j \) and \( \Delta_j \), and the mass matrices \( M_i \) and \( M_D \), are all simultaneously diagonal. The generation lepton numbers \( L_\alpha \) are broken explicitly but softly only by the dimension-three mass terms in \( \mathcal{L}_M \) of eq. \( \text{[2]} \).

As \( M_i \) is diagonal, and since in our model there are three charged leptons together with six neutrinos, the \( 3 \times 6 \) matrix \( U_L \) in eq. \( \text{[11]} \) is the lepton mixing matrix. The part

\[ \text{[9]}
\]
of the mixing matrix relevant for the light neutrinos is approximately unitary and is given by $V$; up to a phase convention, this matrix is usually called the neutrino mixing matrix $U$, i.e.,

$$V = e^{i\alpha} U e^{i\beta},$$

(13)

where the diagonal phase matrix $e^{i\alpha}$ has no physical meaning (it may be absorbed in the phases of the charged-lepton fields) while the diagonal phase matrix $e^{i\beta}$ contains phases which appear only in the lepton-number-violating processes typical of the Majorana character of the neutrinos.

We claim that in this framework, in any process, the deviation from family-lepton-number conservation proceeds in a finite and calculable way, controlled by the elements of $M_R$. In particular, radiative corrections introduce flavour-changing interactions of the neutral scalars due to $L M_L$. At one-loop level, the logarithmic term induced by charged-Higgs exchange, which contains the leading term, is given by

$$\Delta \Gamma_{j,FC} = -\frac{1}{16\sqrt{2} \pi^2} \sum_{i=1}^{n_H} \Gamma_i \Delta_i^\dagger U_R \ln \left( \frac{\hat{m}_i^2}{m^2} \right) U_R^\dagger \Delta_i,$$

(14)

where $U_R$ is the $3 \times 6$ matrix introduced in eq. (11). The mass $m$ is arbitrary, since only the off-diagonal terms of eq. (14), which are finite and $m$-independent, have physical significance. If we choose $m$ to be the right-handed-neutrinos mass scale, we see that the large logarithms $\ln \left( \frac{m_{1,2,3}^2}{m^2} \right)$ are suppressed by small mixing angles in $U_R$. The flavour-changing neutral interactions are weak because they are cubic in the Yukawa coupling constants. This guarantees that our theory is viable. For instance, there is a stringent bound of order $10^{-12}$ on the branching ratio of $\mu^+ \rightarrow e^- e^+ e^-$ [21]. With the result of eq. (14) we can estimate that branching ratio to be of order $\frac{Y^8}{(16\pi^2 G_F m_H^2)^2}$, where $Y$ is a typical Yukawa coupling and $m_H$ is a typical neutral-scalar mass. Taking $m_H \sim 100$ GeV and $Y \sim 10^{-3} - 10^{-2}$ ($Y$ should be of order of a charged-lepton mass divided by the Fermi scale), we obtain a branching ratio of $10^{-18}$ or smaller, quite safe when compared to the experimental bound.

Charged-scalar exchange also induces the radiative decay $\mu^+ \rightarrow e^- \gamma$, which has an experimental upper bound on its branching ratio of order $10^{-11}$ [21]. As before, the transition amplitude for this decay has both light and heavy neutrinos in the loop. There is also a chirality flip and, therefore, a mass insertion. The calculation of $\mu^+ \rightarrow e^- \gamma$ in the present theory is not similar to the one in the context of the Zee model [22], but rather to the ones in the context of supersymmetric models—see for instance [23]. The branching ratio of $\mu^+ \rightarrow e^- \gamma$ is suppressed in our model not only by the fine-structure constant $\alpha$ and a product of four Yukawa couplings, but also due to a GIM mechanism [24]. A crude estimate of an upper bound on this branching ratio is given by $\alpha Y^4 / (\pi G_F m_H^2)$, where $m_R$ denotes the scale of the Majorana mass terms of the right-handed neutrinos. This one-loop estimate is far below the present experimental bound. A detailed account of this decay and of other flavour-changing decays in the context of our framework will be presented in a forthcoming paper [20].

3This term originates in the vertex correction with the charged scalars in the loop. The flavour-changing interactions will be studied in detail in a forthcoming paper [20].
3 Maximal atmospheric mixing

Within the theory described in the previous section it is possible to implement maximal atmospheric mixing naturally. A key to this possibility is the conservation of the lepton numbers $L_e, L_\mu, L_\tau$ in the Yukawa interactions, making the charged-lepton mass matrix diagonal; we have to worry only about the form of $M_R$ and $M_D$. We consider $n_H = 3$ and introduce two $Z_2$ symmetries:

\[ Z_2^{(1)}: \quad \nu_{\mu R} \leftrightarrow \nu_{\tau R}, \quad D_\mu \leftrightarrow D_\tau, \quad \mu_R \leftrightarrow \tau_R, \quad \phi_3 \rightarrow -\phi_3; \quad (15) \]
\[ Z_2^{(2)}: \quad \mu_R \rightarrow -\mu_R, \quad \tau_R \rightarrow -\tau_R, \quad \phi_2 \rightarrow -\phi_2, \quad \phi_3 \rightarrow -\phi_3. \quad (16) \]

Fields not appearing in these equations transform trivially. Let us motivate these choices. Because of $Z_2^{(1)}$ we have

\[ (M_R)_{e\mu} = (M_R)_{e\tau} \quad \text{and} \quad (M_R)_{\mu\mu} = (M_R)_{\tau\tau}. \quad (17) \]

As $\phi_2$ and $\phi_3$ change sign under $Z_2^{(2)}$, only $\phi_1$ has Yukawa couplings to the neutrinos:

\[ \mathcal{L}_Y(\nu_R) = -\sqrt{2} \left( \frac{\varphi_1^0}{v_1}, -\varphi_1^{+} \right) [a\bar{\nu}_{eR}D_e + b(\bar{\nu}_{\mu R}D_\mu + \bar{\nu}_{\tau R}D_\tau)] + \text{h.c.}, \quad (18) \]

cf. eq. (4). Thus,

\[ M_D = \text{diag}(a, b, b) \quad (19) \]

has identical $\mu$ and $\tau$ entries, once again because of $Z_2^{(1)}$. As a consequence, the light-neutrino Majorana mass matrix has the same structure as $M_R$:

\[ M_\nu = \begin{pmatrix} x & y & y \\ y & z & w \\ y & w & z \end{pmatrix}. \quad (20) \]

Maximal atmospheric neutrino mixing and $U_{e3} = 0$ immediately follow from this structure of $M_\nu$\(^4\). Using an adequate phase convention, cf. eq. (13), to transit from the unitary matrix $V$ which diagonalizes $M_\nu$ to the neutrino mixing matrix $U$, we obtain

\[ U = \begin{pmatrix} \cos \theta & \sin \theta & 0 \\ \sin \theta/\sqrt{2} & -\cos \theta/\sqrt{2} & -1/\sqrt{2} \\ \sin \theta/\sqrt{2} & -\cos \theta/\sqrt{2} & 1/\sqrt{2} \end{pmatrix}. \quad (21) \]

Indeed, as the charged-lepton mass matrix is diagonal within our general framework, the matrix $U$ is already the neutrino mixing matrix. The third column of $U$ in eq. (21) is an eigenvector of the mass matrix $M_\nu$ of eq. (20). The form of the other two columns of $U$ follows from the form of the third column. At tree level the atmospheric mixing angle is

\[^4\text{This structure of } M_\nu \text{ in the basis where the charged-lepton mass matrix is diagonal has been suggested by several authors, e.g. } [25, 26, 27]. \text{ We stress that in our case this structure results from a symmetry, i.e., we have a model and not just a texture for } M_\nu.\]
exactly 45°, whereas the solar mixing angle \(\theta\) is free. Without loss of generality we may assume \(m_1 < m_2\) and \(0° < \theta < 90°\).

Up to now a single Higgs doublet \(\phi_1\) was needed. Coming to the charged-lepton masses, we obviously have to break \(Z_2^{(1)}\) in order to avoid \(m_\mu = m_\tau\). This is achieved by introducing two more doublets \(\phi_2\) and \(\phi_3\), one of them being even and the other one being odd under \(Z_2^{(1)}\). These doublets must not couple to \(\nu_R\) because we want to avoid destruction of the form of \(M_D\) in eq. (19); this is the rationale for introducing the symmetry \(Z_2^{(2)}\). We obtain the following Yukawa couplings to the charged leptons:

\[
L_Y(\ell_R) = -\sqrt{2} m_e \left( \phi_1^\dagger, \phi_1^{0*} \right) \bar{\ell}_R D_e \\
-\sqrt{2} d \left( \phi_2^-, \phi_2^{0*} \right) (\mu_R D_\mu + \bar{\tau}_R D_\tau) \\
-\sqrt{2} d' \left( \phi_3^-, \phi_3^{0*} \right) (\mu_R D_\mu - \bar{\tau}_R D_\tau) + \text{h.c.},
\]

yielding

\[
m_\mu = |d v_2^* + d' v_3^*|, \quad (23)
m_\tau = |d v_2^* - d' v_3^*|. \quad (24)
\]

This allows for \(m_\mu \neq m_\tau\), with some finetuning in order to obtain \(m_\tau \gg m_\mu\). Such a finetuning is, anyway, needed even within the SM.

We need to check that the Higgs potential is such that it does not possess any \(U(1)\) symmetries apart from the weak hypercharge \(U(1)_Y\). In particular, we easily see that all terms of the form \((\phi_i^\dagger \phi_j)^2\) are allowed by both \(Z_2^{(1)}\) and \(Z_2^{(2)}\); therefore, there are no unwanted Goldstone bosons and all the physical-scalar masses can be made sufficiently heavy, of the order of the weak scale. Notice that both \(Z_2^{(1)}\) and \(Z_2^{(2)}\) are broken spontaneously, but at tree level this breaking is not felt in the neutrino sector.

In our model the seesaw mechanism is operative. If we assume \(a\) and \(b\) to be of order \(m_\nu^D \sim 0.1–1\) GeV (where \(m_\nu^D\) is a typical charged-lepton mass), and if \(m_R^2\) is the order of magnitude of the eigenvalues of \(M_R M_R^\dagger\), then we obtain the order-of-magnitude estimate

\[
\sqrt{\Delta m^2_{\text{atm}}} \sim (m_\nu^D)^2/m_R, \quad \text{which gives } m_R \sim 10^8–10^{10} \text{ GeV}.
\]

Let us deal a bit longer with \(\mathcal{M}_\nu\) of eq. (20). The neutrino masses are given by

\[
m_3 = |z - w| \quad (25)
\]

and

\[
m_{1,2}^2 = \frac{1}{2} \left[ |x|^2 + 4|y|^2 + |z + w|^2 \mp \sqrt{(|x|^2 + 4|y|^2 + |z + w|^2)^2 - 4|x(z + w) - 2y|^2} \right]. \quad (26)
\]

The solar mixing angle is expressed as

\[
tan 2\theta = 2\sqrt{2} \frac{|x^* y + y^*(z + w)|}{|z + w|^2 - |x|^2}. \quad (27)
\]

Notice in particular that the only physical phase in \(\mathcal{M}_\nu\) is

\[
\beta = \arg x + \arg(z + w) - 2 \arg y. \quad (28)
\]
Indeed, we have

\[
\tan 2\theta = 2\sqrt{2} |y| \frac{|e^{i\beta} |z + w| + |x| |}{|z + w|^2 - |x|^2} \tag{29}
\]

and

\[
\Delta m^2_\odot = \sqrt{\left( |z + w|^2 - |x|^2 \right)^2 + 8 |y|^2 |e^{i\beta} |z + w| + |x|^2} . \tag{30}
\]

Combining these two equations leads to \[26\]

\[
\Delta m^2_\odot \cos 2\theta = |z + w|^2 - |x|^2 , \tag{31}
\]

where we have taken into account that, by definition, \( \theta \) lies in the first quadrant. This model does not allow to relate \( \Delta m^2_\odot \) with \( \Delta m^2_{\text{atm}} \), since \( m_3 \) is independent from \( m_{1,2} \).

Given any values of \( \Delta m^2_\odot \), \( \Delta m^2_{\text{atm}} \), and \( \theta \), they can be reproduced within the present model. First we use eq. \[31\] to express \( |z + w| \), plug this expression into eq. \( \underline{27} \) and arrive at

\[
\sin 2\theta = 2\sqrt{2} \frac{|x| |y|}{\Delta m^2_\odot} \left( 1 + e^{i\beta} \sqrt{1 + \Delta m^2_\odot \cos 2\theta/|x|^2} \right) . \tag{32}
\]

Obviously, by choosing \( |x| \) and \( |y| \) we can achieve any desired value of \( \theta \), and by choosing \( |z - w| = m_3 \) we reproduce the experimental value of the atmospheric mass-squared difference.

Let us now address the question of whether one can still fit any values of \( \Delta m^2_\odot \), \( \Delta m^2_{\text{atm}} \), and \( \theta \), when \( |x|, |y|, |z + w|, \) and \( |z - w| \) are all assumed to be of order \( \sqrt{\Delta m^2_{\text{atm}}} \). A glance at eq. \( \underline{32} \) shows that this is impossible for \( |1 + e^{i\beta}| \gg \Delta m^2_\odot / \Delta m^2_{\text{atm}} \). However, if we assume for simplicity that \( e^{i\beta} = -1 \), then we have

\[
\tan 2\theta \approx \sqrt{2} \frac{|y|}{|x|} \tag{33}
\]

and, in general, we have a large solar neutrino mixing. Naturally, with our order-of-magnitude assumption on the absolute values, finetuning is required to make the solar mass-squared difference small. This finetuning is expressed, e.g., by eq. \( \underline{31} \) \[20\].

At this stage it is appropriate to ask whether there is any reason for having \( e^{i\beta} = -1 \). Since we need a real phase factor, we explore the effect of \( CP \) invariance:

\[
CP : \quad D_\alpha \to \gamma^0 C \tilde{D}_\alpha^T , \quad \ell_R \to \gamma^0 C \ell_R^T , \quad \nu_R \to \gamma^0 C \nu_R^T , \quad \phi_j \to \phi_j^* . \tag{34}
\]

This \( CP \) symmetry leads to real Yukawa-coupling matrices \( \Gamma_j \) and \( \Delta_j \), while \( M_R \) is imaginary. With eq. \( \underline{3} \) and the definition of \( \beta \) it is easy to check that\[5\]

\[
e^{i\beta} = \text{sign} \left\{ (M_R)_{ee} \left[ (M_R)_{\mu\mu} + (M_R)_{\mu\tau} \right] / (M_R)_{e\mu}^2 \right\} = -\text{sign} \left\{ (M_R)_{ee} \left[ (M_R)_{\mu\mu} + (M_R)_{\mu\tau} \right] \right\} . \tag{35}
\]

It is thus natural to have \( \beta = \pi \) if we invoke \( CP \) invariance. In this case, with all the matrix elements of \( M_\nu \) of order \( \sqrt{\Delta m^2_{\text{atm}}} \), the only remaining finetuning which is required is to make \( |z + w| - |x| \) sufficiently small, see eq. \( \underline{30} \).

\[5\]Note that we have the requirement \( (M_R)_{\mu\mu}^2 \neq (M_R)_{\mu\tau}^2 \). Indeed, for \( (M_R)_{\mu\mu} = (M_R)_{\mu\tau} \) the matrix \( M_R \) is singular, while for \( (M_R)_{\mu\mu} = - (M_R)_{\mu\tau} \) we have \( x = 0 \) and the phase \( \beta \) is not defined.
4 Maximal solar mixing

In this section we dispense with the \( Z_2^{(1)} \) and \( Z_2^{(2)} \) symmetries of the previous section. Our present aim is to show that, if one assumes the three individual lepton numbers \( L_e, L_\mu, \) and \( L_\tau \) to be broken down at some high scale \( \bar{m}_R \) to their linear combination \( \bar{L} = L_e - L_\mu - L_\tau, \) and one further assumes that \( \bar{L} \) only gets broken at a much lower scale \( m_R \) \([4]\), then approximate maximal solar neutrino mixing follows. The crucial point is that the assumption of \( \bar{L} \) conservation in between the two high scales \( \bar{m}_R \) and \( m_R \) is natural in the technical sense, since \( \bar{L} \) is a symmetry, and therefore maximal solar mixing is a natural option in the context of our framework.

Let us define the small dimensionless parameter \( \epsilon = m_R/\bar{m}_R \ll 1. \) The mass matrix \( M_R \) then has the form

\[
M_R = \begin{pmatrix}
  u & p/\epsilon & q/\epsilon \\
p/\epsilon & r & t \\
q/\epsilon & t & s
\end{pmatrix},
\]

where \( u, p, q, r, s, \) and \( t \) are assumed to be all of order of magnitude \( m_R. \) Indeed, intermediate \( \bar{L} \) conservation implies that the \((e, \mu)\) and \((e, \tau)\) entries of \( M_R \) are the only ones to be of order \( \bar{m}_R. \) Taking into account that \( M_D = \text{diag}(a, b, c) \) is diagonal, we find that the seesaw neutrino mass matrix of eq. \([5]\) is

\[
M_\nu = \frac{1}{p^2 s + q^2 r - 2 p q t + \epsilon^2 u (t^2 - r s)} \begin{pmatrix}
e^2 a^2 (r s - t^2) & e a b (q t - p s) & e a c (p t - q r) \\
e a b (q t - p s) & b^2 (\epsilon^2 u s - q^2) & b c (p q - \epsilon^2 u t) \\
e a c (p t - q r) & b c (p q - \epsilon^2 u t) & c^2 (\epsilon^2 u r - p^2)\end{pmatrix}.
\]

Notice that only the \((\mu, \mu), (\tau, \tau), \) and \((\mu, \tau) = (\tau, \mu)\) matrix elements of \( M_\nu \) are not \( \epsilon \)-suppressed; still,

\[
(M_\nu)_{\mu \mu} (M_\nu)_{\tau \tau} - (M_\nu)_{\mu \tau} (M_\nu)_{\tau \mu} = \frac{-\epsilon^2 b^2 c^2 u}{p^2 s + q^2 r - 2 p q t + \epsilon^2 u (t^2 - r s)}
\]

is suppressed by two powers of \( \epsilon, \) and this fact is crucial in the following.

We shall perform an expansion in the small parameter \( \epsilon \) and compute the subleading order in \( \epsilon \) of the relevant quantities. This is consistent with our use of the seesaw formula of eq. \([4]\); indeed, if one wanted to compute sub-subleading orders in the \( \epsilon \) expansion one would first need a better version of the seesaw expansion of \( M_\nu \) \([23]\).

For the sake of simplicity we shall assume the matrix \( M_\nu \) of eq. \([37]\) to be real.\(^6\) This allows us to diagonalize it by simply looking for its eigenvalues and eigenvectors. Thus,

\[
U^T M_\nu U = \text{diag} (\eta_1 m_1, \eta_2 m_2, \eta_3 m_3),
\]

where the \( \eta_k \) may be either +1 or −1, and \( U \) is the neutrino mixing matrix as usual. If \( M_\nu \) was not real one would first have to diagonalize \( M_\nu M_\nu^*, \) and that would of course be quite more tedious. One of the eigenvalues (say, \( \lambda_0 \)) of \( M_\nu \) is of order \((m_D^0)^2/m_R, \) and

\(^6\)By imposing the \( C P \) symmetry of eq. \([34]\), and with the help of a phase transformation, the imaginary matrix \( M_R \) can be made real while keeping \( M_D \) real. Then \( M_\nu \) will be real too.
the other two (we call them $\lambda_{\pm}$) are smaller, of order $(m_{\nu}^D)^2/\bar{m}_R$, because of eq. (38). The eigenvalues $\lambda_{\pm}$ fulfill $|\lambda_+| = |\lambda_-|$ to leading order in $\epsilon$, which means that $\Delta m^2_\odot$ vanishes to that order. Explicitly, to subleading order in $\epsilon$

$$\lambda_0 = \frac{-F^2}{p^2 s + q^2 r - 2pqt},$$

$$\lambda_{\pm} = \pm \frac{abc}{F} + \frac{\epsilon^2 (a^2 b^4 q^2 s + a^2 c^4 p^2 r + 2a^2 b^2 c^2 pqt + b^2 c^2 F^2 u)}{2F^4},$$

where

$$F \equiv \sqrt{b^2 q^2 + c^2 p^2}. \quad (42)$$

It follows that

$$\frac{\Delta m^2_\odot}{\Delta m^2_{\text{atm}}} \simeq \left| \frac{\lambda_+^2 - \lambda_-^2}{\lambda_0^2} \right|$$

$$\simeq \left| \frac{2\epsilon^3 abc (p^2 s + q^2 r - 2pqt)^2 (a^2 b^4 q^2 s + a^2 c^4 p^2 r + 2a^2 b^2 c^2 pqt + b^2 c^2 F^2 u)}{F^9} \right|$$

is of order $\epsilon^3$. Maximal solar neutrino mixing is allowed at 90% CL in the LOW solution with $\Delta m^2_\odot \sim 10^{-7} \text{ eV}^2$, giving the estimate $\epsilon^3 \sim 10^{-4}$. In this case $\epsilon$ is small enough for a sensible expansion. Approximate maximal mixing is also possible in the LMA MSW solution, but then only at 99% CL \[4\]; in that case $\epsilon^3 \sim 10^{-2}$ is rather large and the two scales $m_R$ and $\bar{m}_R$ are not so clearly separated.

To subleading order in $\epsilon$, the normalized eigenvector corresponding to the eigenvalue $\lambda_0$ is

$$\begin{pmatrix}
\frac{1}{\sqrt{2}} [1 \pm \epsilon (\frac{abcqt}{2F^3} + \frac{ac^3 p^2 r}{4bF^3} + \frac{ab^3 q^2 s}{4cF^3} - \frac{bcu}{4aF})] \\
-bq/F \sin \psi/\sqrt{2} \\
cp/F \cos \psi/\sqrt{2}
\end{pmatrix},$$

and the ones corresponding to the eigenvalues $\lambda_{\pm}$ are

$$\begin{pmatrix}
\frac{1}{\sqrt{2}} [1 \pm \epsilon (\frac{abcqt}{2F^3} + \frac{ac^3 p^2 r}{4bF^3} + \frac{ab^3 q^2 s}{4cF^3} - \frac{bcu}{4aF})] \\
\frac{cp}{\sqrt{2}F} [1 \pm O(\epsilon)] \\
\frac{bq}{\sqrt{2}F} [1 \pm O(\epsilon)]
\end{pmatrix},$$

respectively. It follows that, to leading order, the mixing matrix $U$ is

$$U = \begin{pmatrix}
1/\sqrt{2} & 1/\sqrt{2} & 0 \\
\sin \psi/\sqrt{2} & -\sin \psi/\sqrt{2} & -\cos \psi \\
\cos \psi/\sqrt{2} & -\cos \psi/\sqrt{2} & \sin \psi
\end{pmatrix}, \quad \text{with} \quad \sin \psi \equiv cp/F, \cos \psi \equiv bq/F. \quad (46)$$
Thus, $U_{e3} = 0$ and maximal solar mixing hold at leading order. At subleading order

$$U_{e3} = \epsilon \frac{a [(b^2 q^2 - c^2 p^2) t + pq (c^2 r - b^2 s)]}{F^3},$$  

$$\sin^2 2\theta = 1 - \epsilon^2 \left( \frac{abcpt}{F^3} + \frac{ac^3 p^2 r}{2bF^3} + \frac{ab^3 q^2 s}{2cF^3} - \frac{bcu}{2aF} \right)^2.$$  

It is worth emphasizing that $\Delta m^2_{\odot} / \Delta m^2_{\text{atm}}$ is of order $\epsilon^3$ while $1 - \sin^2 2\theta$ is proportional to $\epsilon^2$ only. This means that, for solutions of the solar neutrino problem with a higher value of $\Delta m^2_{\odot} / \Delta m^2_{\text{atm}}$, such as the LMA MSW solution, we may allow $\sin^2 2\theta$ to be further away from unity. This gives us extra room in the fitting of the experimental data within the context of our model.

We also remark that some models based on $\bar{L}$ symmetry [14] predict a massless neutrino ($m_3 = 0$) which has zero component along the $\nu_e$ direction ($U_{e3} = 0$). The present model, on the contrary, allows for $U_{e3}$ to differ from 0 substantially (as it is only of order $\epsilon$) and, moreover, it predicts $m_3$ to be much larger than $m_1$ and $m_2$, instead of $m_3 = 0$. Note that our model displays $m_2 - m_1 \ll (m_1 + m_2)/2$, contrary to the orthodox hierarchical pattern of masses, where $m_1 \ll m_2$.

## 5 Bimaximal mixing

We may combine the assumptions of sections 3 and 4 to obtain a scheme with natural bimaximal mixing. In that scheme $M_D = \text{diag} (a, b, b)$ as in eq. (19) and

$$M_R = \begin{pmatrix} u & p/\epsilon & p/\epsilon \\ p/\epsilon & r & t \\ p/\epsilon & t & r \end{pmatrix},$$

with $\epsilon$ much smaller than 1, in analogy to eq. (36). Then, assuming once again $M_D$ and $M_R$ to be real for the sake of simplification (see footnote 6), we obtain

$$\lambda_0 = \frac{b^2}{t-r},$$

$$\lambda_{\pm} = \pm \frac{\epsilon ab}{\sqrt{2}p} + \frac{\epsilon^2 [a^2 (r + t) + b^2 u]}{4p^2},$$

and

$$\sin^2 2\theta = 1 - \frac{\epsilon^2}{8p^2} \left[ \frac{a}{b} (r + t) - \frac{b}{a} u \right]^2.$$  

Maximal atmospheric neutrino mixing and $U_{e3} = 0$ are exact results in this case.
Indeed, the full $6 \times 6$ neutrino mass matrix

$$
\mathcal{M}_{D+M} = \begin{pmatrix}
0 & 0 & 0 & a & 0 & 0 \\
0 & 0 & 0 & 0 & b & 0 \\
0 & 0 & 0 & 0 & 0 & b \\
a & 0 & 0 & u & p/\epsilon & p/\epsilon \\
0 & b & 0 & p/\epsilon & r & t \\
0 & 0 & b & p/\epsilon & t & r
\end{pmatrix}
$$

(53)

has an eigenvalue

$$(t - r) \left( \sqrt{1 + \sigma^2} - 1 \right) / 2 \simeq \frac{b^2}{t - r},$$

(54)

where

$$\sigma \equiv \frac{2b}{r - t}. $$

(55)

The above eigenvalue is seesaw-suppressed and its absolute value corresponds to $m_3$. To the exact eigenvalue (54) corresponds the exact eigenvector of $\mathcal{M}_{D+M}$

$$
\frac{1}{2 (1 + \sigma^2)^{1/4}} \begin{pmatrix}
0 \\
\sigma/\eta \\
-\sigma/\eta \\
0 \\
-\eta \\
\eta
\end{pmatrix}, \quad \text{with } \eta \equiv \sqrt{1 + \sigma^2} - 1 \simeq \frac{\sigma}{\sqrt{2}}.
$$

(56)

Note that both the eigenvalue and the eigenvector depend only on $b$ and on $r - t$; in particular, they depend neither on $a$ nor on $p$.

6 Conclusions

In this paper we have considered the extension of the SM with three right-handed neutrino singlets with large Majorana mass terms responsible for the seesaw mechanism. Upon this standard scenario we have imposed the separate conservation of the family lepton numbers $L_e, L_\mu$, and $L_\tau$ in the Yukawa couplings, such that these lepton numbers are softly broken solely by the Majorana mass terms. In this way, at tree level the charged-lepton mass matrix is automatically diagonal and lepton mixing originates exclusively in the Majorana mass matrix $M_R$.

This makes it relatively easy to impose a discrete symmetry which enforces $U_{e3} = 0$ and maximal atmospheric neutrino mixing; for this we need three Higgs doublets. An alternative model, with maximal solar mixing, is obtained when there are two different scales in $M_R$ such that, at the higher scale, the individual lepton numbers $L_e, L_\mu,$ and $L_\tau$ are broken down to $\bar{L} = L_e - L_\mu - L_\tau$; whereas at the lower scale $\bar{L}$ is also softly broken. In this case one Higgs doublet suffices. The two models can easily be combined if one wants to obtain bimaximal mixing.
In the model with maximal atmospheric mixing the ratio $\Delta m^2_\odot / \Delta m^2_{\text{atm}}$ has to be fitted by means of a finetuning. In the model with maximal solar mixing there is a relationship between the deviation of $\theta$ from $45^\circ$ and the ratio of the mass-squared differences, namely $1 - \sin^2 2\theta \sim \epsilon^2$ and $\Delta m^2_\odot / \Delta m^2_{\text{atm}} \sim \epsilon^3$, where $\epsilon$ is the ratio of the two scales in $M_R$.

The mechanisms for maximal neutrino mixing discussed in this paper are extremely simple and require only a minimal extension of the SM with right-handed singlets $\nu_R$. Apart from the possibility of obtaining maximal neutrino mixing in a natural way, the violation of $L_e$, $L_\mu$, and $L_\tau$ exclusively by the large Majorana masses of the $\nu_R$ constitutes in itself an interesting scenario, where deviations from the conservation of the family lepton numbers are calculable, finite, and controlled by $M_R$ only.
