Abstract We find an analytical condition characterising when the probability that a Lévy Process leaves a symmetric interval upwards goes to one as the size of the interval is shrunk to zero. We show that this is also equivalent to the probability that the process is positive at time $t$ going to one as $t$ goes to zero and prove some related sequential results. For each $\alpha > 0$ we find an analytical condition equivalent to $X_{T_r} r^{-1/\alpha} \overset{p}{\to} \infty$ and $X_{t} t^{-1/\alpha} \overset{p}{\to} \infty$ as $r, t \to 0$ where $X$ is a Lévy Process and $T_r$ the time it first leaves an interval of radius $r$.

Mathematics Subject Classification (2000)  60G51 · 60G17

1 Introduction

Let $X$ be a Lévy Process (LP); that is an $\mathbb{R}$-valued stochastic process with stationary, independent increments whose paths are taken to be almost surely right-continuous. (We assume some familiarity with LPs and for an account refer to Bertoin [2]). It can be shown that there is a one-to-one correspondence between LPs and infinitely divisible distributions. We have

$$E(e^{i\lambda X_t}) = e^{-t\psi(\lambda)}$$

P. Andrew (✉)

e-mail: p.andrew@blackburnmail.com
where we will write $\psi$ (the Lévy exponent) as follows:

$$
\psi(\lambda) = \frac{1}{2} \sigma^2 \lambda^2 - i \varphi \lambda + \int_{-\infty}^{\infty} \left(1 - e^{i\lambda x} + i \lambda x 1_{\{|x| \leq 1\}}\right) \Pi(dx);
$$

where $\sigma, \varphi \in \mathbb{R}$ and $\Pi$ (the jump measure) satisfies $\int_{-\infty}^{\infty} 1 \wedge |x|^2 \Pi(dx) < \infty$.

In this paper we are interested in results relating to the small-time behaviour of Lévy Processes, particularly in regard to positivity in probability and exit from small intervals. We give analytical conditions equivalent to $\mathbb{P}(X_{Tr} > 0) \to 1$, $\mathbb{P}(X_t > 0) \to 1$, $X_{Tr} T_r^{-1/\alpha} \overset{p}{\to} \infty$ and $X_t t^{-1/\alpha} \overset{p}{\to} \infty$ respectively. Many of these form analogues to large-time results for Random Walks (RWs). We discuss when these conditions are satisfied and investigate some related conditions in their sequential forms.

Note that since a non-zero Brownian component would dominate at small times we exclude this case. (i.e. We will henceforth assume that $\sigma = 0$.) Indeed, if we let $B_t$ be a standard Brownian Motion and $X_t$ a Lévy Process with zero Brownian component then it is a consequence of the results in Pruitt [13] (see Theorem 6 below or [6]) that

$$
\frac{B_t}{X_t} \overset{p}{\to} \infty \quad \text{as} \quad t \to 0,
$$

and thus if $X$ had a non-zero Brownian component then we would have $\lim_{t \downarrow 0} \mathbb{P}(X_t > 0) = \lim_{t \downarrow 0} \mathbb{P}(B_t > 0) = 1/2$ etc.

We likewise assume that $X$ is not a compound Poisson process since otherwise $\lim_{t \downarrow 0} \mathbb{P}(X_t = 0) = 1$ while the probability that $X$ leaves a small interval upwards and other quantities of interest are similarly trivial.

For $x, r, t > 0$ let

- $T_r = \{ \inf s \geq 0 : |X_s| > r \}$;
- $M_t = \sup_{s \leq t} |X_s|$;
- $\Delta_t^+ = \max_{s \leq t} \Delta X_s$ (where $\Delta X_t$ is the jump process of $X$);
- $\Delta_t^- = -\min_{s \leq t} \Delta X_s$;
- $\Delta_t = \Delta_t^+ \vee \Delta_t^-$;
- $V(x) = \Pi(x, \infty)$;
- $W(x) = \Pi(-\infty, -x)$;
- $L(x) = V(x) + W(x)$;
- $D(x) = V(x) - W(x)$;
- $A(x) = \varphi + xD(x) - 1_{\{x \leq 1\}} \int_{x < |y| \leq 1} y \Pi(dy) + 1_{\{x > 1\}} \int_{1 < |y| \leq x} y \Pi(dy)$.
\[ \varphi + D(1) - \int_x^1 D(y) \, dy; \]

\[ U(x) = 2 \int_0^x y \, L(y) \, dy; \]

\[ k(x) = \frac{|A(x)|}{x} + \frac{U(x)}{x^2}. \]

We define \( \tilde{X}^r \) as \( X \) with jumps whose moduli are larger than \( r \) reduced to size \( r \). i.e. \( \tilde{X}^r_t = X_t - \sum_{s \leq t} \Delta X_s 1_{[\Delta X_s > r]} + r \sum_{s \leq t} 1_{[\Delta X_s > r]} - r \sum_{s \leq t} 1_{[\Delta X_s < -r]} \).

By differentiating characteristic functions we can show

\[ EX_1^r = A(r); \quad \text{Var} \tilde{X}_1^r = U(r). \]  (2)

Compare the following: for \( r < 1 \)

\[ E \left( X_1 - \sum_{s \leq 1} 1_{[\Delta X_s > r]} \Delta X_s \right) = \varphi - \int_{r < |x| \leq 1} x \, \Pi(dx) = A(r) - r D(r). \]  (3)

2 Main results

**Theorem 1** The following are equivalent as \( r, t \to 0 \):

\[ \mathbb{P}(X_T > 0) \to 1; \]  (4)

\[ \mathbb{P}(X_t > 0) \to 1; \]  (5)

\[ \frac{X_{T_r}}{\Delta_{T_r}} \xrightarrow{p} \infty; \]  (6)

\[ \frac{X_t}{\Delta_t} \xrightarrow{p} \infty; \]  (7)

\[ \frac{A(r)}{r W(r)} \to \infty. \]  (8)

This result has a large time LP analogue [5], derived from a similar result for RWs [10], which states:

\[ \mathbb{P}(X_t > 0) \to 1 \Leftrightarrow \mathbb{P}(X_{T_r} > 0) \to 1 \Leftrightarrow \frac{A(r)}{\sqrt{W(r)U(r)}} \to \infty \text{ (as } r \to \infty \text{).} \]  (9)

Note that in Theorem 1 \( \frac{A(r)}{r W(r)} \to \infty \) may be replaced by \( \frac{A(r)}{\sqrt{W(r)U(r)}} \to \infty \) (or vice versa in (9).)
Moreover, Doney [4] has already proved the equivalence of (5), (7) and (8) using a direct proof that (5) is equivalent to (8) similar to the one used by Kesten and Maller [10] to prove the RW version. We proceed here, however, by first showing that (4) is equivalent to (8) using a proof similar to Griffin and McConnell [9] for the RW case, before going on to show that (4) is also equivalent to the other probabilistic conditions.

If $X$ has bounded variation (b.v.) (that is if $\sum_{t \leq 1} |\Delta X_t| < \infty$ or equivalently $\int_0^1 L(x)dx < \infty$) then the analytical condition (8) can be somewhat simplified. In this case the process can be reduced to the sum of the difference of two (pure-jump) subordinators with a drift $d$ (where $d = \lim_{r \downarrow 0} A(r)$). The $d \neq 0$ case is not of interest since we then have $Xt^{-1} \overset{a.s.}\rightarrow d$ (see [2] p. 84). If, on the other hand, $d = 0$, then we write

$$X_t = Y_t - Z_t$$

where $Y_t$ and $Z_t$ are (pure-jump) subordinators with jump measures $1_{[x>0]}\Pi(dx)$ and $1_{[x>0]}\Pi'(dx)$ respectively. Rearranging (8) then yields the following equivalent:

$$\int_0^r (V(x) - W(x)) dx \overset{rW(r)}\rightarrow \infty.$$ (10)

Moreover, it is easily deduced from (10) that for $\lambda > 0$

$$\mathbb{P}(Y_t > \lambda Z_t) \rightarrow 1 \iff \int_0^r (V(\lambda x) - W(x)) dx \overset{rW(r)}\rightarrow \infty.$$ (11)

Thus as $t,r$ go to 0 (or $\infty$) we have

$$\frac{Y_t}{Z_t} \overset{p}\rightarrow \infty \iff \int_0^r (V(\lambda x) - W(x)) dx \overset{rW(r)}\rightarrow \infty \ \forall \lambda > 0.$$ (12)

It is interesting to compare (10) with the condition for the irregularity of $(-\infty,0)$. Namely, Bertoin [3] showed that for a b.v. $X$ with zero drift then as $t \downarrow 0$

$$1_{[X_t>0]} \overset{a.s.}\rightarrow 1 \iff \frac{Y_t}{Z_t} \overset{a.s.}\rightarrow \infty \iff \int_0^1 \frac{x|W(dx)|}{\int_0^x V(y)dy} < \infty.$$ (13)

In view of Bertoin’s result it might be wondered if there are any ostensibly stronger probabilistic conditions equivalent to $\mathbb{P}(Y_t > Z_t) \rightarrow 1$. Note however that (12) is stronger than (10). In fact, the following example shows that it is possible for $\mathbb{P}(Y_t > Z_t)$ to go to one while $\mathbb{P}((1-\varepsilon)Y_t > Z_t)$ goes to zero for all $\varepsilon > 0$. 

© Springer
Example  Let
\[ V(r) = \frac{1}{r \log^2 r} \left(1 + \frac{3}{2\sqrt{\log r}}\right); \quad W(r) = \frac{1}{r \log^2 r}; \]
such that
\[ \int_0^r V(x) \, dx = \frac{1}{\log r} \left(1 + \frac{1}{\sqrt{\log r}}\right); \quad \int_0^r W(x) \, dx = \frac{1}{\log r}. \]

Then
\[ \frac{\int_0^r (V(x) - W(x)) \, dx}{r W(r)} = \sqrt{\log r} \]
and thus \( P(Y_t > Z_t) \) goes to one as \( t \) goes to 0 by (10).

Whereas for any \( \varepsilon > 0 \)
\[ \frac{\int_0^r (W(x(1-\varepsilon)) - V(x)) \, dx}{r V(r)} = \frac{(1-\varepsilon)^{-1} \int_0^r W(x) \, dx - \int_0^r V(x) \, dx}{r V(r)} \approx (1-\varepsilon)^{-1} |\log r| - |\log r| \left(1 + \frac{1}{\sqrt{|\log r|}}\right) \]
and hence \( P((1-\varepsilon) Y_t > Z_t) \) goes to zero as \( t \) goes to 0 by (11).

If \( X \) has unbounded variation (u.b.v.) (and hence is regular for both half-lines), then first note that (8) implies the prevalence of negative jumps in the sense that
\[ \liminf_{r \downarrow 0} A(r) \geq 0. \quad (13) \]
As we are now assuming \( \int_0^1 W(x) \, dx = \infty \) the analytical condition (8) further requires that
\[ \lim_{r \downarrow 0} \frac{\int_r^1 W(x) \, dx}{r W(x)} = \infty. \]
Thus \( \int_r^1 W(x) \, dx \) must be slowly varying at zero (by Lemma 7). Hence by the monotone density theorem \( W(r) \) is regularly varying with index \(-1\). So \( X \) is of unbounded variation but only just. (i.e. by (13) \( \int_r^1 L(x) \, dx \) goes to infinity ‘slowly’.) We may compare this with other results where more variation leads to less extreme (limiting) values of \( P(X_t > 0) \). e.g. For spectrally negative
Lévy processes, \( \mathbb{P}(X_t > 0) \to p \) is equivalent to the Laplace exponent (i.e. \(-\varphi(-i \cdot))\) regularly varying with index \( p^{-1} \) (at 0 or \( \infty \) respectively). Note that in this case \( \lim_{t \downarrow 0} \mathbb{P}(X_t > 0) \to 1 \) is equivalent to \( W(r) \) regularly varying at 0 with index \(-1\). While for a stable process with index \( \alpha \) the possible values of \( \mathbb{P}(X_1 > 0) = \lim_{t \downarrow 0} \mathbb{P}(X_t > 0) \) range over \([1 - \alpha^{-1}, \alpha^{-1}]\). (See Bertoin (1996) for more details.)

For more on conditions (6) and (7) see the comments preceding Theorem 4 below.

**Theorem 2** For \( \alpha > 0 \) the following are equivalent as \( r, t \to 0 \):

\[
\frac{X_{Tr}}{T_r^{1/\alpha}} \overset{p}{\to} \infty; \quad \frac{X_t}{t^{1/\alpha}} \overset{p}{\to} \infty; \quad \frac{A(r)}{rW(r)} \to \infty, A(r)r^{\alpha-1} \to \infty. \tag{16}
\]

Theorem 2 also provides an analogue to results at large times; see Kesten and Maller [11] for the RW case and Doney [5] who shows the equivalence of (14), (15), and (16) for \( \alpha = 1 \) as \( r, t \to \infty \). The sufficiency of (16) for (15) (as \( r, t \to 0 \)) when \( \alpha = 1 \) was first proved by Doney and Maller [6].

Similarly to above, if \( X \) has b.v. and zero drift then the analytical condition may be rewritten. i.e. (16) becomes

\[
\int_0^t V(x) - W(x) dx \rightarrow \frac{A(r)}{rW(r)} \rightarrow \infty. \tag{17}
\]

Note that for any \( \alpha \in (0, 1) \) it is easy to find processes such that (10) holds while (17) fails. Clearly if \( \alpha = 1 \) then the conditions in Theorem 2 are never satisfied for any b.v. \( X \).

If \( X \) has u.b.v. then, since (8) implies that \( rW(r) \) is slowly varying as \( r \) goes to 0, it also forces \( A(r)r^{\alpha-1} \) to go to infinity for all \( \alpha \in (0, 1) \) and hence

\[
X \text{ has u.b.v., } \mathbb{P}(X_t > 0) \to 1 \Rightarrow \frac{X_t}{t^{1/\alpha}} \overset{p}{\to} \infty \quad \forall \alpha \in (0, 1).
\]

While when \( \alpha = 1 \) we have, as \( t \) and \( r \) go to zero,

\[
\frac{X_t}{t} \overset{p}{\to} \infty \iff \frac{A(r)}{1+rW(r)} \to \infty.
\]

Whereas, since (8) implies \( A(r) \) is bounded above by a slowly varying function, (16) can never hold for \( \alpha > 1 \).

This is slightly different to what happens at infinity where no matter how large we take \( \alpha \) we can find \( X \) such that \( X_t/t^\alpha \overset{p}{\to} \infty \), while, similarly to what happens
with u.b.v. $X$ at zero, $\lim_{t \to \infty} \mathbb{P}(X_t > 0) = 1$ implies $X_t/t^\alpha \overset{p}{\rightarrow} \infty \ \forall \alpha \in (0, 1)$ (see e.g. [6]).

### 3 Sequential results

Note that the results (and comments) in this section are also valid at infinity. However, as this can be shown using simple adaptations of the arguments used below, and in keeping with the tone of the rest of the paper, we will concentrate on the small-time cases.

**Theorem 3** For any sequence $r_k \downarrow 0$ the following are equivalent:

\[
\frac{W(\lambda r_k)}{k(\lambda r_k)} \to 0 \quad \forall \lambda > 0; \quad (18)
\]

\[
\frac{\Delta^{-}_{T_{r_k}}}{r_k} \overset{p}{\rightarrow} 0; \quad (19)
\]

\[
\frac{\Delta X_{T_{r_k}} \wedge 0}{r_k} \overset{p}{\rightarrow} 0; \quad (20)
\]

\[
\frac{\Delta^{-}_{T_{r_k}}}{X_{T_{r_k}}} \overset{p}{\rightarrow} 0. \quad (21)
\]

This result is related to various earlier theorems concerning the relative magnitude of overshoots or of biggest jumps at exit times. Indeed, in the full-sequence case it may be seen as a simpler small-time one-sided analogue to a result (Theorem 2.1) from Griffin and Maller [7], which gives an analytical condition equivalent to $|S_T| r^{-1} \overset{p}{\rightarrow} 1$ as $r \to \infty$ for a RW $S$. The interesting thing about Theorem 3, however, is that it is in strict sequential form, in which case it turns out to be appropriate to study relations relative to the size of the jump at $T_{r_k}$ rather than to $X_{T_{r_k}}$. (i.e. We consider when $\frac{\Delta r_k}{r_k} \overset{p}{\rightarrow} 0$ rather than when $\frac{|X_{T_{r_k}}|}{r_k} \overset{p}{\rightarrow} 1$ etc.)

Indeed, it is possible to have $X_{T_{r_k}}/r_k \overset{p}{\rightarrow} 0$ but not $\Delta X_{T_{r_k}}/r_k \overset{p}{\rightarrow} 0$. For example, we may construct a pure-jump subordinator $X$ and a sequence $r_k \downarrow 0$ such that (with high probability) $X$ jumps over the small $r_k$ with a jump of size $(k + 1)r_k/k$ before the sum of the smaller jumps has reached $r_k/k$. Moreover, this example is typical in the sense that it can be shown by reasonings very similar to those used in the proof of (step 2 of) Theorem 3 below that if we have $X_{T_{r_l}}/r_l \overset{p}{\rightarrow} 1$ but there exists $\varepsilon > 0$ such that $\mathbb{P}(\Delta X_{T_{r_l}}/r_l > \varepsilon) > 0$ then $X$ is ‘mesh-jumping’ relative to $r_l$: that is, for a subsequence $r_l$ of $r_k$, with probability approaching one as $l$ gets large, $X$ is confined to a set of small (relative to $r_l$) intervals before $T_{r_l}$, neighbouring intervals being separated by a distance close to a divisor $d_l(> 1/\varepsilon)$ of $r_l$ (imagine the rungs of a ladder). Consider the subordinator $X$ and sequence $r_k$ in the example above, and note that if we take...
any bounded sequence of integers \( n_k \) then we similarly have \( X_{T_{n_k} r_k} / n_k r_k \overset{p}{\to} 1 \) while \( \Delta X_{T_{n_k} r_k} / n_k r_k \not\overset{p}{\to} 0 \).

This in turn explains why \( X \) cannot be weakly stable \((X_T, r^{-1} \overset{p}{\to} 1)\) and have big jumps (in the sense that \( \Delta_T r^{-1} \not\overset{p}{\to} 0 \)).

It is an immediate consequence of Theorem 3 that \( \mathbb{P}(X_{T_{r_k}} > 0) \to 1 \) implies \( X_{T_{r_k}} / \Delta_{T_{r_k}} \overset{p}{\to} \infty \). This may be loosely justified as follows: if \( \mathbb{P}(X_{T_{r_k}} < N \Delta_{T_{r_k}}) \) (or \( \mathbb{P}(X_{t_k} < N \Delta_{t_k}) \)) is bounded away from 0 then we could reason that, since \( X \) has stationary, independent increments, it could have \( N \) such jumps before \( T_{r_k} \) (or \( t_k \)) with probability bounded away from 0.

An argument of this kind can be formalised for \( X_{t_k} \), whence we have the following Theorem.

**Theorem 4**

(i) For any sequence \( r_k \downarrow 0 \), \( \mathbb{P}(X_{T_{r_k}} > 0) \to 1 \iff \frac{X_{T_{r_k}}}{\Delta_{T_{r_k}}} \overset{p}{\to} \infty \).

(ii) For any sequence \( t_k \downarrow 0 \), \( \mathbb{P}(X_{t_k} > 0) \to 1 \iff \frac{X_{t_k}}{\Delta_{t_k}} \overset{p}{\to} \infty \).

We give an analytical condition that the probability a LP \( X \) leaves a sequence of intervals \([-r_k, r_k]\) approaches one. The proof is similar to that for Griffin and McConnell’s [9] analogous result for the RW case.

**Theorem 5** For any sequence \( r_k \downarrow 0 \),

\[
\mathbb{P}(X_{T_{r_k}} > 0) \to 1 \iff \liminf_{r_k \downarrow 0} \frac{A(\lambda r_k)}{\lambda r_k k(\lambda r_k)} > 0, \quad \frac{W(\lambda r_k)}{k(\lambda r_k)} \to 0 \quad \forall \lambda > 0.
\]

**4 Preliminaries and proofs**

Our approach will be to first prove the sequential results of Sect. 3 before going on to deduce the full-sequence results.

We will repeatedly appeal to the following theorem from Pruitt [13] (see also [6].) It is similarly crucial in the proof of the large-time results.

**Theorem 6** There exists \( C > 0 \) such that for any LP \( X \) and for all \( a, t > 0 \):

(i) \( \mathbb{P}(M_t \geq a) \leq C t k(a) \);

(ii) \( \mathbb{P}(M_t \leq a) \leq \frac{C}{t k(a)} \);

(iii) \( \frac{1}{C k(a)} \leq E T_a \leq \frac{C}{k(a)} \).

Furthermore for all \( x > 0, \lambda > 1 \)

\[
\lambda^{-3} \leq \frac{k(\lambda x)}{k(x)} \leq 3.
\]
We also require the following lemma (from e.g. [6]).

**Lemma 7** Let $f$ be any positive differentiable function such that

$$\lim_{x \downarrow 0} \frac{xf'(x)}{f(x)} = 0.$$ 

Then $f$ is slowly varying at 0.

**Proof of Theorem 3** To avoid an overabundance of minus signs later in the proof we will prove Theorem 3 for $-X$. Namely, we show that the following are equivalent (for any sequence $r_i$):

$$\frac{V(\lambda r_i)}{k(\lambda r_i)} \to 0 \quad \forall \lambda > 0;$$  

(22)

$$\frac{\Delta^+_{T_{ri}}}{r_i} \to 0;$$  

(23)

$$\frac{\Delta^+_{X_{T_{ri}}}}{r_i} \to 0;$$  

(24)

$$\frac{\Delta^+_{\lambda_{ri}}}{\lambda_{ri}} \to 0 \quad \forall \lambda > 0;$$  

(25)

$$\frac{\Delta_{X_{\lambda_{ri}}}}{\lambda_{ri}} \to 0 \quad \forall \lambda > 0.$$  

(26)

We let

$$Y'_t = \sum_{0 \leq s \leq t} \mathbf{1}_{\{X_t > r_i\}}.$$  

(27)

Given $\varepsilon > 0$ we have

$$\mathbb{P}(\Delta^+_{T_{\lambda r_i}} > \lambda r_i \varepsilon) \leq E(Y_{T_{\lambda r_i}}^{\lambda r_i \varepsilon})$$  

$$\leq EY_{1}^{\lambda r_i \varepsilon} ET_{\lambda r_i}$$  

$$\leq c \frac{EY_{1}^{\lambda r_i \varepsilon}}{k(\lambda r_i \varepsilon)}$$  

$$\leq c \frac{V(\lambda r_i \varepsilon)}{k(\lambda r_i \varepsilon)},$$

where the second inequality follows by Optional Stopping and the third from Theorem 6. ((26)⇒(27))

$$\Delta^+_{T_{\lambda r_i}} \geq \Delta_{X_{T_{\lambda r_i}}} \lor 0.$$  

(27)
\((27) \Rightarrow (22)\) Since \(\{\Delta X_{T_{\lambda r_i}} \vee 0 > 3\lambda r_i/2\}\) implies \(\{\Delta X_{T_{\lambda r_i}} \vee 0 > 3\lambda r_i/2\}\) we have

\[
\mathbb{P}(\Delta X_{T_{\lambda r_i}} \vee 0 > \lambda r_i) \geq \mathbb{P}(\Delta X_{T_{\lambda r_i}} \vee 0 > 3\lambda r_i/2) \\
= E(Y^{3\lambda r_i/2}_{T_{\lambda r_i}/2}) \\
= EY^1_{\lambda r_i/2}ET_{\lambda r_i/2} \\
\geq c \frac{V(3\lambda r_i/2)}{k(3\lambda r_i/2)},
\]

where we have again used Optional Stopping and Theorem 6. Hence we have shown that \((22), (26)\) and \((27)\) are equivalent.

We have trivially that

\[
\Delta \lambda T \frac{r_i}{\lambda r_i} \rightarrow 0 \quad \forall \lambda > 0 \Rightarrow \Delta \frac{r_i}{\lambda r_i} \rightarrow 0 \Rightarrow \Delta \frac{r_i}{\lambda r_i} \rightarrow 0 \geq P 0.
\]

i.e. \((26) \Rightarrow (23) \Rightarrow (24)\). Since, given \(\lambda > 0\), \(\frac{\Delta T_{\lambda r_i}}{\lambda r_i} \leq \frac{1}{\lambda} \frac{\Delta T_{2n r_i}}{r_i} \) for \(n\) large enough, ‘\((24) \Rightarrow (26)\)’ (and hence the equivalence of \((26), (23), (24)\)) would follow if we could show that

\[(24) \Rightarrow \Delta \frac{T_{2r_i}}{r_i} \rightarrow P 0. \quad (28)\]

We will prove \((28)\) in the following two steps:-

Step 1: RHS (of \((28)\)) fails \(\Rightarrow \exists n \in \mathbb{N}\) s.t. \(\Delta \frac{T_{r_i/2}}{r_i} \rightarrow P 0;\)

Step 2: \(\Delta \frac{T_{r_i}}{r_i} \rightarrow P 0 \Rightarrow \Delta \frac{T_{2n r_i}}{r_i} \rightarrow P 0.\)

Thus, the failure of the RHS of \((28)\) will imply \(\frac{\Delta X_{T_{r_i/2n}} \vee 0}{r_i} \rightarrow P 0\) (by Step 1), whence we deduce (by Step 2) the failure of \((24)\).

**Proof of Step 1** Assume \(\exists \varepsilon > 0, n \in \mathbb{N}\) and \(\{r_s\} \subseteq \{r_i\}\) such that

\[
\mathbb{P}\left(\Delta \frac{T_{2r_i}}{2^n} > \frac{r_s}{2^n}\right) > \varepsilon
\]

for all \(r_s\).

For all \(s\), let

\[
\tau_0^s = 0; \tau_j^s = \inf\left(t > \tau_{j-1}^s : \left|X_t - X_{\tau_{j-1}^s}\right| > r_s/2^{n+1}\right) \quad \text{for} \quad j \in \mathbb{N}.
\]
Then, for any \( s \), any \( j \),

\[
\mathbb{P} \left( \tau_{2n+4j}^s < T_{2rs} \mid \tau_{2n+4(j-1)}^s < T_{2rs} \right) \\
\leq 1 - \mathbb{P} \left( X_T > 0 \right)^{2n+4} - \mathbb{P} \left( X_T < 0 \right)^{2n+4} \\
\leq 1 - (1/2)^{2n+4}.
\]

Therefore there exists an integer \( N \) such that \( \mathbb{P}(\tau_{2n+4N}^s \leq T_{2rs}) \leq \varepsilon/2 \) for all \( s \), and hence

\[
\frac{\varepsilon}{2} \leq \mathbb{P} \left( \Delta^+_{T_{2rs}} > \frac{r_s}{2^n} \right) - \mathbb{P} \left( \tau_{2n+4N}^s \leq T_{2rs} \right) \\
\leq \mathbb{P} \left( \Delta^+_{T_{2rs}} > \frac{r_s}{2^n}, \tau_{2n+4N}^s > T_{2rs} \right) \\
\leq \mathbb{P} \left( \Delta^+_{T_{2n+4N}} > \frac{r_s}{2^n} \right) \\
\leq 2^{n+4}N \times \mathbb{P} \left( \Delta^+_{T_{2n+4N}/2n+1} > \frac{r_s}{2^n} \right).
\]

Thus

\[
\mathbb{P} \left( \Delta X_{T_{rs}/2n+1} > \frac{r_s}{2^n} \right) \geq \varepsilon/(2^{n+5}N)
\]

completing the proof of Step 1.

**Proof of Step 2** We assume for contradiction that

\[
\frac{\Delta X_{T_n}}{r_i} \not\xrightarrow{p} 0 \quad (29)
\]

and

\[
\frac{\Delta X_{T_{2n}}}{r_i} \not\xrightarrow{p} 0 \quad (30)
\]

Thus we must have either \( \{r_a\} \subseteq \{r_i\}, \lambda' > 0, \alpha' > 0 \) such that

\[
\mathbb{P} \left( X_{T_a} > (1 + \lambda')r_a \right) > \alpha' \quad \forall r_a, \quad (31)
\]

or \( \{r_b\} \subseteq \{r_i\}, \lambda'' > 0, \alpha'' > 0 \) such that

\[
\mathbb{P} \left( X_{T_{rb}} > 0, X_{T_{rb}} - < (1 - \lambda'')r_b \right) > \alpha'' \quad \forall r_b. \quad (32)
\]
If (31) holds then by the Markov property applied on entry into \([r_a(1-\lambda'/2), r_a]\) we have

\[
P \left( \Delta X_{T_{2r_a}} > \lambda' r_a/2 \right) \geq P \left( X \text{ visits } [r_a(1-\lambda'/2), r_a] \text{ before } T_{2r_a} \right) \\
\times P \left( X_{T_{r_a}} > (1+\lambda') r_a \right),
\]

and thus by (30)

\[
P \left( X \text{ visits } [r_a(1-\lambda'/2), r_a] \text{ before } T_{2r_a} \right) \to 0
\]
as \(r_a \downarrow 0\). If on the other hand (32) holds then by stopping \(X\) when it enters \([r_b, r_b(1+\lambda''/2)]\) we similarly have

\[
P \left( X \text{ visits } [r_b, r_b(1+\lambda''/2)] \text{ before } T_{2r_b} \right) \to 0,
\]

which in turn (by stopping \(X\) in \([r_b(1-\lambda''/4), r_b]\) and spotting \(\lim \inf_{r_a} P(X_{T_{2r_a}} \to 0) > 0\)) implies that

\[
P \left( X \text{ visits } [r_b(1-\lambda''/4), r_b] \text{ before } T_{2r_b} \right) \to 0.
\]

Hence in all cases (when (29) and (30) hold) we may define a positive \(d\) such that

\[
d = \sup_{\{r_s\} \subseteq \{r_i\}} \sup \{ \delta : P \left( X \text{ visits } [r_s(1-\delta), r_s] \text{ before } T_{2r_s} \right) \to 0 \}.
\]

Now choose \(\varepsilon < 1/50\), \(\{r_s\} \subseteq \{r_i\}\) and \(\xi > 0\) such that

\[
P \left( X \text{ visits } [r_s(1-d(1-\varepsilon)), r_s] \text{ before } T_{r_s} \right) \to 0 \tag{33}
\]
as \(r_s \downarrow 0\) and

\[
P \left( X \text{ visits } \left[ 0 \lor \left[ r_s(1-d(1+\varepsilon)) \right] , r_s(1-d(1-\varepsilon)) \right] \text{ before } T_{2r_s} \right) > \xi \tag{34}
\]
for all \(r_s\). Then, by stopping in \([2r_s d\varepsilon, r_s d(1-\varepsilon)]\) and considering (34) and (33), we must have

\[
P \left( X \text{ visits } [2r_s d\varepsilon, r_s d(1-\varepsilon)] \text{ before } T_{r_s} \right) \to 0. \tag{35}
\]

Consequently, stopping in \([2r_s - r_s d(1-\varepsilon), 2r_s - 2r_s d\varepsilon]\), we deduce from (30) that

\[
P \left( X \text{ visits } [2r_s - r_s d(1-\varepsilon), 2r_s - 2r_s d\varepsilon] \text{ before } T_{2r_s} \right) \to 0. \tag{36}
\]

Then, noting that,

\[
P \left( X \text{ visits } [2r_s - 2r_s d\varepsilon, 2r_s] \text{ before } T_{2r_s} \left| X_{T_{2r_s}} > 0 \right\rangle \to 1
\]

\[\copyright\] Springer
we must have
\[ P(X \text{ visits } [-r_s d(1 - \varepsilon), -2r_s d\varepsilon] \text{ before } T_{2r_s}) \to 0, \tag{37} \]
since otherwise (36) would fail. From (35) and (37) we see that the probability \( X \) leaves \([-2r_s d\varepsilon, 2r_s d\varepsilon]\) by a jump with modulus bigger than \( dr_s/2 \) goes to one as \( r_s \) goes to 0. For each \( s \) we may consider \( X \) as the sum of two independent processes \( Y^s \) and \( Z^s \) such that \( Z^s \) consists of the jumps of \( X \) with modulus bigger than \( dr_s/2 \). By (29) we may choose \( \alpha > 0 \) such that
\[ \liminf_{r_s} P(X_{T_{r_s}} > 0) > \alpha, \]
and hence we must also have a positive \( p \) such that
\[ p = \liminf_{s \to \infty} P(\text{the first jump of } Z^s \text{ is positive}) > 0. \]
Let
\[ E_s = [2r_s - r_s d\varepsilon, 2r_s] \]
such that
\[ \liminf_{r_s} P(X \text{ visits } E_s \text{ before } T_{2r_s}) \geq \liminf_{r_s} P(X_{T_{2r_s}} > 0) > \alpha^2. \]
Hence (by (30)), stopping in \( E_s \),
\[ \liminf_{s \to \infty} P(Z^s \text{ jumps before } Y^s \text{ visits } (0, \infty)) \to 0. \tag{38} \]
Thus, if we define
\[ A^s_{c_s} = P(Y^s \text{ visits } (c_s r_s, \infty) \text{ before } Z^s \text{ jumps}), \]
then for each large \( s \), there must exist \( c_s > 0 \) such that
\[ P(A^s_{c_s}) \in (1/3, 2/3); \]
to see this spot that \( P(A^s_y) \) decreases as \( y \) increases, that \( P(A^s_{2dr_s}) \) is close to 0 (by (35)), while by (38) \( \exists \chi > 0 \text{ s.t. } P(A^s_{\chi}) \) is close to one; whereas we can exclude a discontinuity bridging \((1/3, 2/3)\) since for \( x > 0 \), \( P(A^s_{2x}) > P(A^s_{x})^2 \).
As noted above we have
\[ P(X \text{ enters } E_s \text{ before } T_{2r_s} \mid X_{T_{2r_s}} > 0) \to 1, \]
and hence
\[
\liminf_{s \to \infty} \mathbb{P}(X \text{ enters } \{E_s - c_3s\} \text{ before } T_{2s}) \\
\geq \liminf_{s \to \infty} \mathbb{P}(X \text{ enters } E_s \text{ before } T_{2s} \mid A_{c_3}, X_{T_{2s}} > 0, XT_{2s} > 0) \\
\geq \liminf_{s \to \infty} \mathbb{P}(A_{c_3}, X_{T_{2s}} > 0, XT_{2s} > 0) \\
> \alpha^2/3.
\]

Thus, finally, we have
\[
\liminf_{s \to \infty} \mathbb{P}(\Delta X_{T_{2s}} > dr_2s/3) > \liminf_{s \to \infty} \mathbb{P}(X \text{ enters } \{E_s - c_3s\} \text{ before } T_{2s}) \\
\times \mathbb{P}(\text{the first } Z_s\text{-jump is } +\text{ve and occurs before } Y_s \text{ leaves } [-2s, d_c, c_3s]) \\
> \alpha^2p/9,
\]

which contradicts (30) and completes the proof of Step 2.

We complete the proof of Theorem 3 by showing the equivalence of (23) and (25).

(23) $\Rightarrow$ (25) is immediate. Now assume (23) fails. Then, by above (24) fails too and hence there exists \( \{r_j\} \subseteq \{r_i\}, \varepsilon > 0 \) and \( c > 0 \) such that \( \mathbb{P}\left(\Delta X_{T_{r_j}} / r_j > c\right) > \varepsilon \ \forall r_j \). Thus for each \( r_j \) we have that with probability greater than \( \varepsilon \)
\[
\frac{\Delta_{r_j}^+}{X_{T_{r_j}}} \geq \frac{\Delta X_{T_{r_j}}}{\Delta X_{T_{r_j}} + r_j} > \frac{1}{1 + c^{-1}}
\]

and hence (25) fails. \( \Box \)

Informally, Theorem 3 shows that if \( X \) sometimes has large negative jumps before \( T_{r_k} \) then these jumps will on occasions carry it out of the interval \([-r_k, r_k]\). Thus when we come to the question of determining when the probability that \( X \) leaves an interval upwards goes to 1 as the interval is shrunk to 0 we may exclude all processes where \( \Delta_{T_{r_k}}^+ \not\to 0 \).

Furthermore, it can be deduced from the well known fact that a simple asymmetric random walk diverges that for a LP with no negative jumps
\[
\liminf_{r \downarrow 0} \mathbb{P}(X_{T_r} > 0) = p > 1/2 \Rightarrow \mathbb{P}(X_{T_r} > 0) \to 1.
\]

Indeed, define a simple RW such that \( \mathbb{P}(S_1 = 1) = p = 1 - \mathbb{P}(S_1 = -1) > 1/2 \). We may then find \( N > 0 \) such that the probability \( S \) leaves an interval \([-N, N]\) upwards is arbitrarily close to 1. Since \( X \) has no negative overshoots
\[
\liminf_{r \downarrow 0} \mathbb{P}(X_{T_r} > 0) = \liminf_{r \downarrow 0} \mathbb{P}(X_{T_Nr} > 0) \geq \mathbb{P}(S_{T_N} > 0).
\]
It turns out that a similar reasoning can be applied in this instance, and is used in the following proof, which is similar to that used in Griffin and McConnell [9] for the RW case.

Proof of Theorem 5 First note that

\[
P(X_{T_{\delta k}} > 0) \to 1 \Rightarrow P(X_{T_{\delta k}} > 0) \to 1 \quad \forall \delta > 0, \tag{39}
\]

since if \( \delta < 1 \) then we can let \( N \) be the smallest integer \( \geq 1/\delta \) and reason via:

\[
P(X_{T_{\delta k}} < 0)^N \leq P(X_{T_{\delta k}} < 0);
\]

whereas if \( \delta \geq 1 \) then for any integer \( N \geq \delta \) we have

\[
P(X_{T_{\delta k}} > 0) \geq P(X_{T_{\delta k}} > 0)^N.
\]

Recall that we defined \( \tilde{X}_t^{\lambda r_k}, t \geq 0 \) as \( X \) with all jumps whose modulus is bigger than \( \lambda r_k \) being reduced to a size of \( \lambda r_k \). In other words we adjust the jump measure as follows:

\[
\tilde{W}(x) = W(x), \quad \tilde{V}(x) = V(x) \quad \text{for} \ x < \lambda r_k;
\]

\[
\tilde{W}(x) = 0, \quad \tilde{V}(x) = 0 \quad \text{for} \ x \geq \lambda r_k.
\]

Let

\[
Y_t = \tilde{X}_t^{\lambda r_k} - E \tilde{X}_1^{\lambda r_k} t.
\]

As \( Y \) is a (well-behaved) martingale and \( \tilde{T}_{r_k} \) a stopping time (the first time the process \( \tilde{X} \) leaves the interval \([-r_k, r_k]\)), we have from Optional Stopping that

\[
E \tilde{X}_{\tilde{T}_{r_k}}^{\lambda r_k} = E \tilde{X}_1^{\lambda r_k} E \tilde{T}_{r_k}.
\]

Moreover

\[
E \tilde{X}_{\tilde{T}_{r_k}}^{\lambda r_k} \geq r_k P(\tilde{X}_{\tilde{T}_{r_k}}^{\lambda r_k} > 0) - (\lambda + 1)r_k P(\tilde{X}_{\tilde{T}_{r_k}}^{\lambda r_k} < 0)
\]

\[
\geq (\lambda + 2)r_k P(\tilde{X}_{\tilde{T}_{r_k}}^{\lambda r_k} > 0) - (\lambda + 1)r_k;
\]

while by similar reasoning

\[
E \tilde{X}_{\tilde{T}_{r_k}}^{\lambda r_k} \leq (\lambda + 2)r_k P(\tilde{X}_{\tilde{T}_{r_k}}^{\lambda r_k} > 0) - r_k.
\]
Hence
\[
\frac{E \hat{X}_1^{\lambda r_k} E \hat{T}_{r_k} r_k^{-1} + \lambda + 1}{\lambda + 2} \geq P(\hat{X}_1^{\lambda r_k} > 0) \geq \frac{E \hat{X}_1^{\lambda r_k} E \hat{T}_{r_k} r_k^{-1} + 1}{\lambda + 2} \tag{40}
\]

If we set \( \lambda = 2 \) then (since any jump with modulus greater than \( 2r_k \) occurring before \( T_{r_k} \) will carry \( X \) out of \([-r_k, r_k]\)) \( \hat{T}_{r_k} = T_{r_k} \) and \( \{\hat{X}_{T_{r_k}} > 0\} = \{X_{T_{r_k}} > 0\} \). Therefore, by (40), Theorem 6 and (2)
\[
P(X_{T_{r_k}} > 0) \leq \frac{1}{4} E \hat{X}_1^{2r_k} E T_{r_k} r_k^{-1} + \frac{3}{4} \leq c \frac{A(2r_k)}{r_k k(2r_k)} + \frac{3}{4}. \tag{41}
\]

And so then by (39) and Theorem 3

\[
\text{LHS}(\text{of theorem}) \Rightarrow \left(\Delta X_{T_{r_k}} \wedge 0\right) r_k^{-1} \overset{p}{\longrightarrow} 0, \ P(X_{T_{\beta r_k}} > 0) \to 1 \ \forall \beta > 0 \\
\Rightarrow \text{RHS}.
\]

We now assume RHS and will proceed from (40) to show that
\[
\lim_{\lambda \downarrow 0} \lim_{r_k \downarrow 0} \mathbb{P}(\hat{X}_1^{\lambda r_k} > 0) = 1 \tag{42}
\]
from whence we will immediately have LHS since then by Theorem 3
\[
\lim_{\lambda \downarrow 0} \lim_{r_k \downarrow 0} \mathbb{P}(\hat{X}_1^{\lambda r_k} > 0) \leq \lim_{\lambda \downarrow 0} \lim_{r_k \downarrow 0} \left[ \mathbb{P}(X_{T_{r_k}} > 0) + \mathbb{P}(\Delta_{T_{r_k}} \geq \lambda r_k) \right] \\
\leq \lim_{r_k \downarrow 0} \mathbb{P}(X_{T_{r_k}} > 0).
\]

Given \( \lambda \leq 1/2 \), define for all \( r_k \):
\[
\tau_0^{\lambda r_k} = 0; \quad \tau_{j+1}^{\lambda r_k} = \inf\{t > \tau_j^{\lambda r_k} : |X_t - X_{\tau_j}| > \lambda r_k\} \text{ for } j = 0, 1, 2, \ldots
\]

Then, for any integer \( n \), \( |\hat{X}_n^{\lambda r_k}| \leq 2n\lambda r_k \) and hence if we let \( s(\lambda) \) be the largest integer less than \( 1/2\lambda \), \( \tilde{T}_{r_k} \geq \tau_{s(\lambda)}^{\lambda r_k} \). Thus
\[
E \tilde{T}_{r_k} \geq E \tau_{s(\lambda)}^{\lambda r_k} = s(\lambda) E \tau_{s(\lambda)}^{\lambda r_k}
\]
and so
\[
3\lambda E \tilde{T}_{r_k} \geq ET_{\lambda r_k}.
\]
Then by (40), Theorem 6 and (2) we have

\[ \mathbb{P}(\hat{X}_{\lambda r_k} > 0) \geq \frac{cA(\lambda r_k)/\lambda r_k k(\lambda r_k) + 1}{\lambda + 2}. \]  

Replacing \( r_k \) with \( \delta r_k \) and \( \lambda \) with \( \lambda\delta \) we have for \( \delta > 0, \lambda \leq \delta/2 \)

\[ \mathbb{P}\left(\hat{X}_{\lambda r_k} > 0\right) \geq \frac{c_1 A(\lambda r_k)/\lambda r_k k(\lambda r_k) + 1}{\lambda \delta^{-1} + 2}. \]

Thus \( \exists p_1 > 1/2 \) such that \( \forall \delta > 0 \)

\[ \lim \liminf_{\lambda \downarrow 0, r_k \downarrow 0} \mathbb{P}(\hat{X}_{\lambda r_k} > 0) \geq p_1 \quad (44) \]

As alluded to above, if we consider the Simple Random Walk \( \{S_n, n \in \mathbb{N}\} \) with parameter \( p_1 \) (i.e. \( \mathbb{P}(S_1 = 1) = p_1, \mathbb{P}(S_1 = -1) = 1 - p_1 \) then \( \mathbb{P}(S_{T_n} > 0) \to 1 \) as \( n \to \infty \). (We are taking \( T_N \) for a RW as the first time it leaves \([-N, N]\).)

Hence for \( \varepsilon > 0 \) we may choose \( N, H \in \mathbb{N} \) such that

\[ \mathbb{P}(S_{T_N} > 0, T_N \leq H) > 1 - \varepsilon. \]

For given \( \lambda, r_k \) let \( R_n \) be a simple RW such that \( R_1 \) has the same distribution as \( \hat{X}_{\lambda r_k} \big| \hat{X}_{\lambda r_k/2N} \big|^{-1} \). Then

\[ \mathbb{P}\left(\hat{X}_{\lambda r_k} \text{ leaves } [-r_k/2 - \lambda r_k H, r_k/2 - \lambda r_k H] \text{ upwards} \right) \]
\[ \geq \mathbb{P}(R_{T_N^R} > 0, T_N^R \leq H) \]
\[ \geq \mathbb{P}(S_{T_N^S} > 0, T_N^S \leq H) \geq 1 - \varepsilon. \]

Therefore for any \( \xi > 0 \)

\[ \lim \liminf_{\lambda \downarrow 0, r_k \downarrow 0} \mathbb{P}(\hat{X}_{\lambda r_k} \text{ leaves } [-r_k(1/2 + \xi), r_k(1/2 - \xi)] \text{ upwards}) \geq 1 - \varepsilon, \]

which implies \( \lim_{\lambda \downarrow 0} \liminf_{r_k \downarrow 0} \mathbb{P}(\hat{X}_{\lambda r_k} > 0) \geq (1-\varepsilon)^2 \) and as epsilon is arbitrary (42) follows and the proof is complete. \( \square \)

**Proof of Theorem 4** (i) First note that

\[ \text{RHS} \Rightarrow \mathbb{P}(X_{T_k} > \Delta^-_{T_k}) \to 1 \Rightarrow \text{LHS}, \]

while the converse follows from Theorem 3 as

\[ \mathbb{P}(X_{T_k} > 0) \to 1 \Rightarrow (-\Delta X_{T_k} \wedge 0)/r_k \overset{p}{\to} 0 \Rightarrow \Delta^-_{T_k}/r_k \overset{p}{\to} 0. \]
We then have \( \left| X_{T_{rk}} \right| / \Delta_{T_{rk}} \xrightarrow{P} \infty \) and hence \( X_{T_{rk}} / \Delta_{T_{rk}} \xrightarrow{P} \infty \) from LHS.

(ii) RHS \( \Rightarrow \) LHS is again immediate. To prove the converse we assume for contradiction that \( \exists t_j \downarrow 0, k \in \mathbb{N} \) and \( \varepsilon > 0 \) such that

\[
\lim_{t_j} \Pr(X_{t_j} > 0) = 1 \quad \text{and} \quad \Pr(X_{t_j} < 2k\Delta_{t_j}^{-}) > 8\varepsilon \quad \text{for all } t_j. \tag{45}
\]

Let

\[
E_j = \{X_{t_j} < 2k\Delta_{t_j}^{-}\};
\]

and for each \( t_j \) choose \( c_j \) such that

\[
\Pr(E_j, \Delta_{t_j}^{-} \leq c_j) \geq 2\varepsilon \tag{46}
\]

and

\[
\Pr(E_j, \Delta_{t_j}^{-} \geq c_j) \geq 6\varepsilon. \tag{47}
\]

Then (by (47)) we must have either a subsequence \( \{t_m, c_m, E_m\} \in \{t_j, c_j, E_j\} \) such that

\[
\Pr(E_m, \Delta_{t_m}^{-} > 2c_m) \geq 2\varepsilon \quad \forall m \tag{48}
\]

or a subsequence \( \{t_n, c_n, E_n\} \in \{t_j, c_j, E_j\} \) such that

\[
\Pr(E_n, c_n \leq \Delta_{t_n}^{-} \leq 2c_n) \geq 4\varepsilon \quad \forall n. \tag{49}
\]

First assume that (48) holds and for each \( m \) let

\[
X_t = Y_t^m + Z_t^m
\]

where \( Z_t^m \) consists of all the jumps smaller than \(-2c_m\) by time \( t \). (i.e. \( Z_t^m = \sum_{0 \leq s \leq t} \Delta X_s 1_{\{\Delta X_s < -2c_m\}} \).) Further let

\[
N_t^m = \sum_{0 \leq s \leq t} 1_{\{\Delta X_s < -2c_m\}},
\]

the number of jumps of \( Z_t^m \) by time \( t \). Then since we have \( \Pr(N_{t_m}^m \geq 1) \geq 2\varepsilon \) (from (48)) and \( \Pr(N_{t_m}^m = 0) \geq 2\varepsilon \) (from (46)) the parameters, say \( p_m \), of the Poisson distributions \( N_{t_m}^m \) must be bounded uniformly away from 0 and \( \infty \) for all \( m \). Therefore \( \exists \xi > 0 \) such that for all large \( m \)

\[
\Pr(N_{t_m}^m \geq k) > e^{-p_m} p_m^k / k! > \xi.
\]

From (45) and (46)

\[
\Pr(Y_{t_m}^m \in (0, 2kc_m), Z_{t_m}^m = 0) > \varepsilon
\]
for all large $m$ and as $Y_{tm}^m$ and $Z_{tm}^m$ are independent we have (for all large $m$)

$$
P \left( X_{tm} < 0 \right) \geq P \left( Y_{tm}^m \in (0, 2kc_m), N_{tm}^m \geq k \right)
= P \left( Y_{tm}^m \in (0, 2kc_m) \right) P \left( N_{tm}^m \geq k \right)
> \varepsilon \xi,
$$

which gives the required contradiction (when (48) holds).

If on the other hand (49) holds then we now let $X_t = Y_t^n + Z_t^n$ where

$$Z_t^n = \sum_{0 \leq s \leq t} \Delta X_s 1_{\{\Delta X_s \leq -cn\}}$$

and define

$$N_t^n = 1_{\{\Delta X_s \leq -cn\}}.$$

By (45) and (49) we then have for all large $n$

$$3 \varepsilon < P \left( X_{tn} \in (0, 4ck_n), \Delta_{tn}^- \geq cn \right)
= \sum_{\alpha = 1}^{\infty} P \left( 0 < Y_{tn}^n + Z_{tn}^n < 4kc_n, N_{tn}^n = \alpha \right)
= \sum_{\alpha = 1}^{\infty} P \left( -Z_{tn}^n < Y_{tn}^n < 4kc_n - Z_{tn}^n \mid N_{tn}^n = \alpha \right) P \left( N_{tn}^n = \alpha \right).$$

Similarly to above, each $N_{tn}^n$ has a Poisson distribution with parameter say $p_n$ (where $p_n = t_n \Pi (\varnothing, -\infty, -cn]$). Since for all $n$ $P \left( N_{tn}^n \geq 1 \right) \geq 4 \varepsilon$ the $p_n$ must be uniformly bounded away from 0. (i.e. $\lim \inf_n p_n > 0$.) For the moment we will assume that they are also uniformly bounded away from infinity. Thus we may choose $C \in \mathbb{N}$ and $\xi > 0$ such that for all $n$

$$P \left( N_{tn}^n > C \right) < \varepsilon \quad \text{and} \quad \frac{P \left( N_{tn}^n = \alpha + 4k \right)}{P \left( N_{tn}^n = \alpha \right)} = \frac{p_n^{4k \alpha} \alpha!}{(\alpha + 4k)!} > \xi \quad \forall \alpha \leq C.$$

Thus, as $Y_{tn}^n$ and $Z_{tn}^n$ are independent, we have for all large $n$

$$P \left( X_{tn} < 0 \right) > \sum_{\alpha = 1}^{C} P \left( -Z_{tn}^n < Y_{tn}^n < 4kc_n - Z_{tn}^n \mid N_{tn}^n = \alpha \right) P \left( N_{tn}^n = \alpha + 4k \right)
> \sum_{\alpha = 1}^{C} P \left( -Z_{tn}^n < Y_{tn}^n < 4kc_n - Z_{tn}^n \mid N_{tn}^n = \alpha \right) \frac{P \left( N_{tn}^n = \alpha + 4k \right)}{P \left( N_{tn}^n = \alpha \right)}
> 2 \varepsilon \xi,$$
which gives a contradiction (under the assumption that \( \limsup_n p_n < \infty \).) Thus we may now suppose without loss of generality that \( p_n \to \infty \). But then

\[
\sup_{m \in \mathbb{N}} \mathbb{P}(N_{tn}^n \in [m, m + 4k]) \to 0 \quad \text{as} \quad n \to \infty.
\]

Therefore (by (45) and (49)) for all large \( n \) there exists \( H_n \in \mathbb{N} \) such that

\[
\mathbb{P}(X_{tn} \in (0, 4kc_n), N_{tn}^n \in [1, H_n]) > \varepsilon, \quad \mathbb{P}(N_{tn}^n > H_n + 4k) > \varepsilon,
\]

and hence

\[
\mathbb{P}(X_{tn} < 0) \geq \mathbb{P}(X_{tn} \in (0, 4kc_n) | N_{tn}^n \leq H_n) \mathbb{P}(N_{tn}^n > H_n + 4k) > \varepsilon^2
\]

for all large \( n \), which completes the proof. \( \Box \)

We now move on to the relation between the probability \( X \) is positive at small times and the probability \( X \) leaves small intervals upwards. We use a proof similar to that used by Kesten and Maller [11] to prove the analogous result for RW.

**Proposition 8**

(i) \( \limsup_{t \downarrow 0} \mathbb{P}(X_t > 0) = 1 \iff \limsup_{r \downarrow 0} \mathbb{P}(X_{Tr} > 0) = 1 \).

(ii) \( \lim_{t \downarrow 0} \mathbb{P}(X_t > 0) = 1 \iff \lim_{r \downarrow 0} \mathbb{P}(X_{Tr} > 0) = 1 \).

(iii) For \( \alpha > 0 \), \( X_{t/\alpha} \xrightarrow{p} \infty \) as \( t \downarrow 0 \iff X_{Tr}_{\alpha} \xrightarrow{p} \infty \) as \( r \downarrow 0 \).

**Proof** Recall that we have assumed that \( X \) is not a compound Poisson process and so

\[
\mathbb{P}(X_t = 0) = 0 \quad \forall t > 0; \quad \lim_{r \downarrow 0} k(r) = \infty.
\]

Choose large \( l > 0 \), and then for each \( r > 0 \) define

\[
t(r) = \frac{l}{k(r)}.
\]

Note that \( t(r) \to 0 \) (continuously) as \( r \downarrow 0 \) and so

\[
\liminf_{s \downarrow 0} \mathbb{P}(X_s > 0) = \liminf_{r \downarrow 0} \mathbb{P}(X_{t(r)} > 0).
\]

By Theorem 6 we have \( C > 0 \) such that

\[
\mathbb{P}\left(\frac{t(r)}{k} \leq Tr \leq t(r)\right) \geq 1 - \mathbb{P}(M_{1/k(r)} \geq r) - \mathbb{P}(M_{1/k} \leq r) \\
\geq 1 - 2C/l.
\]

\( \Box \) Springer
For \( r > 0 \) we let

\[
\tau'_0 = 0; \quad \tau'_j = \inf \left\{ s > \tau'_{j-1} : \left| X_s - X_{\tau'_{j-1}} \right| > r \right\} \quad \text{for} \ j \in \mathbb{N}.
\]

**Proof of (i) and (ii)** For \( \forall r > 0 \), applying the Markov property

\[
\mathbb{P}(X_{t(r)} \leq 0) \geq \mathbb{P}\left( X_{\tau'_{j+1}} - X_{\tau'_j} \leq -r, \ \forall j \leq l^2 - 1, \ \tau'_1 \leq t(r) \leq \tau'_{l^2} \right)
\]

\[
\geq \left( \mathbb{P}\left( \frac{t(r)}{l^2} \leq \tau'_1 \leq t(r), \ X_{\tau'_1} \leq -r \right) \right)^{l^2}
\]

\[
\geq \left( \left[ \mathbb{P}(X_T < 0) - 2C/l \right] \lor 0 \right)^{l^2} \quad \text{by (50)}.
\]

Hence

\[
\liminf_{r \downarrow 0} \mathbb{P}(X_{t(r)} \leq 0) = 0 \Rightarrow \liminf_{r \downarrow 0} \mathbb{P}(X_T < 0) \leq 2C/l,
\]

\[
\liminf_{r \downarrow 0} \mathbb{P}(X_{t(r)} \leq 0) = 0 \Rightarrow \lim_{r \downarrow 0} \mathbb{P}(X_T < 0) \leq 2C/l
\]

and since \( l \) is arbitrary we have ‘(\( \Rightarrow \))’ for (i) and (ii).

Similarly to above we have

\[
\mathbb{P}(X_{t(r)} \geq 0) \geq \mathbb{P}\left( X_{\tau'_{j+1}} - X_{\tau'_j} \geq r \text{ for all } j \leq 2l^2, \ \tau'_1 \leq t(r) \leq \tau'_{2l^2} \right)
\]

\[
\geq \mathbb{P}(X_T > 0)^{2l^2} - \mathbb{P}(\tau_{2l^2} < t(r)).
\]

Now, letting \( Z(n, p) \) be a random variable with binomial distribution \( B(n, p) \),

\[
\mathbb{P}(\tau_{2l^2} < t(r)) \leq \mathbb{P}\left( \sum_{j=1}^{2l^2} \mathbf{1}\{\tau_{j+1} - \tau_j \geq t(r)l^{-2}\} \leq l^2 \right)
\]

\[
= \mathbb{P}\left( Z(2l^2, \mathbb{P}(T_r < t(r)l^{-2})) \geq l^2 \right)
\]

\[
\leq \mathbb{P}(Z(2l^2, CL^{-1}) \geq l^2).
\]

And thus by Chebyshev’s inequality

\[
\mathbb{P}(\tau_{2l^2} < t(r)) \leq \frac{2C}{l^3} + \frac{4C^2}{l^2} \leq \frac{C_1}{l},
\]

and ‘(\( \Leftarrow \))’ follows trivially.
Proof of (iii) Assume RHS (and hence by (ii) that \( \lim_{s \downarrow 0} \mathbb{P}(X_s > 0) = 1 \)). Thus for given \( K > 0 \), we have by (50) and the strong Markov property

\[
\liminf_{s \downarrow 0} \mathbb{P}(X_s > Ks^\alpha) \geq \liminf_{r \downarrow 0} \mathbb{P}(X_{t(r)} > Kt(r)^\alpha)
\]

\[
\geq \liminf_{r \downarrow 0} \mathbb{P}(X_{T_r} > Kr^{2\alpha} T_r^\alpha, t(r)l^{-2})
\]

\[
\leq T_r \leq t(r), X_{t(r)} - X_{T_r} > 0)
\]

\[
\geq \liminf_{r \downarrow 0} \mathbb{P}(X_{t(r)} > Kr^{2\alpha} T_r^\alpha - 2C/l)
\]

\[
\geq 1 - 2C/l,
\]

and LHS follows as \( l \) is arbitrary.

Now assume LHS. For given \( K > 0 \), \( l \in \mathbb{N} \) and any \( t > 0 \) we have

\[
\mathbb{P}(X_{t(r)} \leq Kt(r)^\alpha) \geq \mathbb{P}({E_1} \cap {E_2})
\]

where

\[
{E_1} = \{0 \leq X_{\tau_j} - X_{\tau_{j-1}} \leq K(\tau_j - \tau_{j-1})^\alpha \text{ for } j = 1, 2, \ldots, l^2\};
\]

\[
{E_2} = \{t(r)l^{-2} \leq \tau_j - \tau_{j-1} \leq t(r) \text{ for } j = 1, 2, \ldots, l^2\}.
\]

Thus

\[
\limsup_{r \downarrow 0} (\mathbb{P}(0 \leq X_{T_r} \leq KT_r^\alpha) - 2C/l)^{l^2} \leq 0,
\]

and RHS follows easily. \( \Box \)

Proof of Theorem 1 The equivalence of (4), (5), (6) and (7) is immediate from Theorem 4 and Proposition 8. From Theorem 5 and (41) we have

\[
(4) \iff \liminf_{r \downarrow 0} \frac{A(r)}{rk(r)} > 0, \quad \lim_{r \downarrow 0} \frac{W(r)}{k(r)} = 0.
\]

It thus remains to show that

\[
\lim_{r \downarrow 0} \frac{A(r)}{rW(r)} = \infty \iff \lim_{r \downarrow 0} \frac{W(r)}{k(r)} = 0, \quad \liminf_{r \downarrow 0} \frac{A(r)}{rk(r)} > 0. \quad (51)
\]

Assume RHS (of (51)). Then LHS follows easily as

\[
\lim_{r \downarrow 0} \frac{A(r)}{rW(r)} = \lim_{r \downarrow 0} \frac{k(r) A(r)}{W(r) rk(r)} = \infty.
\]
Now assume LHS (of (51)). First note that
\[ \lim_{r \downarrow 0} \frac{W(r)}{k(r)} = 0. \]

Then since \( \lim_{r \downarrow 0} \frac{A(r)}{rW(r)} = \infty \) implies \( A(r) > 0 \) for small \( r \) we have
\[ \liminf_{r \downarrow 0} \frac{A(r)}{rk(r)} > 0 \quad \text{iff} \quad \limsup_{r \downarrow 0} \frac{U(r)}{rA(r)} < \infty. \] (52)

For any \( \varepsilon > 0 \) we have \( \varepsilon A(x) > xW(x) \) for all small \( x \). Thus, given \( \varepsilon \), we have (for small \( r \))
\[
\begin{align*}
\int_0^r xW(x)dx & \leq \varepsilon \int_0^r A(x)dx \\
& \leq \varepsilon \left( r\varphi + rD(1) - \int_0^r \int_0^1 D(y)dydx \right) \\
& \leq \varepsilon \left( r\varphi + rD(1) - \int_0^y \int_0^1 D(y)dydx - \int_0^r \int_0^1 D(y)dydx \right) \\
& \leq \varepsilon rA(r) - \varepsilon \int_0^r yV(y)dy + \varepsilon \int_0^r yW(y)dy. \quad \text{(53)}
\end{align*}
\]

Thus
\[
\int_0^r xW(x)dx(1 - \varepsilon)\varepsilon^{-1} \leq rA(r).
\]

Furthermore, setting \( \varepsilon = 1 \) in (53), we see that
\[ \int_0^r xV(x)dx \leq rA(r). \]

Hence we must have \( c > 0 \) such that for small \( r \)
\[ U(r)/2 = \int_0^r x(W(x) + V(x))dx \leq crA(r). \]
\[ \square \]
Before proving Theorem 2 we need the following Lemma.

**Lemma 9** For $\alpha > 0$ the following are equivalent as $r_n \downarrow 0$:

- $\frac{M_{r_n^{\alpha}}}{r_n} \xrightarrow{p} \infty$;  
- $r_n^{\alpha} k(r_n) \to \infty$;  
- $\frac{r_n^{\alpha}}{T_{r_n}} \xrightarrow{p} \infty$.  

**Proof** ($\text{(54) } \Rightarrow \text{(55)}$) For any $K \in \mathbb{N}$ we have

$$\mathbb{P}(M_{r_n^{\alpha}} \geq K r_n) \to 1,$$

which implies

$$\mathbb{P}(M_{r_n^{\alpha}/K} \geq r_n) \to 1,$$

and hence

$$\liminf_{r_n} CK^{-1} r_n^{\alpha} k(r_n) \geq 1$$

by Theorem 6.

($\text{(55) } \Rightarrow \text{(56)}$) Assume (56) fails. Then $\exists p, K > 0$ and $\{r_m\} \in \{r_n\}$ such that for all $r_m$

$$p \leq \mathbb{P}(r_m^{\alpha}/T_{r_m} < K) \leq \mathbb{P}(M_{r_m^{\alpha}/K} \leq r_m) \leq \frac{CK}{r_m^{\alpha} k(r_m)}.$$

Thus

$$\liminf_{r_n} r_n^{\alpha} k(r_n) \leq CK/p$$

and so (55) also fails.

($\text{(56) } \Rightarrow \text{(54)}$) Given $K \in \mathbb{N}$ we have $\mathbb{P}(T_{r_n} < r_n^{\alpha}/K) \to 1$. Thus $\mathbb{P}(M_{r_n^{\alpha}/K} > r_n) \to 1$ and hence $\mathbb{P}(M_{r_n^{\alpha}} > r_n K) \to 1$.  

\[\square\]

**Proof of Theorem 2** We have ‘(14) $\Leftrightarrow$ (15)’ from Proposition 8.

Assume that (16) holds. But then as $A(r)r^{\alpha-1} \to \infty$ implies $r^{\alpha} k(r) \to \infty$ we have $rT_{r}^{-1/\alpha} \xrightarrow{p} \infty$ from Lemma 9. Thus since $\mathbb{P}(X_{T_{r}} > 0) \to 1$ by Theorem 1, (14) holds. 

\[\square\]
Now assume that (15) holds. We have from Lemma 9 that \( r^\alpha k(r) \to \infty \) while from (51) \( \liminf_{r \downarrow 0} \frac{A(r)}{r^k(r)} > 0 \). Hence as \( r \downarrow 0 \)

\[ A(r)r^{\alpha - 1} = \frac{A(r)}{r^k(r)}r^\alpha k(r) \to \infty. \]

\[ \square \]
