Abstract

The objective of this work is to prove in a first step the existence and the uniqueness of a solution of the following multivalued deterministic differential equation:

\[
\begin{cases}
  dx(t) + \partial^\ast \varphi (x(t))(dt) \ni dm(t), & t > 0, \\
  x(0) = x_0,
\end{cases}
\]

where \( m : \mathbb{R}_+ \to \mathbb{R}^d \) is a continuous function and \( \partial^\ast \varphi \) is the Fréchet subdifferential of a \textit{semiconvex} function \( \varphi \); the domain of \( \varphi \) can be \textit{non–convex}, but some regularities of the boundary are required.

The continuity of the map \( m \mapsto x : C([0, T]; \mathbb{R}^d) \to C([0, T]; \mathbb{R}^d) \) associating to the input function \( m \) with the solution \( x \) of the above equation, as well as tightness criteria allow to pass from the above deterministic case to the following stochastic variational inequality driven by a multi–dimensional Brownian motion:

\[
\begin{cases}
  X_t + K_t = \xi + \int_0^t F(s, X_s)ds + \int_0^t G(s, X_s)dB_s, & t \geq 0, \\
  dK_t(\omega) \in \partial^\ast \varphi (X_t(\omega))(dt).
\end{cases}
\]

AMS Classification subjects: 60H10, 60J60.

Keywords or phrases: Skorohod Problem; Stochastic Variational Inequalities; Fréchet Subdifferential.
1 Introduction

Given a multi–dimensional Brownian motion \( B = (B_t) \) and a proper semiconvex function \( \varphi \) (for the definition the reader is referred to Definition 11 from the next section) defined over a possibly non–convex domain \( \text{Dom}(\varphi) \) and a random variable \( \xi \) independent of \( B \), which takes its values in the closure of \( \text{Dom}(\varphi) \), we are interested in the following multi–valued stochastic differential equations (also called stochastic variational inequality) driven by the Fréchet subdifferential operator \( \partial^\varphi \):

\[
\begin{cases}
X_t + K_t = \xi + \int_0^t F(s, X_s) \, ds + \int_0^t G(s, X_s) \, dB_s, & t \geq 0, \\
dK_t(\omega) \in \partial^\varphi (X_t(\omega)) (dt).
\end{cases}
\]

(1)

However, in order to study the above system, we shall first solve the following deterministic counterpart of the above equation. Given a continuous function \( m : \mathbb{R}^+ \to \mathbb{R}^d \) and an initial value \( x_0 \in \text{Dom}(\varphi) \) we look for a pair of continuous functions \((x, k) : \mathbb{R}^+ \to \mathbb{R}^2^d\) such that

\[
\begin{cases}
x(t) + k(t) = x_0 + \int_0^t f(s, x(s)) \, ds + m(t), & t \geq 0, \\
dk(t) \in \partial^\varphi (x(t)) (dt).
\end{cases}
\]

(2)

The notation \( dk(t) \in \partial^\varphi (x(t)) (dt) \) means that, for any continuous function \( y : \mathbb{R}^+ \to \mathbb{R}^d \) and any \( 0 \leq s \leq t \), the bounded variation of \( k \) on \([s, t]\) is finite (i.e. \( \int_s^t k \, s - \int_s^t k \, s < +\infty \)) and the following inequality holds:

\[
\int_s^t \langle y(r) - x(r), dk(r) \rangle + \int_s^t \varphi (x(r)) \, dr \leq \int_s^t \varphi (y(r)) \, dr + \int_s^t |y(r) - x(r)|^2 (\rho \, dr + \gamma d \int_s^t k \, s).
\]

With the particular choice of \( f \equiv 0 \) and \( \varphi \) as indicator function of a closed domain \( E \subset \mathbb{R}^d \),

\[
\varphi (x) = I_E (x) := \begin{cases}
0, & \text{if } x \in E, \\
+\infty, & \text{if } x \notin E,
\end{cases}
\]

equation (2) turns turns out to be just the Skorohod problem, i.e, a reflection problem, associated to the data \( x_0, m \) and \( E \). For this reason we will refer to equation (1) as Skorohod equation.

The existence of solutions for both the Skorohod equation (2) and for the stochastic equation (1), has been well studied by different authors for the case, where \( \varphi \) is a convex function. In this case \( \partial^\varphi \) becomes a maximal monotone operator and the domain \( \text{Dom}(\varphi) \) in which the solution is kept is convex. By replacing \( \partial^\varphi \) by a general maximal monotone operator \( A \), E. Cépa [10] generalized the above equation in the finite dimensional case, while A. Răşcanu [26] investigated the infinite dimensional case.

Deterministic variational inequalities, i.e., deterministic equations of type (2), with convex \( \varphi \) and \( m = 0 \) have been well studied and the corresponding results have by now become classical. As concerns the non–convex case, the reader is referred to A. Marino, M. Tosques.
The particular case of a reflection problem, i.e., with \( \varphi = I_E \), was extended to that of moving domains \( E(t) \), \( t \geq 0 \), by considering the following problem (which solution is called sweeping process):

\[
\begin{cases}
  x'(t) + N_{E(t)}(x(t)) \ni f(t, x(t)), & t \geq 0, \\
  x(0) = x_0,
\end{cases}
\]

where \( N_{E(t)}(x(t)) = \partial^- I_{E(t)}(x(t)) \) is the external normal cone to \( E(t) \) in \( x(t) \).

This problem was introduced by J.J. Moreau (see [24]) for the case \( f \equiv 0 \) and convex sets \( E(t) \), \( t \geq 0 \), and it has been intensively studied since then by several authors; see, e.g., C. Castaing [8], M.D.P. Monteiro Marques [23]. For the case of a sweeping process without the assumption of convexity on the sets \( E(t) \), \( t \geq 0 \), we refer to [3], [4], [11] and [13]. The extension to the case \( f \neq 0 \) was considered, e.g., in C. Castaing, M.D.P. Monteiro Marques [9] and J.F. Edmond, and L. Thibault [16] (See also the references therein). Another extension was made in [22] and [28] by considering the quasivariational sweeping process

\[
\begin{cases}
  x'(t) + N_{E(t, x(t))}(x(t)) \ni 0, & t \geq 0, \\
  x(0) = x_0,
\end{cases}
\]

The works mentioned above concern the case with vanishing driving force \( m = 0 \). Let us discuss now the case of equation (2) with singular input \( dm/dt \). The associated reflection problem with singular input \( dm/dt \) has been investigated by A.V. Skorohod in [33] and [34] (for the particular case of \( E = [0, \infty) \)), by H. Tanaka in [35] (for a general convex domain \( E \)), and by P.-L. Lions and A.S. Sznitman in [20] and Y. Saisho in [32] for a non-convex domains. Generalizations from the reflection problem (with \( \partial \varphi = \partial I_E \)) to the case of \( \partial \varphi \) for a general convex function \( \varphi \), and even to the case of a maximal monotone operator \( A \), were discussed by A. Rășcanu in [26], V. Barbu and A. Rășcanu in [2] and by E. Cépa in [10].

Concerning the stochastic equations, we shall mention the papers [20] by P.-L. Lions and A.S. Sznitman and [32] by Y. Saisho, but also [15] by P. Dupuis and H. Ishii for stochastic differential equations with reflecting boundary conditions. On the other hand, A. Rășcanu [26], I. Asiminoaei and A. Rășcanu [1] as well as A. Bensoussan and A. Rășcanu [5] studied stochastic variational inequalities (1) in the convex case.

More recently, A. M. Gassous, A. Rășcanu and E. Rotenstein obtained in [17] existence and uniqueness results for stochastic variational inequalities with oblique subgradients. More precisely, in their equation the direction of reflection at the boundary of the convex domain differs from the normal direction, an effect which is caused by the presence of a multiplicative Lipschitz matrix acting on the subdifferential operator. In the authors’ approach it turned out to be crucial to pass first by a study of the Skorohod problem with generalized reflection.

An interesting approach for both the Skorohod problem and for stochastic variational inequalities (even in the case of a general maximal monotone operator) was provided by A. Rășcanu and E. Rotenstein. In [27] they used the Fitzpatrick function in order to prove by tools from the convex analysis that there exists a one-to-one correspondence between the solutions of multivalued deterministic or stochastic differential systems and the minimum points of some well chosen convex functionals.
The objective of the present work is to generalize both the (non–)convex reflection problem as well as convex variational inequalities to non–convex variational inequalities. Some studies in this direction have been made already by A. M. Gassous, A. Răşcanu and E. Rotenstein in [18]: A non–convex setup for multivalued (deterministic) differential equations driven by oblique subgradients has been established and the uniqueness and the local existence of the solution has been proven.

Our approach here in the present manuscript is heavily based on an a priori discussion of the generalized Skorohod problem ([2]) with \( f \equiv 0 \) and semiconvex \( \varphi \). We’ll give useful a priori estimates and prove the existence and the uniqueness of a solution \((x, k)\) for the generalized Skorohod problem:

\[
\begin{align*}
\left\{ \begin{array}{l}
x(t) + k(t) &= x_0 + m(t), \quad t \geq 0,
\end{array} \right.
\end{align*}
\]

where \( x_0 \in \text{Dom}(\varphi) \), the input \( m \) is a continuous function starting from zero, and \( \partial \varphi \) is the Fréchet subdifferential of a proper, lower semicontinuous and semiconvex function \( \varphi \). Here the set \( \text{Dom}(\varphi) \) is not necessarily convex, but however two assumptions are required:

1. \( \text{Dom}(\varphi) \) satisfies the uniform exterior ball condition (see Definition 1);
2. \( \text{Dom}(\varphi) \) satisfies the \((\gamma, \delta, \sigma)\)–shifted uniform interior ball condition, i.e.

\[
\forall y \in E, \text{ there are some } \lambda_y \in (0, 1] \text{ and } v_y \in \mathbb{R}^d (|v_y| \leq 1) \text{ with } \lambda_y - (|v_y| + \lambda_y)^2 \gamma \geq \sigma \text{ and }
\]

\[
\overline{B}(x + v_y, \lambda_y) \subset E, \quad \text{for all } x \in E \cap \overline{B}(y, \delta).
\]

We observe that this condition is fulfilled if, in particular, the domain \( \text{Dom}(\varphi) \) satisfies the uniform interior drop condition (see Definition 5). It is worth pointing out that the shifted uniform interior ball condition is comparable with assumption (5) of P–L. Lions, A.S. Sznitman [20] (or Condition (B) from [32]) (see the Remarks 21–22).

The application \( m \mapsto x : C([0, T] ; \mathbb{R}^d) \rightarrow C([0, T] ; \mathbb{R}^d) \), which associates to the input function \( m \) the solution \( x \) of (3), will be proven to be continuous. This allows to derive the existence of a solution to the associated stochastic equation with additive noise \( M = (M_t) \):

\[
\begin{align*}
\left\{ \begin{array}{l}
X_t(\omega) + K_t(\omega) &= \xi(\omega) + M_t(\omega), \quad t \geq 0, \quad \omega \in \Omega, \\
dK_t(\omega) &\in \partial \varphi(X_t(\omega)) (dt).
\end{array} \right.
\end{align*}
\]

After having the existence, the uniqueness and properties for the equations (3) and (4), we’ll be able to extend the study to the more general equations (2) and (1), where \( f \) (respectively \( F \)) will be supposed to be continuous and monotone with respect to the second variable and to satisfy the following boundedness assumption:

\[
\int_0^T f^\#(s) \, ds < \infty, \quad \forall T \geq 0, \text{ where } f^\#(t) := \sup \{ |f(t, x)| : x \in \text{Dom}(\varphi) \}.
\]

The article is organized as it follows: The next section is devoted to a recall of such basic notions as those of a as semiconvex set, a semiconvex function or a Fréchet subdifferential.
Some notions, like for instance that of a semiconvex function, are illustrated by an example. In Section 3 we give the definition of the solution to the generalized Skorohod problem (3), we prove the existence and the uniqueness of a solution \((x, k)\) and we give some useful a priori estimations. Moreover, we extend equation (3) to the stochastic case (4). Section 4 is devoted to the proof of the both main results of Section 3. Finally, the Sections 5 and 6 study the extension of the results established in Section 3 to the equations (2) and (1). The Appendix is devoted to important auxiliary results such as applications of Fatou’s Lemma, some complements concerning tightness in \(C(\mathbb{R}_+; \mathbb{R}^d)\) or a very useful forward stochastic inequality, which are used in our approach.

2 Preliminaries

We recall first some definitions and results concerning the notions of normal cone, uniform exterior ball conditions, semiconvex sets, semiconvex functions, Fréchet subdifferential of a function.

Here and everywhere below \(E\) will be a nonempty closed subset of \(\mathbb{R}^d\). Let \(N_E(x)\) be the closed external normal cone of \(E\) at \(x \in \text{Bd}(E)\) i.e.

\[
N_E(x) := \left\{ u \in \mathbb{R}^d : \lim_{\delta \to 0} \frac{d_E(x + \delta u)}{\delta} = |u| \right\},
\]

where \(d_E(z) := \inf \{|z - x| : x \in E\}\) is the distance of a point \(z \in \mathbb{R}^d\) to \(E\).

**Definition 1** Let \(r_0 > 0\). We say that \(E\) satisfies the \(r_0\)-uniform exterior ball condition (we write it \(r_0-\text{UEBC}\) for brevity) if

- \(N_E(x) \neq \{0\}\) for all \(x \in \text{Bd}(E)\),
- For all \(x \in \text{Bd}(E)\) and \(u \in N_E(x)\) such that \(|u| = r_0\) it holds that
  \[
d_E(x + u) = r_0
  \]
  (or equivalent \(B(x + u, r_0) \cap E = \emptyset\), where \(B(x, r)\) denotes the ball from \(\mathbb{R}^d\) of centre \(x\) and radius \(r\)).

We remark that for all \(v \in N_E(x)\) with \(|v| \leq r_0\) we also have \(d_E(x + v) = |v|\).

**Definition 2** Let \(\gamma \geq 0\). A set \(E\) is \(\gamma\)-semiconvex if for all \(x \in \text{Bd}(E)\) there exists \(\hat{x} \in \mathbb{R}^d \setminus \{0\}\) such that

\[
\langle \hat{x}, y - x \rangle \leq \gamma |\hat{x}| |y - x|^2, \quad \forall y \in E.
\]

We have the following equivalence:

**Lemma 3** Let \(r_0 > 0\). The set \(E\) satisfies the \(r_0-\text{UEBC}\) if and only if \(E\) is \(\frac{1}{2r_0}\)-semiconvex.
For an given $z \in \mathbb{R}^d$ we denote by $\Pi_E (z)$ the set of elements $x \in E$ such that $d_E (z) = |z - x|$. Obviously, $\Pi_E (z)$ is non empty since $E$ is non empty and closed. Moreover, under the $r_0$–uniform exterior ball condition, it follows that the set $\Pi_E (z)$ is a singleton for all $z$ such that $d_E (z) < r_0$. In this case $\pi_E (z)$ will denote the unique element of $\Pi_E (z)$ and it is called the projection of $z$ on $E$. We recall the following well–known property of the projection.

**Lemma 4** Let the $r_0 − UEBC$ be satisfied, $\varepsilon \in (0, r_0)$ and $\overline{U}_\varepsilon (E) := \{ y \in \mathbb{R}^d : d_E (y) \leq \varepsilon \}$ denoting the closed $\varepsilon$–neighborhood of $E$.

Then:

- the closed external normal cone of $E$ at $x$ is given by
  \[ N_E (x) = \left\{ \hat{x} : \langle \hat{x}, y - x \rangle \leq \frac{1}{2r_0} |\hat{x}| |y - x|^2, \forall y \in E \right\}; \]

- the projection $\pi_E$ restricted to $\overline{U}_\varepsilon (E)$ is Lipschitz with Lipschitz constant $L_\varepsilon = r_0/(r_0 - \varepsilon)$; and

- the function $d_E^2 (\cdot)$ is of class $C^1$ on $\overline{U}_\varepsilon (E)$ with
  \[ \frac{1}{2} \nabla d_E^2 (z) = z - \pi_E (z) \quad \text{and} \quad z - \pi_E (z) \in N_E (\pi_E (z)), \forall z \in \overline{U}_\varepsilon (E). \]

Let us introduce now the notion of drop of vertex $x$ and running direction $v$.

Let $x, v \in \mathbb{R}^d$, $r > 0$. The set

\[ D_x (v, r) := \text{conv} \{ x, \overline{B} (x + v, r) \} = \{ x + t (u - x) : u \in \overline{B} (x + v, r), t \in [0, 1] \} \]

is called $(|v|, r)$–drop of vertex $x$ and running direction $v$. Remark that if $|v| \leq r$, then $D_x (v, r) = \overline{B} (x + v, r)$.

**Definition 5** The set $E \subset \mathbb{R}^d$ satisfies the uniform interior drop condition if there exist $r_0, h_0 > 0$ such that for all $x \in E$ there exists $v_x \in \mathbb{R}^d$ with $|v_x| \leq h_0$ and

\[ D_x (v_x, r_0) \subset E \]

(we also say that $E$ satisfies the uniform interior $(h_0, r_0)$–drop condition).

**Remark 6** It is easy to see that if there exists $r_0 > 0$ such that $E^c$ satisfies the the $r_0 − UEBC$, then $E$ satisfies the uniform interior $(h_0, r_0)$–drop condition.

Indeed let $x \in \text{Bd} (E^c) = \text{Bd} (E)$ and $u_x \in N_{E^c} (x)$ with $|u_x| = r_0$.

Then

\[ D_x (u_x, r_0/2) \subset D_x (u_x, r_0) = \overline{B} (x + u_x, r_0) \subset E. \]

It is easy to see that, for any $x \in \text{int} (E)$, there exists a direction $v_x \in \mathbb{R}^d$ such that $|v_x| \leq r_0$ and $D_x (v_x, r_0/2) \subset E.$
We state below that the drop condition implies (but is not equivalent with) a weaker condition (for the proof see Proposition 4.35 in [25]).

**Proposition 7** Let the set $E$ be as above with $\text{Int} (E) \neq \emptyset$. If set $E$ satisfies the uniform interior $(h_0, r_0)$-drop condition then $E$ satisfies the shifted uniform interior ball condition, which means that there exist $\gamma \geq 0$ and $\delta, \sigma > 0$, and for every $y \in E$ there exist $\lambda_y \in (0, 1]$ and $v_y \in \mathbb{R}^d$, $|v_y| \leq 1$ such that

\[
\begin{align*}
(i) & \quad \lambda_y - (|v_y| + \lambda_y)^2 \geq \sigma, \\
(ii) & \quad \overline{B}(x + v_y, \lambda_y) \subset E, \quad \forall x \in E \cap \overline{B}(y, \delta)
\end{align*}
\]  

(this condition will be called $(\gamma, \delta, \sigma)$-SUIBC).

**Example 8** Let $E$ be a set for which there exists a function $\phi \in C_b^2(\mathbb{R}^d)$ such that

\[
\begin{align*}
(i) & \quad E = \{ x \in \mathbb{R}^d : \phi (x) \leq 0 \}, \\
(ii) & \quad \text{Int} (E) = \{ x \in \mathbb{R}^d : \phi (x) < 0 \}, \\
(iii) & \quad \text{Bd} (E) = \{ x \in \mathbb{R}^d : \phi (x) = 0 \} \text{ and } |\nabla \phi (x)| = 1, \forall x \in \text{Bd} (E).
\end{align*}
\]

Then the set $E$ satisfies the uniform exterior ball condition and the uniform interior drop condition.

Indeed, using the definition of $E$ we see that, for $x \in \text{Bd} (E)$, the gradient $\nabla \phi (x)$ is a unit normal vector to the boundary, pointing towards the exterior of $E$. Therefore, for any $x \in \text{Bd} (E)$, the normal cone is given by $N_E (x) = \{ c \nabla \phi (x) : c \geq 0 \}$ and $N_{E^c} (x) = \{ -c \nabla \phi (x) : c \geq 0 \}$.

Since $\phi (y) \leq 0 = \phi (x)$, for all $y \in E$, $x \in \text{Bd} (E)$,

\[
\langle \nabla \phi (x), y - x \rangle = \phi (y) - \phi (x) - \int_0^1 \langle \nabla \phi (x + \lambda (y - x)) - \nabla \phi (x), y - x \rangle d\lambda \leq M |y - x|^2,
\]

which means, using Definition 2 and Lemma 3, that $E$ satisfies UEB.

Since $\phi (y) \geq 0 = \phi (x)$, for all $y \in E^c$, $x \in \text{Bd} (E)$,

\[
\langle -\nabla \phi (x), y - x \rangle = -\phi (y) + \int_0^1 \langle \nabla \phi (x + \lambda (y - x)) - \nabla \phi (x), y - x \rangle d\lambda \leq M |y - x|^2,
\]

which yields that $E^c$ satisfies UEB and consequently (see Remark 6) $E$ satisfies the uniform interior drop condition.

If $E$ denotes a closed subset of $\mathbb{R}^d$ let $E_\varepsilon$ be the $\varepsilon$-interior of $E$, i.e.

\[E_\varepsilon := \{ x \in E : d_{E^c} (x) \geq \varepsilon \}.
\]

**Example 9** If $E \subset \mathbb{R}^d$ is a closed convex set such that $\exists r_0 > 0$, such that (the $r_0$-interior of $E$) $E_{r_0} \neq \emptyset$ and $h_0 = \sup_{z \in E} d_{E_{r_0}} (z) < \infty$ (in particular if $E$ is a bounded closed convex set), then $E$ satisfies the uniform interior $(h_0, r_0)$-drop condition.

Moreover for every $0 < \delta \leq \frac{r_0}{2(1+h_0)} \wedge 1$, $E$ satisfies $(\gamma, \delta, \sigma)$-SUIBC with $\lambda_y = \sigma = \delta$.  

7
For the proof, let \( y \in E \), \( \hat{y} \) the projection of \( y \) on the set \( E_{r_0} \) and \( v_y = \frac{1}{1+h_0} (\hat{y} - y) \). Hence \( |\hat{y} - y| \leq h_0 \), \( |v_y| \leq 1 \) and for all \( x \in E \cap B(y, \delta) \)
\[
B(x + v_y, \delta) \subset B(y + v_y, \frac{r_0}{1+h_0}) \subset \text{conv} \left\{ y, B(\hat{y}, r_0) \right\} = D_y(\hat{y} - y, r_0) \subset E.
\]

Let \( \varphi : \mathbb{R}^d \rightarrow (-\infty, +\infty] \) be a function with domain defined by
\[
\text{Dom}(\varphi) := \left\{ v \in \mathbb{R}^d : \varphi(v) < +\infty \right\}.
\]

We say that \( \varphi \) is proper if the domain \( \text{Dom}(\varphi) \neq \emptyset \) and has no isolated points.

We recall now the definition of the Fréchet subdifferential (for this kind of subdifferential operator see, e.g., [21] and the monograph [29], cap. VIII):

**Definition 10** The Fréchet subdifferential \( \partial^- \varphi \) is defined by:

a\textsubscript{1}) \( \partial^- \varphi(x) = \emptyset \), if \( x \notin \text{Dom}(\varphi) \) and

a\textsubscript{2}) for \( x \in \text{Dom}(\varphi) \),
\[
\partial^- \varphi(x) = \left\{ \hat{x} \in \mathbb{R}^d : \liminf_{y \rightarrow x} \frac{\varphi(y) - \varphi(x) - \langle \hat{x}, y - x \rangle}{|y - x|} \geq 0 \right\}.
\]

We set
\[
\text{Dom}(\partial^- \varphi) = \left\{ x \in \mathbb{R}^d : \partial^- \varphi(x) \neq \emptyset \right\},
\]
\[
\partial^- \varphi = \left\{ (x, \hat{x}) : x \in \text{Dom}(\partial^- \varphi), \hat{x} \in \partial^- \varphi(x) \right\}.
\]

In the particular case of the indicator function of the closed set \( E \),
\[
\varphi(x) = I_E(x) := \begin{cases} 0, & \text{if } x \in E, \\ +\infty, & \text{if } x \notin E, \end{cases}
\]
the function \( \varphi \) is lower semicontinuous and the Fréchet subdifferential becomes
\[
\partial^- I_E(x) = \left\{ \hat{x} \in \mathbb{R}^d : \limsup_{y \rightarrow x, y \in E} \frac{\langle \hat{x}, y - x \rangle}{|y - x|} \leq 0 \right\}.
\]

Moreover, in this particular case we deduce that, for any closed subset \( E \) of a Hilbert space,
\[
\partial^- I_E(x) = N_E(x)
\]
(for the proof see Colombo and Goncharov [12]).

**Definition 11** Let \( \rho, \gamma \geq 0 \). The function \( \varphi : \mathbb{R}^d \rightarrow (-\infty, +\infty] \) is said to be \((\rho, \gamma)\)–semiconvex function if

a\textsubscript{1}) \( \text{Dom}(\varphi) \) is \( \gamma \)-semiconvex,

a\textsubscript{2}) \( \text{Dom}(\partial^- \varphi) \neq \emptyset \),

a\textsubscript{3}) For all \( (x, \hat{x}) \in \partial^- \varphi \) and \( y \in \mathbb{R}^d \),
\[
\langle \hat{x}, y - x \rangle + \varphi(x) \leq \varphi(y) + (\rho + \gamma |\hat{x}|) |y - x|^2.
\]
Remark 12 We see that

1. $I_E$ is $(0, \gamma)$–semiconvex iff $E$ is $\gamma$–semiconvex.

2. A convex function is also $(\rho, \gamma)$–semiconvex function, for any $\rho, \gamma \geq 0$.

3. The closed set $E$ is 0–semiconvex if and only if $E$ is convex.

4. If $\varphi : \mathbb{R}^d \to (-\infty, +\infty]$ is a $(\rho, \gamma)$–semiconvex function, then there exists $a \in \mathbb{R}$ such that
   $$\varphi(y) + a|y|^2 + a \geq 0$$
   for all $y \in \mathbb{R}^d$.

Example 13 If the set $E$ satisfy the $r_0$ – UEBC and $g \in C^2 (\mathbb{R}^d)$ (or $g$ is a continuous convex function), then $f : \mathbb{R}^d \to (-\infty, +\infty]$ given by $f(x) := I_E(x) + g(x)$ is a lower semicontinuous semiconvex function. Moreover

$$|f(x) - f(y)| \leq L |x - y|, \forall x, y \in \text{Dom}(f) = E.$$

In order to define the solution for the deterministic problem envisaged by our work it is necessary to introduce the bounded variation function space.

Let $T > 0$, $k : [0, T] \to \mathbb{R}^d$ and $\mathcal{D}$ be the set of the partitions of the interval $[0, T]$. Set

$$S_\Delta(k) = \sum_{i=0}^{n-1} |k(t_{i+1}) - k(t_i)|$$

and

$$\|k\|_{BV([0,T]; \mathbb{R}^d)} := \sup_{\Delta \in \mathcal{D}} S_\Delta(k), \quad \quad (6)$$

where $\Delta : 0 = t_0 < t_1 < \ldots < t_n = T$.

Write

$$BV([0,T]; \mathbb{R}^d) = \{k : [0, T] \to \mathbb{R}^d : \|k\|_{BV([0,T]; \mathbb{R}^d)} < \infty\}.$$

The space $BV([0,T]; \mathbb{R}^d)$ equipped with the norm $\|k\|_{BV([0,T]; \mathbb{R}^d)} := |k(0)| + \|k\|_{BV([0,T]; \mathbb{R}^d)}$ is a Banach space.

Moreover, we have the duality

$$(C([0, T]; \mathbb{R}^d))^* = \{k \in BV([0, T]; \mathbb{R}^d) : k(0) = 0\}$$

given by the Riemann–Stieltjes integral

$$(y, k) \mapsto \int_0^T \langle y(t), dk(t) \rangle.$$

We will say that a function $k \in BV_{loc}(\mathbb{R}_+; \mathbb{R}^d)$ if, for every $T > 0$, $k \in BV([0,T]; \mathbb{R}^d)$. 

3 Generalized Skorohod problem

The aim of this section is to prove the existence and uniqueness result for the following deterministic Cauchy type differential equation:

\[
\begin{aligned}
& dx(t) + \partial^- \varphi(x(t)) (dt) \ni dm(t), \quad t > 0, \\
& x(0) = x_0,
\end{aligned}
\]

where

(i) \( x_0 \in \text{Dom}(\varphi) \),

(ii) \( m \in C(\mathbb{R}_+; \mathbb{R}^d), \ m(0) = 0 \),

and

\( \varphi : \mathbb{R}^d \to (-\infty, +\infty] \) is a proper lower semicontinuous

and \((\rho, \gamma)\)–semiconvex function. (9)

**Definition 14 (Generalized Skorohod problem)** A pair \((x, k)\) of continuous functions \(x, k : \mathbb{R}_+ \to \mathbb{R}^d\), is a solution of equation (7) if

(j) \( x(t) \in \text{Dom}(\varphi), \ \forall t \geq 0 \) and \( \varphi(x(\cdot)) \in L^1_{\text{loc}}(\mathbb{R}_+) \),

(jj) \( k \in BV_{\text{loc}}(\mathbb{R}_+; \mathbb{R}^d), \ k(0) = 0 \),

(jjj) \( x(t) + k(t) = x_0 + m(t), \ \forall t \geq 0 \),

(jv) \( \forall 0 \leq s \leq t, \ \forall y : \mathbb{R}_+ \to \mathbb{R}^d \) continuous:

\[
\int_s^t \langle y(r) - x(r), dk(r) \rangle + \int_s^t \varphi(x(r)) \ dr \leq \int_s^t \varphi(y(r)) \ dr \]

\[
+ \int_s^t |y(r) - x(r)|^2 (pdr + \gamma d\text{up}_r).
\]

In this case the pair \((x, k)\) is said to be the solution of the generalized Skorohod problem \((\partial^- \varphi; x_0, m)\) (denoted by \((x, k) = \text{SP}(\partial^- \varphi; x_0, m)\)).

If \( \varphi = I_E \) then \( \partial^- \varphi = N_E \) and we say that \((x, k)\) is solution of the Skorohod problem \((E; x_0, m)\) and we write \((x, k) = \text{SP}(E; x_0, m)\).

**Remark 15** The notation

\[
dk(t) \in \partial^- \varphi(x(t)) (dt)
\]

means that \(x, k : \mathbb{R}_+ \to \mathbb{R}^d\) are continuous functions satisfying conditions (10–j, jj, jv).

The next result provides an equivalent condition for (10–jv) and will be used later in the proof of the continuity of the mapping \((x_0, m) \mapsto (x, k) = \text{SP}(\partial^- \varphi; x_0, m)\) and for the main existence result in the stochastic case.

**Lemma 16** We suppose that \( \varphi \) satisfies assumption (9) and let \(x, k : \mathbb{R}_+ \to \mathbb{R}^d\) be two continuous functions satisfying (10–j, jj). Then the pair \((x, k)\) satisfies (10–jv) if and only if there exists a
continuous increasing function \( A : \mathbb{R}_+ \to \mathbb{R}_+ \), such that
\[
(jv') \quad \forall \, 0 \leq s \leq t, \forall y : \mathbb{R}_+ \to \mathbb{R}^d \text{ continuous:}
\]
\[
\int_s^t \langle y(r) - x(r), dk(r) \rangle \, dr + \int_s^t \varphi(x(r)) \, dr \leq \int_s^t \varphi(y(r)) \, dr
\]
\[
+ \int_s^t |y(r) - x(r)|^2 \, dA_r .
\]
(11)

**Proof.** We only need to prove that (11) \( \Rightarrow \) (10\( - jv \)).

Denote
\[
Q_r := r + \downarrow k_r + A_r
\]
and let \( \theta, \lambda, \eta \) be measurable functions (given by the Radon–Nikodym’s theorem) such that
\[
dk(r) = \theta(r) \, dQ_r , \quad dr = \lambda(r) \, dQ_r \quad \text{and} \quad dA_r = \eta(r) \, dQ_r.
\]
Clearly\( d\downarrow k_r \) = \( |\theta(r)| \) \( dQ_r \) and \( 0 \leq \lambda(r) \leq 1 \), \( dQ_r \)-a.e., and, from (11) we deduce that, for all \( 0 \leq s \leq t \) and \( z \in \text{Dom}(\varphi) \)
\[
\int_s^t \langle z - x(r), \theta(r) \rangle \, dQ_r + \int_s^t \varphi(x(r)) \lambda(r) \, dQ_r \leq \varphi(z) \int_s^t \lambda(r) \, dQ_r
\]
\[
+ \int_s^t |z - x(r)|^2 \eta(r) \, dQ_r , \quad \text{a.e.}
\]

Now we use an auxiliary result:

**Lemma 17** Let \( a : [0, \infty) \to \mathbb{R} \) be a strictly increasing continuous function and \( f : [0, \infty) \to \mathbb{R} \) be a bounded measurable function.

If
\[
\int_u^v f(r) \, da(r) \geq 0 , \quad \forall \, 0 \leq u \leq v,
\]
then
\[
f(t) \geq 0 , \quad da(t)-\text{a.e.}
\]

**Sketch of the proof:** by making the change of variable \( s = a(r) \) in the Lebesgue–Stieltjes integral and passing to the limit we see that, for all \( \varepsilon > 0 \),
\[
0 \leq \frac{1}{\varepsilon} \int_t^{a^{-1}(a(t) + \varepsilon)} f(r) \, da(r) = \frac{1}{\varepsilon} \int_{a(t)}^{a(t) + \varepsilon} f(a^{-1}(s)) \, ds \xrightarrow[\varepsilon \to 0]{} f(t)
\]

Hence, applying this Lemma, we deduce that, \( \forall z \in \text{Dom}(\varphi) \),
\[
\langle z - x(r), \theta(r) \rangle + \varphi(x(r)) \lambda(r) \leq \varphi(z) \lambda(r) + |z - x(r)|^2 \eta(r) , \quad dr-\text{a.e.}
\]

and from the definition of the Fréchet subdifferential we obtain
\[
\frac{\theta(r)}{\lambda(r)} \in \partial^- \varphi(x(r)) , \quad \forall \, r \in \mathbb{R}_+ \setminus \Gamma,
\]
where $\Gamma = \{ r \geq 0 : \lambda (r) = 0 \}$ with $\int_\Gamma dr = 0$.

Since $\varphi$ is a $(\rho, \gamma)$-semiconvex function, we have for any continuous $y : \mathbb{R}^+ \to \mathbb{R}^d$,

$$\langle y (r) - x (r), \frac{\theta (r)}{\lambda (r)} \rangle + \varphi (x (r)) \leq \varphi (y (r)) + |y (r) - x (r)|^2 \left( \rho + \gamma \frac{\theta (r)}{\lambda (r)} \right),$$

$\forall r \in \mathbb{R}^+ \setminus \Gamma$.

Therefore (with the convention $0 \cdot (0^+) = 0$) for all $r \in \mathbb{R}^+$:

$$\langle y (r) - x (r), \theta (r) \rangle + \varphi (x (r)) \lambda (r) \leq \varphi (y (r)) \lambda (r)
+ |y (r) - x (r)|^2 (\rho \lambda (r) + \gamma |\theta (r)|)$$

(we use also that $\text{Dom}(\varphi)$ is $\gamma$-semiconvex).

Integrating on $[s, t]$ with respect to the measure $dQ_{r}$ we infer that (10–iv) holds. ■

**Lemma 18** If $d k (t) \in \partial^- \varphi (x (t)) (dt)$ and $d \hat{k} (t) \in \partial^- \varphi (\hat{x} (t)) (dt)$, then for all $0 \leq s \leq t$

$$\int_s^t |x (r) - \hat{x} (r)|^2 \left( 2 \rho d r + \gamma d \downarrow k \uparrow r + \gamma d \downarrow \hat{k} \downarrow r \right)
+ \int_s^t \langle x (r) - \hat{x} (r), d k (r) - d \hat{k} (r) \rangle \geq 0.$$ (12)

**Proof.** The conclusion follows from (10–iv) written for $(x, k)$ with $y = \hat{x}$ and for $(\hat{x}, \hat{k})$ with $y = x$. ■

**Notation 19** Let $\|x\|_{[s, t]} := \sup_{r \in [s, t]} |x_r|$ and $\|x\|_{t} := \|x\|_{[0, t]}$.

**Theorem 20 (Uniqueness)** Let assumptions (8) and (9) be satisfied. If $(x, k) = SP (\partial^- \varphi; x_0, m)$ and $(\hat{x}, \hat{k}) = SP (\partial^- \varphi; \hat{x}_0, \hat{m})$ then for all $t \geq 0$:

$$\|x - \hat{x}\|_{t}^2 \leq 2 \left( |x_0 - \hat{x}_0|^2 + \|m - \hat{m}\|_{t}^2 + 2 \|m - \hat{m}\|_{t} \|k - \hat{k}\|_{t} \right)
\cdot \exp (8 \rho t + 4 \gamma \downarrow k \uparrow t + 4 \gamma \downarrow \hat{k} \downarrow t).$$ (13)

In particular the uniqueness of the problem $SP (\partial^- \varphi; x_0, m)$ follows.

**Proof.** We clearly have

$$|x (t) - m (t) - \hat{x} (t) + \hat{m} (t)|^2 = |x_0 - \hat{x}_0|^2
+ 2 \int_0^t \langle m (r) - \hat{m} (r), d k (r) - d \hat{k} (r) \rangle - 2 \int_0^t \langle x (r) - \hat{x} (r), d k (r) - d \hat{k} (r) \rangle.$$

Using (12) it follows that

$$\frac{1}{2} |x (t) - \hat{x} (t)|^2 - |m (t) - \hat{m} (t)|^2 \leq |x (t) - m (t) - \hat{x} (t) + \hat{m} (t)|^2
\leq |x_0 - \hat{x}_0|^2 + \|m - \hat{m}\|_{t} \downarrow k - \hat{k} \uparrow t
+ 2 \int_0^t |x (r) - \hat{x} (r)|^2 \left( 2 \rho d r + \gamma d \downarrow k \uparrow r + \gamma d \downarrow \hat{k} \downarrow r \right),$$
which implies, via Gronwall’s inequality, the desired conclusion.

To derive the uniform boundedness and the continuity of the solution of the generalized Skorohod problem we need to introduce some additional assumptions:

$$|\varphi(x) - \varphi(y)| \leq L + L|x - y|, \forall x, y \in \text{Dom}(\varphi) \quad (14)$$

and

$$\text{Dom}(\varphi) \text{ satisfies the } (\gamma, \delta, \sigma)\text{–shifted uniform interior ball condition} \quad (15)$$

(for the definition of $(\gamma, \delta, \sigma)\text{–SUIBC}$, see definition (5)).

Using Proposition 7 we see that assumption (15) is fulfilled if we impose that

$$\text{Dom}(\varphi) \text{ satisfies the } (h_0, r_0)\text{–drop condition,} \quad (16)$$

condition which can be more easily visualized.

Note that the lower semicontinuity of $\varphi$ and the assumption (14) clearly yield that the $\text{Dom}(\varphi)$ is a closed set, and, from the assumption (15) it can be derived that

$$\text{Int}(\text{Dom}(\varphi)) \neq \emptyset.$$ 

**Remark 21** With respect to assumption (15) we mention that technical conditions (5) appear naturally in order to provide an estimate for the total variation of $k$ (see the forthcoming Lemma 30). On the other hand assumption (5) from P–L. Lions and A.S. Sznitman [20] (or Condition (B) from [32]) has the same role (see [20, Lemma 1.2]). In the particular case $\varphi = I_E$ from paper [20], the representation of the bounded variation process $k$ is essential used, and in our case, in an analogous manner, the subdifferential inequality (10–jv) is used (see also the equivalence between inequality (21–jv) and representation (22)). Hence assumption (15) is required by the transition from the particular case of the indicator function to the case of a general convex l.s.c. function $\varphi$.

**Remark 22** Concerning the drop condition we notice that it is similar with the condition of uniform interior cone condition from [32, Condition (B’)], but we see that the running direction from the drop condition is not ask to be uniformly.

In order to prove some a priori estimates, let us introduce the following notation: for $y \in C\left([0,T];\mathbb{R}^d\right)$ and $\varepsilon > 0$ write

$$\mu_y(\varepsilon) = \varepsilon + m_y(\varepsilon),$$

where $m_y(\varepsilon)$ is the modulus of continuity, given by

$$m_y(\varepsilon) := \sup \left\{ |y(t) - y(s)| : |t - s| \leq \varepsilon, \ t, s \in [0,T] \right\}.$$

The function $\mu_y : [0,T] \to [0,\mu_y(T)]$ is a strictly increasing continuous function and therefore the inverse function $\mu_y^{-1} : [0,\mu_y(T)] \to [0,T]$ is well defined and is also a strictly increasing continuous function. Using this inverse function let $C$ be a positive constant and this

$$\Delta_m := 1/\mu_m^{-1}(\delta^2 \exp[-C \left(1 + T + \|m\|_T\right)]),$$

$$C_{T,m} := \exp[C \left(1 + T + \|m\|_T + \Delta_m\right)]. \quad (17)$$
Remark 23 It is easy to prove that, for any compact subset $M \subset C \left([0, T]; \mathbb{R}^d\right)$,

$$\Delta M := \sup_{m \in M} \Delta_m < \infty \quad \text{and} \quad C_{T,M} := \sup_{m \in M} C_{T,m} < \infty. \tag{18}$$

The main results of this section are the following two theorems whose proofs will be given in the next section:

Theorem 24 Let assumptions (8), (9), (14) and (15) be satisfied. Then there exists a constant $C$, depending only on the constants from the assumptions, such that if $(x, k) = SP \left(\partial^- \varphi; x_0, m\right)$ then

(a) $\|k\|_{BV([0, T]; \mathbb{R}^d)} = \frac{1}{\|k\|_{T}} \leq C_{T,m}$,

(b) $\|x\|_{T} \leq |x_0| + C_{T,m}$,

(c) $|x(t) - x(s)| + \frac{1}{\|k\|_{T}} - \frac{1}{\|k\|_{s}} \leq C_{T,m} \cdot \sqrt{\|m\|_{T}}$, \quad $\forall 0 \leq s \leq t \leq T$.

If moreover $\hat{m} \in C \left([0, T]; \mathbb{R}^d\right)$, $\hat{x}_0 \in \text{Dom}(\varphi)$ and $(\hat{x}, \hat{k}) = SP(\partial^- \varphi; \hat{x}_0, \hat{m})$, then

$$\|x - \hat{x}\|_{T} + \|k - \hat{k}\|_{T} \leq C_{T} \cdot \left[\|x_0 - \hat{x}_0\| + \sqrt{\|m - \hat{m}\|_{T}}\right], \tag{20}$$

where $C_T$ depends continuously on $C_{T,m}$ and $C_{T,\hat{m}}$.

Theorem 25 Let assumptions (8), (9), (14) and (15) be satisfied. Then the generalized Skorohod problem

$$\begin{cases} x(t) + k(t) = x_0 + m(t), & t \geq 0, \\
 dk(t) \in \partial^- \varphi(x(t)) (dt) \end{cases}$$

has a unique solution $(x, k)$, in the sense of Definition 14 (and we write $(x, k) = SP \left(\partial^- \varphi; x_0, m\right)$).

We can now derive the following continuity result of the mapping $(x_0, m) \mapsto (x, k) = SP \left(\partial^- \varphi; x_0, m\right)$.

Corollary 26 Let assumptions (8), (9), (14) and (15) be satisfied. If $x_0, x_0 \in \text{Dom}(\varphi), m, m \in C \left(\mathbb{R}_+; \mathbb{R}^d\right), m_n(0) = 0$ and

(i) $(x_n, k_n) = SP \left(\partial^- \varphi; x_0, m\right)$,

(ii) $x_0 \rightarrow x_0$,

(iii) $m_n \rightarrow m$ in $C \left([0, T]; \mathbb{R}^d\right)$, \quad $\forall T \geq 0$,

then

$$\sup_{n \in \mathbb{N}} \frac{1}{\|k_n\|_{T}} < \infty, \quad \forall T \geq 0,$$

and there exist $x, k \in C \left(\mathbb{R}_+; \mathbb{R}^d\right)$ such that, for any $T \geq 0$,

(a) $\|x_n - x\|_{T} + \|k_n - k\|_{T} \rightarrow 0$,

(b) $(x, k) = SP \left(\partial^- \varphi; x_0, m\right)$. 

**Proof.** Let us fix arbitrary $T > 0$. The set $M = \{m, m_n : n \in \mathbb{N}^*\}$ is a compact subset of $C\left([0, T] ; \mathbb{R}^d\right)$. If $C_{T,m}$ is the constant defined by (17), then, using (18), it follows that

$$C_{T,M} := \sup_{x \in M} C_{T,x} < \infty.$$ 

Also

$$\mu_M(\varepsilon) := \sup_{x \in M} \mu_x(\varepsilon) \searrow 0, \text{ as } \varepsilon \searrow 0.$$ 

Let $a > 0$ be such that $|x_{0n}| \leq a$. By the estimates established in Theorem 24 we obtain: for all $n, l \in \mathbb{N}^*$ and for all $s, t \in [0, T], s \leq t$,

$$\|x_n\|_T + k_n \uparrow_T \leq a + C_{T,M},$$

$$|x_n(t) - x_n(s)| + k_n \uparrow t - k_n \downarrow s \leq C_{T,M} \cdot \sqrt{\mu_M(t-s)}$$

and

$$\|x_n - x_l\|_T + \|k_n - k_l\|_T \leq C_{T,M} \cdot \left[ \|x_{0n} - x_{0l}\| + \sqrt{\|m_n - m_l\|_T} \right].$$

Therefore there exist $x, k, A \in C\left([0, T] ; \mathbb{R}^d\right)$ such that

$$x_n \to x, \quad k_n \to k, \quad \text{in } C\left([0, T] ; \mathbb{R}^d\right), \text{ as } n \to \infty,$$

and, by Arzelà–Ascoli’s Theorem, on a subsequence denoted also with $k_n \uparrow$,  

$$k_n \uparrow \to A, \text{ in } C\left([0, T] ; \mathbb{R}^d\right), \text{ as } n \to \infty,$$

where $A$ is an increasing function starting from zero.

Clearly, the pair $(x, k)$ satisfies (10–j, jj, jjj) and (11), which means, using Lemma 16, that $(x, k) = SP (\partial^- \varphi; x_0, m)$. 

Before giving the proof of the main results, Theorems 24 and 25, let us examine the particular case of the indicator function of the closed set $E$ (which yields the classical Skorohod problem).

If $E$ satisfies the $r_0 – UEBC$, then, by Lemmas 3 and 4 and Definition 11, the set $E$ is $\frac{1}{2r_0}$–semiconvex and the indicator function $I_E (x)$ is a $(0, \frac{1}{2r_0})$–semiconvex function. Hence assumptions (9) and (14) are satisfied.

We write the definition of the solution of the Skorohod problem in the case of the indicator function.

**Definition 27 (Skorohod problem)** Let $E \subset \mathbb{R}^d$ be a set satisfying the $r_0 – UEBC$. A pair $(x, k)$ is a solution of the Skorohod problem if $x, k : \mathbb{R}_+ \to \mathbb{R}^d$ are continuous functions and

\begin{align*}
& (j) \quad x(t) \in E, \\
& (jj) \quad k \in BV_{\text{loc}}(\mathbb{R}_+ ; \mathbb{R}^d), \quad k(0) = 0, \\
& (jjj) \quad x(t) + k(t) = x_0 + m(t), \\
& (jv) \quad \forall 0 \leq s \leq t \leq T, \forall y \in C(\mathbb{R}_+ ; E)
\end{align*}

\begin{align*}
\int_s^t \langle y(r) - x(r), dk(r) \rangle \leq \frac{1}{2r_0} \int_s^t |y(r) - x(r)|^2 \ d \uparrow k \downarrow r.
\end{align*}

(21)
The following theorem is a consequence of the main existence Theorem 25.

**Theorem 28** Let \( x_0 \in E \) and \( m : \mathbb{R}_+ \to \mathbb{R}^d \) be a continuous function such that \( m(0) = 0 \). If \( E \) satisfies the \( r_0 - U E B C \), for some \( r_0 > 0 \), and the shifted uniform interior ball condition, then there exists a unique solution of the Skorohod problem, in the sense of Definition 27.

Moreover, each one of the following conditions are equivalent with \((21-\text{jv})\):

\[
\begin{align*}
(j\nu') & \quad \exists \beta > 0 \text{ such that } \forall y \in \mathbb{R}_+ \to E \text{ continuous}, \\
& \quad \int_s^t |y(r) - x(r)| \, dk(r) \leq \beta \int_s^t |y(r) - x(r)|^2 \, d\|k_r\| \, k_r. \tag{23}
\end{align*}
\]

Proof. In order to obtain the uniqueness, we shall use Theorem 20 and next inequality: if \((x, k) = \mathcal{S}P(E; x_0, m)\) and \((\hat{x}, \hat{k}) = \mathcal{S}P(E; \tilde{x}_0, \tilde{m})\), then from \((21)\) we get (also see Lemma 18)

\[
\langle x(t) - \hat{x}(t), dk(t) - d\hat{k}(t) \rangle + \frac{1}{2r_0} |x(t) - \hat{x}(t)|^2 (d\kappa_r + d\hat{\kappa}_r) \geq 0.
\]

The existence is due to Theorem 25 (but, for a direct proof of the existence, with condition \((21-\text{jv})\) replaced by \((22)\), we refer the reader to [20]).

Proof of \((22) \implies (21-\text{jv}):\) using Lemma 3 we see

\[
\begin{align*}
\int_s^t \langle y(r) - x(r), dk(r) \rangle & = \int_s^t \langle y(r) - x(r), n_{x(r)} \rangle \kappa_r \\
& = \int_s^t \langle y(r) - x(r), n_{x(r)} \rangle \kappa_r \\
& = \frac{1}{2r_0} \int_s^t |n_{x(r)}| |y(r) - x(r)|^2 \kappa_r \\
& \leq \frac{1}{2r_0} \int_s^t |y(r) - x(r)|^2 d\kappa_r.
\end{align*}
\]

Clearly \((21-\text{jv}) \implies (23)\).

Proof of \((23) \implies (22):\) let \([s, t]\) be an interval such that \(x(r) \in \text{Int}(E)\) for all \(r \in [s, t]\). Then there exists \(\delta = \delta_{s,t} > 0\) such that

\[
\inf_{r \in [s, t]} d_{\text{Bd}(E)}(x(r)) \geq \delta.
\]

Let \(\lambda \in [0, \delta]\) and \(\alpha \in C([0, T]; \mathbb{R}^d)\) such that \(\|\alpha\|_T \leq 1\). Setting \(y(r) = x(r) + \lambda \alpha(r)\) in \((23)\) we obtain

\[
\int_s^t \langle \alpha(r), dk(r) \rangle \leq \beta \lambda \int_s^t d\kappa_r.
\]
Hence, passing to the limit, for \( \lambda \to 0 \), and taking \( \sup_{\| \alpha \| \leq 1} \), we deduce the implication:

\[
x (r) \in \text{Int} (E), \forall r \in [s, t] \implies \xi k_{t_r}^{\downarrow} - \xi k_{s_r}^{\downarrow} = 0. \quad (24)
\]

Let \( \ell (r) \) be a measurable function such that \( |\ell (r)| = 1, d \xi k_{t_r}^{\downarrow} \)-a.e. and

\[
k (t) = \int_{0}^{t} \ell (r) d \xi k_{t_r}^{\downarrow}.
\]

Since (23) holds for all \( 0 \leq s \leq t \),

\[
\langle \ell (r), y (r) - x (r) \rangle \leq \beta |y (r) - x (r)|^2, \quad d \xi k_{t_r}^{\downarrow} \)-a.e.,
\]

for any \( y \in C ([0, T] ; E) \). Therefore, from Lemma 4, we infer that

\[
\ell (r) \in N_E (x (r)), \quad d \xi k_{t_r}^{\downarrow} \)-a.e. \quad (25)
\]

We have thus proved inequality (22), since we have (24) and (25).

\section{Generalized Skorohod problem: proofs}

In order to prove Theorem 25 let us first prove some auxiliary results.

Let \((x, k) = SP (\partial^{-} \varphi; x_0, m) \) and \( y \in C (\mathbb{R}_+ ; E) \), where \( E = \text{Dom} (\varphi) \). From (14), for all \( 0 \leq s \leq t \),

\[
\int_{s}^{t} \langle y (r) - x (r), dk (r) \rangle \leq L (t - s) + L \int_{s}^{t} |y (r) - x (r)| \, dr
\]

\[
+ \int_{s}^{t} |y (r) - x (r)|^2 (\rho \, dr + \gamma d \xi k_{t_r}^{\downarrow}). \quad (26)
\]

Suppose that \( x (r) \in \text{Int} (\text{Dom} (\varphi)) \) for all \( r \in [s, t] \), and let

\[
0 < b \leq \inf_{r \in [s, t]} d_{\text{Bd}(E)} (x (r)).
\]

Write \( y (r) = x (r) + \lambda \alpha (r) \) with \( \alpha \in C (\mathbb{R}_+ ; \mathbb{R}^d) \), \( \| \alpha \|_{[s, t]} \leq 1 \) and \( 0 < \lambda < 1 \). Hence the above inequality becomes, for \( \lambda = \left[ (1 + \gamma) (1 + b)^2 \right]^{-1} \)

\[
\lambda b \int_{s}^{t} \langle \alpha (r), dk (r) \rangle \leq (L + Lb) (t - s) + \lambda^2 b^2 |\rho (t - s) + \gamma (\xi k_{t_r}^{\downarrow} - \xi k_{s_r}^{\downarrow})|
\]

\[
\leq (L + Lb + \lambda^2 b^2 \rho) (t - s) + \frac{\lambda b}{1 + b} (\xi k_{t_r}^{\downarrow} - \xi k_{s_r}^{\downarrow}).
\]

Taking the supremum over all \( \alpha \) such that \( \| \alpha \|_{[s, t]} \leq 1 \) we see that

\[
\frac{\lambda b^2}{1 + b} (\xi k_{t_r}^{\downarrow} - \xi k_{s_r}^{\downarrow}) \leq (L + Lb + \lambda^2 b^2 \rho) (t - s).
\]

Consequently, the following result is proved:
Lemma 29 Let \( \varphi \) such that assumption (14) is satisfied and \( (x, k) = \mathcal{S}\mathcal{P} (\partial^- \varphi; x_0, m) \). If \( x (r) \in \text{Int (Dom} (\varphi)) \), for all \( r \in [s, t] \), then there exists a positive constant \( C = C (L, \rho, \gamma, b) \) such that

\[
\downarrow k\uparrow_t - \downarrow k\uparrow_s \leq C (t - s)
\]

where

\[
0 < b \leq \inf_{r \in [s, t]} d_{\text{Bd}(E)} (x (r)) .
\]

More general we have

Lemma 30 Let \( \varphi \) be a \((\rho, \gamma)\)–semiconvex function and \( (x, k) = \mathcal{S}\mathcal{P} (\partial^- \varphi; x_0, m) \). Assume that \( \varphi \) satisfies assumption (14) and set \( \text{Dom} (\varphi) \) satisfies assumption (15). If \( 0 \leq s \leq t \) and

\[
\sup_{r \in [s, t]} |x (r) - x (s)| \leq \delta,
\]

then there exists \( \sigma > 0 \) such that

\[
\downarrow k\uparrow_t - \downarrow k\uparrow_s \leq \frac{1}{\sigma} |k (t) - k (s)| + \frac{3L + 4\rho}{\sigma} (t - s) .
\]

(27)

Proof. Let us fix arbitrarily \( \alpha \in C ([R^+; \mathbb{R}^d]) \) such that \( \|\alpha\|_{[s, t]} \leq 1 \). From assumptions (14–15), if

\[
y (r) := x (r) + v_{x(s)} + \lambda_{x(s)} \alpha (r), \ r \in [s, t],
\]

then \( y (r) \in E \). Moreover

\[
|y (r) - x (r)| \leq |v_{x(s)}| + \lambda_{x(s)} \leq 2
\]

and

\[
|\varphi (y (r)) - \varphi (x (r))| \leq 3L.
\]

From (26) we deduce that

\[
\lambda_{x(s)} \int_s^t (\alpha (r), dk (r)) \leq - \int_s^t \langle v_{x(s)}, dk (r) \rangle + (3L + 4\rho) (t - s) + \gamma \int_s^t (|v_{x(s)}| + \lambda_{x(s)})^2 d \downarrow k\uparrow_r .
\]

Taking the supremum over all \( \alpha \) such that \( \|\alpha\|_{[s, t]} \leq 1 \) we see, using also (5), that

\[
\sigma (\downarrow k\uparrow_t - \downarrow k\uparrow_s) \leq |k (t) - k (s)| + (3L + 4\rho) (t - s)
\]

and the Lemma follows.

Proof of Theorem 24. We denote by \( C, C', C'' \) generic constants independent of \( x_0, \hat{x}_0, m, \hat{m} \) and \( T \), but possibly depending on constants \( L, \delta, \sigma, \rho, \gamma \) provided by the assumptions.

Step 1. Some estimates of the modulus of continuity of the function \( x \).

Let \( 0 \leq s \leq t \leq T \).

Since

\[
|x (t) - x (s) - m (t) + m (s)| = |k (t) - k (s)| \leq \downarrow k\uparrow_t - \downarrow k\uparrow_s ,
\]

18
it follows that
\[ |x(t) - x(s)| \leq |m(t) - m(s)| + \frac{1}{2} k^r_{t} - k^s_{t} . \]

We clearly have
\[ |x(t) - x(s) - m(t) + m(s)|^2 = 2 \int_s^t (m(r) - m(s), dk(r)) \]
\[ + 2 \int_s^t \langle x(r) - x(r), dk(r) \rangle . \]

From (10–14) written for \( y(r) \equiv x(s) \) and (14) we have
\[ \int_s^t \langle x(s) - x(r), dk(r) \rangle \leq L (t - s) + \int_s^t |x(s) - x(r)| \, dr \]
\[ + \int_s^t |x(s) - x(r)|^2 (\rho dr + \gamma dk^r_{s}) . \]

Thus, using also the inequality \( \frac{1}{2} |\alpha|^2 \leq |\alpha - \beta|^2 + |\beta|^2 \), we get
\[ \frac{1}{2} |x(t) - x(s)|^2 \leq |m(t) - m(s)|^2 + 2 m_m (t - s) (\frac{1}{2} k^r_{t} - k^s_{s}) + C (t - s) \]
\[ + C \int_s^t |x(r) - x(s)|^2 (dr + d k^r_{s}) , \]
and, by Gronwall’s inequality,
\[ |x(t) - x(s)|^2 \leq \left[ m_m^2 (t - s) + m_m (t - s) (\frac{1}{2} k^r_{t} - k^s_{s}) + (t - s) \right] \]
\[ \cdot \exp \left[ C (1 + t - s + k^r_{t} - k^s_{s}) \right] , \] (28)
for all \( 0 \leq s \leq t \leq T \).

Step 2. Estimates of the differences \( |x(t) - x(s)| \) and \( \frac{1}{2} k^r_{t} - k^s_{s} \) under the assumption \( |x(t) - x(s)| \leq \delta \).

Let \( 0 \leq s \leq r \leq t \leq T \) such that \( |x(t) - x(s)| \leq \delta \). From (27) we have
\[ \frac{1}{2} k^r_{t} - k^s_{s} \leq C |k(t) - k(s)| + C (t - s) \]
\[ = C |x(t) - x(s) - m(t) + m(s)| + C (t - s) \]
\[ \leq C |x(t) - x(s)| + C m_m (t - s) + C (t - s) \leq C \delta + C m_m (t - s) . \]

Using the estimate (28), it clearly follows that
\[ |x(t) - x(s)|^2 \leq m_m (t - s) \exp \left[ C (1 + T + \|m\|_T) \right] , \text{ for all } 0 \leq s \leq t \leq T , \]

since \( (t - s) + m_m (t - s) = m_m (t - s) \leq T + 2 \|m\|_T \).

Hence if \( 0 \leq s \leq t \leq T \) and \( |x(t) - x(s)| \leq \delta \) then
\[ |x(t) - x(s)| + \frac{1}{2} k^r_{t} - k^s_{s} \leq \sqrt{m_m (t - s)} \cdot \exp \left[ C (1 + T + \|m\|_T) \right] . \] (29)

Step 3. Adapted time partition and local estimates.
Let the sequence given by (the definition is suggested by [20])

\[
t_0 = T_0 = 0, \\
T_1 = \inf \{ t \in [t_0, T] : d_{\text{Bd}(E)}(x(t)) \leq \delta/4 \}, \\
t_i = \inf \{ t \in [T_i, T] : |x(t) - x(T_i)| > \delta/2 \}, \\
T_i = \inf \{ t \in [t_i, T] : d_{\text{Bd}(E)}(x(t)) \leq \delta/4 \}, \\
T_{i+1} = \inf \{ t \in [T_i, T] : |x(t) - x(T_i)| > \delta/2 \}
\]

Clearly

\[
0 = T_0 = t_0 \leq T_1 < t_1 \leq T_2 < \cdots < t_i \leq T_{i+1} < t_{i+1} \leq \cdots \leq T.
\]

Let \( t_i \leq r \leq T_{i+1} \). Then \( x(r) \in \text{Int}(E) \) and \( d_{\text{Bd}(E)}(x(r)) \geq \delta/4 \). By Lemma 29 we get

\[
|k(t) - k(s)| \leq \frac{\delta}{4} k_s^t - \frac{\delta}{4} k_t^s \leq C (t - s) \text{ for } t_i \leq s \leq t \leq T_{i+1}.
\]

Also for \( t_i \leq s \leq t \leq T_{i+1} \):

\[
|x(t) - x(s)| \leq |k(t) - k(s)| + |m(t) - m(s)| \leq C (t - s) + |m(t) - m(s)| \\
\leq C \mu_m(t - s)
\]

and then

\[
|x(t) - x(s)| + \frac{\delta}{4} k_s^t - \frac{\delta}{4} k_t^s \leq C \mu_m(t - s).
\]

On each of the intervals \([T_i, t_i]\), we have

\[
|x(t) - x(s)| \leq \delta, \text{ for all } T_i \leq s \leq t \leq t_i.
\]

and consequently, for all \( T_i \leq s \leq t \leq t_{i+1} \), inequality (29) holds.

If \( T_i \leq s \leq t \leq t_{i+1} \) then

\[
|x(t) - x(s)| + \frac{\delta}{4} k_s^t - \frac{\delta}{4} k_t^s \\
\leq |x(t) - x(t_i)| + \frac{\delta}{4} k_s^{t_i} - \frac{\delta}{4} k_t^{t_i} + |x(t_i) - x(s)| + \frac{\delta}{4} k_s^{t_i} - \frac{\delta}{4} k_t^{s} \\
\leq C \mu_m(t - t_i) + \sqrt{\mu_m(t_i - s)} \cdot \exp \left[ C (1 + T + \|m\|_T) \right] \\
\leq \sqrt{\mu_m(t - s)} \cdot \exp \left[ C' (1 + T + \|m\|_T) \right].
\]

Consequently for all \( i \in \mathbb{N} \) and \( T_i \leq s \leq t \leq T_{i+1} \), inequality (29) holds.

Step 4. Getting inequalities (19).

Since \( \mu_m^{-1} : [0, \mu_m(T)] \to [0, T] \) is well defined and is a strictly increasing continuous function, from

\[
\frac{\delta}{4} \leq |x(t_i) - x(T_i)| \leq \sqrt{\mu_m(t_i - T_i)} \cdot \exp \left[ C (1 + T + \|m\|_T) \right] \\
\leq \sqrt{\mu_m(T_{i+1} - T_i)} \cdot \exp \left[ C (1 + T + \|m\|_T) \right],
\]

20
we deduce that

\[ T_{i+1} - T_i \geq \mu_m^{-1} \left( \frac{\delta^2}{4} \exp \left[ -2C \left( 1 + T + \|m\|_T \right) \right] \right) \]

\[ \geq \mu_m^{-1} \left( \delta^2 \exp \left[ -2C' \left( 1 + T + \|m\|_T \right) \right] \right) > 0. \]

Hence the bounded increasing sequence \((T_i)_{i \geq 0}\) has a finite numbers of terms, therefore there exists \(j \in \mathbb{N}^\ast\) such that \(T = T_j\). Then

\[ T = T_j = \sum_{i=1}^{j} (T_i - T_{i-1}) \geq j\Delta_m^{-1}, \]

where \(\Delta_m := 1/\mu_m^{-1} \left( \delta^2 \exp \left[ -C' \left( 1 + T + \|m\|_T \right) \right] \right) \) (see definition (17)).

Let \(0 \leq s \leq t \leq T\). We have

\[ \downarrow k_s^\downarrow - \downarrow k_s^\downarrow = \sum_{i=1}^{j} \left( \downarrow k_{(t \wedge T_i) \vee s}^\downarrow - \downarrow k_{(t \wedge T_{i-1}) \vee s}^\downarrow \right) \]

\[ \leq \sum_{i=1}^{j} \sqrt{\mu_m \left( (t \wedge T_i) \vee s - (t \wedge T_{i-1}) \vee s \right)} \cdot \exp \left[ C \left( 1 + T + \|m\|_T \right) \right] \]

\[ \leq j \sqrt{\mu_m (t - s)} \cdot \exp \left[ C \left( 1 + T + \|m\|_T \right) \right] \]

\[ \leq T \Delta_m \sqrt{\mu_m (t - s)} \cdot \exp \left[ C \left( 1 + T + \|m\|_T \right) \right] \]

and consequently

\[ \downarrow k_T^\downarrow \leq T \Delta_m \sqrt{\mu_m (T)} \cdot \exp \left[ C \left( 1 + T + \|m\|_T \right) \right] \leq \exp \left[ C' \left( 1 + T + \|m\|_T + \Delta_m \right) \right] \]

and

\[ |x(t)| = |x_0 + m(t) - k(t)| \leq |x_0| + \|m\|_t + \downarrow k_t^\downarrow \leq |x_0| + \|m\|_T + \downarrow k_T^\downarrow. \]

Hence there exists a positive constant \(C = C(L, \delta, \sigma, \rho, \gamma)\) such that, under notations (17),

\[ \downarrow k_T^\downarrow \leq C_{T,m}, \quad \text{and} \quad \|x\|_T \leq |x_0| + C_{T,m}, \]

which is part of conclusion (19).

In order to end the proof of (19) it is sufficient to remark that, for any \(0 \leq s \leq t \leq T\),

\[ |x(t) - x(s)|^2 \leq \left[ \mathbf{m}_m^2 (t - s) + \mathbf{m}_m (t - s) C_{T,m} + (t - s) \right] \cdot \exp \left[ C \left( 1 + C_{T,m} \right) \right] \]

\[ \leq C_{T,m} \mathbf{m}_m (t - s). \]

Step 5. Getting inequality (20).

Since \(\downarrow k_T^\downarrow + \downarrow k_T^\downarrow \leq C_{T,m} + C_{T,m}\), from inequality (13) we have

\[ \|x - \hat{x}\|^2 \leq 2 \left[ |x_0 - \hat{x}_0|^2 + \|m - \hat{m}\|^2_T + 2 \|m - \hat{m}\|_T \|k - \hat{k}\|_T \right] \cdot \exp \left[ 4\gamma (2t + \downarrow k_T^\downarrow + \downarrow k_T^\downarrow) \right] \]

\[ \leq C_T \left[ |x_0 - \hat{x}_0|^2 + \|m - \hat{m}\|_T \right], \]
and the conclusion follows since \( k - \hat{k} = x_0 - \hat{x}_0 + m - \hat{m} - (x - \hat{x}) \).

**Proof of the Theorem 25.** Uniqueness was proved in Theorem 20. To prove existence, let \( m_n \in C^1 (\mathbb{R}^+; \mathbb{R}^d) \) with \( m_n (0) = 0 \) be such that \( \| m_n - m \|_T \to 0 \) for all \( T \geq 0 \). Since \( m_n \in C^1 (\mathbb{R}^+; \mathbb{R}^d) \), we deduce, using the results from the papers [14] or [31], that there exists a unique solution \((x_n, k_n)\) of the \( \mathcal{SP} (\partial^- \varphi; x_0, m_n) \), and by Corollary 26 we see that there exist \( x, k \in C (\mathbb{R}^+; \mathbb{R}^d) \) such that for all \( T \geq 0 \)

\[
\| x_n - x \|_T + \| k_n - k \|_T \to 0, \quad \text{as} \quad n \to \infty,
\]

and

\[
(x, k) = \mathcal{SP} (\partial^- \varphi; x_0, m),
\]

which completes the proof.

### 5 Generalized Skorohod equations

Consider the next (non–convex) variational inequality with singular input (which will be called generalized Skorohod differential equation):

\[
\begin{cases}
  x(t) + k(t) = x_0 + \int_0^t f(s, x(s)) \, ds + m(t), \quad t \geq 0, \\
  dk(t) \in \partial^- \varphi(x(t)) (dt)
\end{cases}
\]

(for the notation \( dk(t) \in \partial^- \varphi(x(t)) (dt) \) we recall Remark 15).

We introduce the following supplementary assumptions:

\[
f(\cdot, x) : \mathbb{R}^+ \to \mathbb{R}^d \text{ is measurable, } \forall x \in \mathbb{R}^d,
\]

and there exists \( \mu \in L^1_{\text{loc}} (\mathbb{R}^+), \) such that a.e. \( t \geq 0 \):

\[
(i) \quad x \mapsto f(t, x) : \mathbb{R}^d \to \mathbb{R}^d \text{ is continuous},
\]

\[
(ii) \quad \langle x - y, f(t, x) - f(t, y) \rangle \leq \mu(t) |x - y|^2, \quad \forall x, y \in \mathbb{R}^d,
\]

\[
(iii) \quad \int_0^T f^\# (s) \, ds < \infty, \quad \forall T \geq 0,
\]

where

\[
f^\# (t) := \sup \left\{ |f(t, x)| : x \in \text{Dom}(\varphi) \right\}.
\]

**Proposition 31 (Generalized Skorohod Equation)** Let \( \varphi : \mathbb{R}^d \to (-\infty, \infty] \) and \( f : \mathbb{R}^+ \times \mathbb{R}^d \to \mathbb{R}^d \) be such that assumptions (8), (9), (14), (15) and (31), (32) are satisfied.

Then the generalized Skorohod equation (30) has a unique solution.

**Proof.** Let \((x, k)\) and \((\hat{x}, \hat{k})\) be two solutions. Then

\[
|x(t) - \hat{x}(t)|^2 + 2 \int_0^t \langle x(r) - \hat{x}(r), \, dk(r) - d\hat{k}(r) \rangle
\]

\[
= 2 \int_0^t \langle x(r) - \hat{x}(r), f(r, x(r)) - f(r, \hat{x}(r)) \rangle \, dr \leq 2 \int_0^t \mu^+(r) |x(r) - \hat{x}(r)|^2 \, dr,
\]

22
and using Lemma 18 it follows that
\[ |x(t) - \hat{x}(t)|^2 \leq 2 \int_0^t |x(r) - \hat{x}(r)|^2 dA_r, \]
where
\[ A_t = 2 \rho t + \gamma \downarrow k \downarrow t + \gamma \uparrow k \uparrow t + \int_0^t \mu^+(r) \, dr. \]

Applying a Gronwall’s type inequality, we see that \( x = \hat{x} \).

Concerning the existence, we shall obtain the solution \((x, k)\) as the limit in \( C([0, T] ; \mathbb{R}^d) \times C([0, T] ; \mathbb{R}^d) \) of the sequence \((x_n, k_n)_{n \in \mathbb{N}^*}\) defined by an approximate Skorohod equation
\[
\begin{cases}
  x_n(t) = x_0, & \text{for } t < 0, \\
  x_n(t) + k_n(t) = x_0 + \int_0^t f(s, x_n(s - 1/n)) \, ds + m(t), & \text{for } t \geq 0,
\end{cases}
\]
(34)

For any \( i \in \mathbb{N} \), for \( t \in \left[ \frac{i}{n}, \frac{i+1}{n} \right] \), we can write
\[ x_n(t) + [k_n(t) - k_n(i/n)] = x_n(i/n) + \int_{i/n}^t f(s, x_n(s - 1/n)) \, ds + m(t) - m(i/n), \]
therefore by iteration over the intervals \( \left[ \frac{i}{n}, \frac{i+1}{n} \right] \) there exists (via Theorem 25) a unique pair \((x_n, k_n) = \mathcal{SP}(\partial^- \varphi; x_0, m_n)\), with
\[ m_n(t) = \int_0^t f(s, x_n(s - 1/n)) \, ds + m(t). \]

Let \( T > 0 \). If \( \mathcal{M} \) denotes the set
\[ \mathcal{M} := \{m_n : n \in \mathbb{N}^*\}, \]
then \( \mathcal{M} \) is a relatively compact subset of \( C([0, T] ; \mathbb{R}^d) \) since it is a bounded and equicontinuous subset of \( C([0, T] ; \mathbb{R}^d) \).

Indeed
\[ \|m_n\|_T \leq \int_0^T f^\#(s) \, ds + \|m\|_T \]
and, for \( s < t \),
\[ |m_n(t) - m_n(s)| \leq \int_s^t f^\#(r) \, dr + |m(t) - m(s)|. \]

Then by Theorem 24 and Remark 23,
\[ \|x_n\|_T + \|^\downarrow k_n\|^T \leq |x_0| + C_{T, \mathcal{M}} \]
and for all \( 0 \leq s \leq t \):
\[ |x_n(t) - x_n(s)| + \|^\downarrow k_n\|_t - \|^\downarrow k_n\|_s \leq C_{T, \mathcal{M}} \sqrt{\mu_{\mathcal{M}}(t-s)}. \]
where \( \mu_M(\varepsilon) := \varepsilon + \sup_{m \in M} m_n \).

Hence, by Arzelà–Ascoli’s theorem, the set \( \{ x_n : n \in \mathbb{N}^* \} \) is a relatively compact subset of \( C([0, T] ; \mathbb{R}^d) \).

Let \( x \in C([0, T] ; \mathbb{R}^d) \) be such that, along a sequence still denoted by \( \{ x_n : n \in \mathbb{N}^* \} \),

\[
\| x_n - x \|_T \to 0, \quad \text{as } n \to \infty.
\]

Then, uniformly with respect to \( t \in [0, T] \),

\[
m_n(t) \to \int_0^t f(s, x(s)) \, ds + m(t), \quad \text{as } n \to \infty,
\]

and

\[
k_n(t) \to k(t) = x_0 + \int_0^t f(s, x(s)) \, ds + m(t) - x(t), \quad \text{as } n \to \infty.
\]

Using Corollary 26 we infer that

\[
(x, k) = SP \left( \partial^- \varphi; x_0, \int_0^t f(s, x(s)) \, ds + m \right)
\]

i.e. \((x, k)\) is a solution of problem (30). The uniqueness of the solution of implies that the whole sequence \((x_n, k_n)\) is convergent to that solution \((x, k)\). The proof is completed now. \(\blacksquare\)

If in the above Proposition we take \( \varphi = I_E \) we get, via Theorem 28,

**Corollary 32 (Skorohod equation)** Let \( x_0 \in E \) and \( m : \mathbb{R}_+ \to \mathbb{R}^d \) be a continuous function such that \( m(0) = 0 \). If \( f \) satisfies assumption (31)–(32) and \( E \) satisfies the \( r_0 - U \) EBC (for some \( r_0 > 0 \)) and the shifted uniform interior ball condition, then there exists a unique pair \((x, k)\) such that:

\[
\begin{align*}
(x, k) \in C(\mathbb{R}^+; E), & \quad k(0) = 0, \\
& k \in BV_{loc}(\mathbb{R}^+; \mathbb{R}^d), \\
x(t) + k(t) = x_0 + \int_0^t f(s, x(s)) \, ds + m(t), & \quad (j) \\
\| k \|_{L^\infty} = \int_0^t \int_{x(s) \in Bd(E)} k \, dB, & \quad (jv) \\
k(t) = \int_0^t n(x(s)) \, dB, & \quad (v)
\end{align*}
\]

where \( n \in N_E(x(s)) \) and \( |n(x(s))| = 1 \), \( d \| k \|_{L^\infty} \) a.e.

### 6 Non–Convex stochastic variational inequalities

In the last section of the paper we will study the following multivalued stochastic differential equation (also called stochastic variational inequality) considered on a non–convex domain:

\[
\begin{align*}
X_t + K_t &= \xi + \int_0^t F(s, X_s) \, ds + \int_0^t G(s, X_s) \, dB_s, \quad t \geq 0, \\
dK_t(\omega) &\in \partial^- \varphi(X_t(\omega)) \, (dt),
\end{align*}
\]

where \( \varphi \) is \((\rho, \gamma)\)-semiconvex function and \( \{ B_t : t \geq 0 \} \) is an \( \mathbb{R}^k \)–valued Brownian motion with respect to a stochastic basis (which is supposed to be complete and right–continuous) \((\Omega, \mathcal{F}, \mathbb{P}, \{ \mathcal{F}_t \}_{t \geq 0})\).

First we derive directly from Theorem 25 the existence result in the additive noise case.
Corollary 33 Let \( (\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t)_{t \geq 0} \) be given. If
\[
\xi \in L^0(\Omega, \mathcal{F}_0, \mathbb{P}; \overline{\text{Dom}}(\varphi))
\]
and \( M \) is a progressively measurable and continuous stochastic processes (p.m.c.s.p. for short) with \( M_0 = 0 \), then there exists a unique pair \((X, K)\) of p.m.c.s.p., solution of the problem
\[
\begin{align*}
X_t(\omega) + K_t(\omega) &= \xi(\omega) + M_t(\omega), \quad t \geq 0, \ \omega \in \Omega, \\
dK_t(\omega) &\in \partial^{-}\varphi(X_t(\omega))(dt)
\end{align*}
\]
(in this case we shall write \((X(\omega), K(\omega)) = \mathcal{SP}(\partial^{-}\varphi; \xi(\omega), M(\omega)), \ \mathbb{P} \text{ – a.s.}).

Proof. Let \( \omega \) be arbitrary but fixed. By Theorem 25, the Skorohod problem
\[
(X(\omega), K(\omega)) = \mathcal{SP}(\partial^{-}\varphi; \xi(\omega), M(\omega))
\]
has a unique solution
\[
(X(\omega), K(\omega)) \in C([0, T]; \mathbb{R}^d) \times C([0, T]; \mathbb{R}^d).
\]
Since \((\omega, t) \mapsto M_t(\omega)\) is progressively measurable and the mapping
\[
(\xi, M) \mapsto X : \overline{\text{Dom}}(\varphi) \times C([0, t]; \mathbb{R}^d) \to C([0, t]; \mathbb{R}^d)
\]
is continuous for each \(0 \leq t \leq T\), the stochastic process \( X \) is progressively measurable. Hence the conclusion follows.

The next assumptions will be needed throughout this section:

(A1) (Carathéodory conditions) The functions \( F(\cdot, \cdot, \cdot) : \Omega \times \mathbb{R}^d \to \mathbb{R}^d \) and \( G(\cdot, \cdot, \cdot) : \Omega \times \mathbb{R}^d \to \mathbb{R}^{d \times k}\) are \((\mathcal{P}, \mathbb{R}^d)\)-Carathéodory functions, i.e.
\[
\begin{align*}
F(\cdot, \cdot, x) \text{ and } G(\cdot, \cdot, x) &\text{ are p.m.s.p., } \forall x \in \mathbb{R}^d, \\
F(\omega, t, \cdot) \text{ and } G(\omega, t, \cdot) &\text{ are continuous function } d\mathbb{P} \otimes dt-\text{a.e.}
\end{align*}
\]

(A2) (Boundedness conditions) For all \( T \geq 0\):
\[
\int_0^T F^\#(s) \, ds < \infty \quad \text{and} \quad \int_0^T |G^\#(s)|^2 \, ds < \infty, \ \mathbb{P}-\text{a.s.,}
\]
where
\[
F^\#(t) := \sup \left\{ |F(t, x)| : x \in \overline{\text{Dom}}(\varphi) \right\},
\]
\[
G^\#(t) := \sup \left\{ |G(t, x)| : x \in \overline{\text{Dom}}(\varphi) \right\}
\]

(A3) (Monotonicity and Lipschitz conditions) There exist \( \mu \in L^1_{\text{loc}}(\mathbb{R}^+) \) and \( \ell \in L^2_{\text{loc}}(\mathbb{R}^+) \) with \( \ell \geq 0 \), such that \( d\mathbb{P} \otimes dt\)-a.e.
\[
\begin{align*}
(i) \quad &|x - y, F(t, x) - F(t, y)| \leq \mu(t) |x - y|^2, \quad \forall x, y \in \mathbb{R}^d, \\
(ii) \quad &|G(t, x) - G(t, y)| \leq \ell(t) |x - y|, \quad \forall x, y \in \mathbb{R}^d.
\end{align*}
\]
We define now the notions of strong and weak solutions for the stochastic Skorohod equation (36).

**Definition 34** Let \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t)_{t \geq 0}\) be given. A pair \((X, K) : \Omega \times \mathbb{R}_+ \to \mathbb{R}^d \times \mathbb{R}^d\) of continuous \(\mathcal{F}_t\)-p.m.c.s.p. is a strong solution of the stochastic Skorohod equation (36) if \(\mathbb{P}\)-a.s.,

\[
\begin{align*}
  (j) & \quad X_t \in \text{Dom}(\varphi), \forall t \geq 0, \varphi(X_t) \in L^1_{\text{loc}}(\mathbb{R}_+), \\
  (jj) & \quad K_t \in BV_{\text{loc}}(\mathbb{R}_+; \mathbb{R}^d), \quad K_0 = 0, \\
  (jjj) & \quad X_t + K_t = \xi + \int_0^t F(s, X_s) \, ds + \int_0^t G(s, X_s) \, dB_s, \forall t \geq 0, \\
  (jv) & \quad \forall 0 \leq s \leq t, \forall y : \mathbb{R}_+ \to \mathbb{R}^d \text{ continuous } \\
  & \quad \int_s^t \langle y(r) - X_r, dK_r \rangle + \int_s^t \varphi(X_r) \, dr \leq \int_s^t \varphi(y(r)) \, dr \\
  & \quad + \int_s^t |y(r) - X_r|^2 (\rho dr + \gamma d\mathbb{H}^dK_r^\dag),
\end{align*}
\]

which means that

\[
(X(\omega), K(\omega)) = \mathcal{SP}(\partial^{-}\varphi; \xi(\omega), M(\omega)) \text{, } \mathbb{P} - \text{a.s.},
\]

where

\[
M_t = \int_0^t F(s, X_s) \, ds + \int_0^t G(s, X_s) \, dB_s.
\]

**Definition 35** Let \(F(\omega, t, x) := f(t, x), G(\omega, t, x) := g(t, x)\) and \(\xi(\omega) := x_0\) (be independent of \(\omega\)). If there exists a stochastic basis \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t)_{t \geq 0}\) and a \(\mathbb{R}^k\)-valued \(\mathcal{F}_t\)-Brownian motion \(\{B_t : t \geq 0\}\) and a pair \((X, K) : \Omega \times \mathbb{R}_+ \to \mathbb{R}^d \times \mathbb{R}^d\) of p.m.c.s.p. such that

\[
(X(\omega), K(\omega)) = \mathcal{SP}(\partial^{-}\varphi; x_0, M(\omega)), \quad \mathbb{P} - \text{a.s.},
\]

where

\[
M_t = \int_0^t f(s, X_s) \, ds + \int_0^t g(s, X_s) \, dB_s,
\]

then the collection \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t, X_t, K_t)_{t \geq 0}\) it is called a weak solution of the stochastic Skorohod equation (36).

Since the stochastic process \(K\) is uniquely determined from \((X, B)\) through equation (40–jjj), we can also say that \(X\) is a strong solution (and respectively \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t, X_t)_{t \geq 0}\) is a weak solution).

We first give a uniqueness result for strong solutions.

**Proposition 36** (Pathwise uniqueness) Let \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t)_{t \geq 0}\) be given and assumptions (8), (9) and (14) be satisfied. The functions \(F\) and \(G\) are such that assumptions \((A_1\text{-}A_3)\) are satisfied. Then the stochastic Skorohod equation (36) has at most one strong solution.
Proof. Let \((X, K)\) and \((\hat{X}, \hat{K})\) be two solutions corresponding to \(\xi\) and respectively \(\hat{\xi}\). Since
\[
dK_t \in \partial^{-} \varphi (X_t) (dt) \quad \text{and} \quad d\hat{K}_t \in \partial^{-} \varphi (\hat{X}_t) (dt),
\]
by Lemma 18, for \(p \geq 1\) and \(\lambda > 0\)
\[
\begin{align*}
&\langle X_t - \hat{X}_t, (F(t, X_t) dt - dK_t) - (F(t, \hat{X}_t) dt - d\hat{K}_t) \rangle \\
&+ \left( \frac{1}{2} m_p + 9p\lambda \right) |G(t, X_t) - G(t, \hat{X}_t)|^2 dt \leq |X_t - \hat{X}_t|^2 dV_t,
\end{align*}
\]
where
\[
V_t = \int_0^t [\mu(s) ds + \left( \frac{1}{2} m_p + 9p\lambda \right) \ell(s) ds + 2pds + \gamma d\frac{1}{2} K_\ell s + \gamma d\frac{1}{2} \hat{K}_\ell s].
\]
Therefore, by Corollary 50 (from the Appendix), we get
\[
\mathbb{E} \left[ 1 \wedge \|e^{-V}(X - \hat{X})\|_{\mathcal{T}}^p \right] \leq C_{p, \lambda} \mathbb{E} \left[ 1 \wedge |\xi - \hat{\xi}|^p \right],
\]
and the uniqueness follows. 

Remark also that in the case of additive noise (i.e. \(G\) does not depend upon \(X\)) we have existence of a strong solution.

Lemma 37 Let \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t)_{t \geq 0}\) be given and assumptions (8), (9), (14) and (15) be satisfied. The function \(F\) is such that assumptions \((A_1 - A_3)\) are satisfied.

If
\[
\xi \in L^0 (\Omega, \mathcal{F}_0, \mathbb{P}; \overline{\text{Dom} (\varphi)})
\]
and \(M\) is a p.m.c.s.p. with \(M_0 = 0\), then there exists a unique pair \((X, K)\) of p.m.c.s.p., solution of the problem
\[
(X. (\omega) , K. (\omega)) = \mathcal{S} \mathcal{P} (\partial^{-} \varphi ; \xi. (\omega) , M. (\omega)) , \quad \mathbb{P} - a.s.,
\]
i.e.
\[
\begin{align*}
&X_t (\omega) + K_t (\omega) = \xi (\omega) + \int_0^t F (\omega, s, X_s (\omega)) ds + M_t (\omega) , \quad t \geq 0, \\
&dK_t (\omega) \in \partial^{-} \varphi (X_t (\omega)) (dt),
\end{align*}
\]
\(\mathbb{P}-a.s.

Proof. Applying Corollary 33 to the approximating problem
\[
\begin{align*}
&X^n_t (\omega) + K^n_t (\omega) = \xi (\omega) + \int_0^t F (\omega, s, X^n_{s-1/n} (\omega)) ds + M_t (\omega) , \quad t \geq 0, \\
&dK^n_t (\omega) \in \partial^{-} \varphi (X^n_t (\omega)) (dt),
\end{align*}
\]
we conclude that there exists a unique solution \((X^n, K^n)\) of p.m.c.s.p. The solution \((X, K)\) is obtained as the limit of the sequence \((X^n, K^n)\), exactly as in the proof of Proposition 31. 

In order to study the general stochastic Skorohod equation (36) we shall consider only the case when \(F, G\) and \(\xi\) are independent of \(\omega\) and, to highlight this, the coefficients will be denoted by \(f\) and \(g\) respectively.
Let us consider equation

\[
\begin{cases}
X_t + K_t = x_0 + \int_0^t f(s, X_s) \, ds + \int_0^t g(s, X_s) \, dB_s, & t \geq 0, \\
& dK_t(\omega) \in \partial^- \varphi(X_t(\omega)) \,(dt),
\end{cases}
\]  

(41)

where \( f : \mathbb{R}_+ \times \mathbb{R}^d \to \mathbb{R}^d \) and \( g : \mathbb{R}_+ \times \mathbb{R}^d \to \mathbb{R}^{d \times k} \).

We recall the definition of \( f^\#, g^\# \) given as in (33).

**Theorem 38** Let assumptions (8), (9), (14) and (15) be satisfied. The functions \( f \) and \( g \) are supposed to be \((\mathcal{B}_1, \mathbb{R}^d)\)-Carathéodory functions satisfying moreover the boundedness conditions

\[
\int_0^T \left[ |f^\#(s)|^2 + |g^\#(s)|^4 \right] \, ds < \infty, \quad \forall T \geq 0.
\]

If \( x_0 \in \overline{\text{Dom} (\varphi)} \) then equation (41) has a weak solution \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, X_t, K_t, B_t)_{t \geq 0}\).

**Remark 39** Usually, when \( G \) is Lipschitz, a fixed point argument is used (based on Banach contraction theorem). But, in our case this argument doesn’t work even for the drift part \( F \equiv 0 \), as it can be see from inequality (20), we have different order of the estimates in the left and in the right side of the inequality.

**Proof.** Step 1. Approximating sequence.

Let \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t^B, B_t)_{t \geq 0}\) be a stochastic basis. Applying Lemma 37, we deduce that there exists a unique pair \((X^n, K^n) : \Omega \times \mathbb{R}_+ \to \mathbb{R}^d \times \mathbb{R}^d\) of \( \mathcal{F}_t^B \)-p.m.c.s.p. such that

\[
\begin{cases}
X^n_t + K^n_t = x_0 + \int_0^t f(s, X^n_{s-1/n}) \, ds + \int_0^t g(s, X^n_{s-1/n}) \, dB_s, & t \geq 0, \\
& dK^n_t(\omega) \in \partial^- \varphi(X^n_t(\omega)) \,(dt).
\end{cases}
\]  

(42)

Denote

\[ M^n_t := \int_0^t f\left(s, X^n_{s-1/n}\right) \, ds + \int_0^t g\left(s, X^n_{s-1/n}\right) \, dB_s. \]

Since

\[
\mathbb{E} \left[ \sup_{0 \leq \theta \leq \varepsilon} \left| M^n_{t+\theta} - M^n_t \right|^4 \right] \leq C \left[ \left( \int_t^{t+\varepsilon} f^\#(s) \, ds \right)^4 + \left( \int_t^{t+\varepsilon} g^\#(s) \, ds \right)^2 \right] \]

\[
\leq \varepsilon C \left[ \sup_{t \in [0, T]} \left( \int_t^{t+\varepsilon} \left| f^\#(s) \right|^2 \, ds \right)^2 + \sup_{t \in [0, T]} \int_t^{t+\varepsilon} \left| g^\#(s) \right|^4 \, ds \right]
\]

using Proposition 45, we deduce that the family of laws of \( \{M^n : n \geq 1\} \) is tight on \( C \left( \mathbb{R}_+ ; \mathbb{R}^d \right) \).

Therefore by Theorem 44 for all \( T \geq 0 \)

\[ \lim_{N \to \infty} \sup_{n \geq 1} \mathbb{P} \left( \|M^n\|_T \geq N \right) = 0, \]
and, for all $a > 0$ and $T > 0$, 
\[
\lim_{\epsilon \searrow 0} \left[ \sup_{n \geq 1} \mathbb{P} \{ m_{M^n}(\epsilon) \geq a \} \right] = 0. \tag{43}
\]

Recalling the definition 
\[
\mu_{M^n} = \epsilon + m_{M^n}(\epsilon),
\]
where $m$ is the modulus of continuity, we see that we can replace in $43$ $m_{M^n}$ by $\mu_{M^n}$.

Step 2 Tightness.

Let $T \geq 0$ be arbitrary. We now show that the family of laws of the random variables $U^n = (X^n, K^n, K^n\uparrow, B^n)$ is tight on $C \left( [0, T]; \mathbb{R}^{2d+1} \right)$.

From (19–c) we deduce that 
\[
m_{U^n}(\epsilon) \leq G(M^n) \sqrt{\mu_{M^n}(\epsilon)}, \text{ a.s.,}
\]
where $G : C \left( [0, T]; \mathbb{R}^d \right) \to \mathbb{R}_+$ and 
\[
G(x) := C_{T,x} = \exp \left[ C \left( 1 + T + \| x \|_T + B_x \right) \right], \quad B_x := 1/\mu_x^{-1} \left( \delta^2 e^{-C(1+T+\|x\|_T)} \right).
\]

From (18) we see that $G$ is bounded on compact subset of $C \left( [0, T]; \mathbb{R}^d \right)$ and therefore by Proposition 46, $\{U^n; n \in \mathbb{N}^*\}$ is tight on $C \left( [0, T]; \mathbb{R}^d \right)$.

Using the Prohorov theorem we see that there exists a subsequence (still denoted with $n$) such that 
\[
(X^n, K^n, K^n\uparrow, B) \to (X, K, V, B) \quad \text{in law, as } n \to \infty
\]
on $C \left( [0, T]; \mathbb{R}^{2d+1+k} \right)$ and applying the Skorohod theorem, we can choose a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and some random quadruples $(\bar{X}^n, \bar{K}^n, \bar{V}^n, \bar{B}^n)$, $(\bar{X}, \bar{K}, \bar{V}, \bar{B})$ defined on $(\Omega, \mathcal{F}, \mathbb{P})$ such that 
\[
\mathcal{L}(\bar{X}^n, \bar{K}^n, \bar{V}^n, \bar{B}^n) = \mathcal{L}(X^n, K^n, K^n\uparrow, B^n) \quad \mathcal{L}(\bar{X}, \bar{K}, \bar{V}, \bar{B}) = \mathcal{L}(X, K, V, B)
\]
and 
\[
(\bar{X}^n, \bar{K}^n, \bar{V}^n, \bar{B}^n) \xrightarrow{\mathbb{P}-a.s.} (\bar{X}, \bar{K}, \bar{V}, \bar{B}), \text{ as } n \to \infty, \text{ in } C([0, T]; \mathbb{R}^{2d+1+k}).
\]

From Proposition 48 we deduce that $(\bar{B}^n, \{\mathcal{F}_t^{\bar{X}^n, \bar{K}^n, \bar{V}^n, \bar{B}^n}\}), n \geq 1$, and $(\bar{B}, \{\mathcal{F}_t^{\bar{X}, \bar{K}, \bar{V}, \bar{B}}\})$ are Brownian motions.

Step 3 Passing to the limit.

Since we also have $(X^n, K^n, K^n\uparrow, B) \to (\bar{X}, \bar{K}, \bar{V}, \bar{B})$, in law, then by Corollary 42 we deduce that for all $0 \leq s \leq t$, $\mathbb{P}$–a.s.
\[
\bar{X}_0 = x_0, \quad \bar{K}_0 = 0, \quad \bar{X}_t \in \text{Dom}(\varphi), \quad \uparrow K_{\uparrow t} - \uparrow K_{\uparrow s} \leq \bar{V}_t - \bar{V}_s \quad \text{and} \quad 0 = \bar{V}_0 \leq \bar{V}_s \leq \bar{V}_t \tag{44}
\]
Moreover, since for all \(0 \leq s < t, n \in \mathbb{N}^*\)
\[
\int_s^t \varphi (X^n_r) \, dr \leq \int_s^t \varphi (y (r)) \, dr - \int_s^t \langle g (r) - X^n_r, dK^n_r \rangle + \int_s^t \left| \langle g (r) - X^n_r \rangle \right|^2 (\rho dr + \gamma d\mathbb{K}^n), \text{ a.s.}
\]
then by Corollary 43 we infer that
\[
\int_s^t \varphi (\bar{X}_r) \, dr \leq \int_s^t \varphi (y (r)) \, dr - \int_s^t \langle g (r) - \bar{X}_r, d\bar{K}_r \rangle + \int_s^t \left| \langle g (r) - \bar{X}_r \rangle \right|^2 (\rho dr + \gamma d\bar{V}_r).
\] (45)

Hence, based on (44) and (48) and Lemma 16 we have
\[d\bar{K}_r \in \partial^- \varphi (\bar{X}_r) (dr).\]

Let
\[S_t (Y, B) := x_0 + \int_0^t f (s, Y_s) \, ds + \int_0^t g (s, Y_s) \, dB_s, \quad t \geq 0.\]

By Proposition 47 it follows
\[
\mathcal{L}(\bar{X}^n, \bar{K}^n, \bar{V}^n, \bar{B}^n, S_t(\bar{X}^n, \bar{B}^n)) = \mathcal{L}(X^n, K^n, \mathbb{K}^n, B^n, S_t(X^n, B^n))
\]
Since for every \(t \geq 0\),
\[X^n_t + K^n_t - S_t(X^n, B^n) = 0, \text{ a.s.},\]
then by Corollary 42 we have
\[
\bar{X}^n_t + \bar{K}^n_t - S_t(\bar{X}, \bar{B}) = 0, \text{ a.s.},
\]
and consequently, letting \(n \to \infty\),
\[\bar{X}_t + \bar{K}_t - S_t(\bar{X}, \bar{B}) = 0, \text{ a.s.}\]

Hence we obtain that, \(\mathbb{P}\)-a.s.,
\[\bar{X}_t + \bar{K}_t = x_0 + \int_0^t f (s, \bar{X}_s) \, ds + \int_0^t g (s, \bar{X}_s) \, dB_s, \quad \forall t \in [0, T],\]
and consequently \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, \bar{X}_t, \bar{K}_t, B_t)_{t \geq 0}\) is a weak solution.

Since the stochastic process \(K\) is uniquely determined by \((X, B)\) via equation (41), then a weak solution for the stochastic differential equation is a sextuplet \((\Omega, \mathcal{F}, \mathbb{P}, \{\mathcal{F}_t\}_{t \geq 0}, X, B)\). We know that weak existence and pathwise uniqueness implies strong existence (see Theorem 3.55 in [25] or Theorem 1.1 in [19]). Hence we deduce from Theorem 38 and Proposition 36:

**Theorem 40** Let assumptions (8), (9), (14) and (15) be satisfied. The functions \(f\) and \(g\) are supposed to be \((\mathcal{B}_1, \mathbb{R}^d)\)-Carathéodory functions satisfying moreover assumption (A3) and boundedness conditions
\[\int_0^T \left[ |f^\#(s)|^2 + |g^\#(s)|^4 \right] \, ds < \infty, \quad \forall T \geq 0.\]
If \(x_0 \in \text{Dom}(\varphi)\) then equation (41) has a unique strong solution \((X_t, K_t)_{t \geq 0}\).
7 Appendix

7.1 Applications of Fatou’s Lemma

Now we present a generalization of the Fatou’s Lemma. The proof can be found in the book of E. Pardoux and A. Rașcanu [25] (Proposition 1.22).

**Proposition 41** Let \((X, \rho)\) be a separable metric space. Let \(\varphi : X \to (-\infty, \infty)\) be a lower semicontinuous function. If \(X\) and \(X_n\) are \(X\)-valued random variable, for \(n \in \mathbb{N}^*\), such that

\[(i) \quad X_n \overset{law}{\to} X, \text{ as } n \to \infty, \]

and there exists a continuous function \(\alpha : X \to \mathbb{R}\) such that

\[(ii) \quad \alpha(x) \leq \varphi(x), \quad \forall x \in X, \]

\[(iii) \quad \{\alpha(X_n) : n \in \mathbb{N}^*\} \text{ is a uniformly integrable family,} \]

then the expectations \(\mathbb{E}\varphi(X)\) and \(\mathbb{E}\varphi(X_n)\) exist for all \(n \in \mathbb{N}\), and

\[-\infty < \mathbb{E}\varphi(X) \leq \liminf_{n \to +\infty} \mathbb{E}\varphi(X_n).\]

For \(0 \leq s < t \leq T\), we denote by \(\downarrow X_{s,t}^\dagger\) (similar to (6)) the total variation of \(X\) on \([s,t]\), that is

\[\downarrow X_{s,t}^\dagger(\omega) = \sup \left\{ \sum_{i=0}^{n-1} |X_{t_{i+1}}(\omega) - X_{t_i}(\omega)| : n \in \mathbb{N}^*, s = t_0 < t_1 < \cdots < t_n = t \right\}\]

We also use \(\downarrow X_T^\dagger := \downarrow X_{[0,T]}^\dagger\).

Applying successively Proposition 41 for

\[\varphi(x) = d_F(x(t)),\]

\[\varphi(x, y) = \left( \sum_{i=0}^{N-1} |x(t_{i+1}) - x(t_i)| - g(y) \right)^+,\]

where \(s = t_0 < t_1 < \ldots < t_N = t\) is an arbitrary partition of \([s,t]\),

and respectively

\[\varphi(x) = (x(s) - x(t))^+,\]

we get the next result:

**Corollary 42** Let \(0 \leq s \leq t \leq T\). If \(g : C([0,T]; \mathbb{R}^d) \to \mathbb{R}_+\) is a continuous function and \(X, V, X^n, V^n, n \in \mathbb{N}^*,\) are random variables with values in \(C([0,T]; \mathbb{R}^d)\), such that

\[(X^n, V^n) \overset{law}{\to} (X, V), \text{ as } n \to \infty,\]

then the following implications hold true:
(a) If $X^n_t \in F$ a.s., then $X_t \in F$, a.s., whenever $F$ is closed;

(b) If $\uparrow X^n_{t\mid [s,t]} \leq g(V^n)$ a.s., then $\uparrow X^n_{t\mid [s,t]} \leq g(V)$, a.s.;

(c) If $d = 1$ and $X^n_s \leq X^n_t$ a.s., then $X_s \leq X_t$, a.s.

Now let us consider the partition

$$\Delta_N : s = r_0 < r_1 < \ldots < r_N = t, \ r_{i+1} - r_i = \frac{t - s}{N}$$

and the function $g : C \left( \left[0, T\right] ; \mathbb{R}^d \right) \to [0, 1]$, defined by

$$g(x, k, v) := \left( \sum_{i=0}^{N-1} |k(r_{i+1}) - k(r_i)| - v(t) + v(s) \right)^+ \land 1$$

$$+ \left[ \int_s^t \varphi (x(r)) \, dr - \sum_{i=0}^{N-1} \langle x(r_i), k(r_{i+1}) - k(r_i) \rangle - m_k(1/N) (v(t) - v(s)) \right]^+ \land 1.$$

Applying again the generalization of the Fatou’s Lemma (Proposition 41), it can be proved:

**Corollary 43** Let $(X, K, V)$, $(X^n, K^n, V^n)$, $n \in \mathbb{N}$, be $C \left( \left[0, T\right] ; \mathbb{R}^d \right) \times C \left( \left[0, T\right] ; \mathbb{R} \right)$-valued random variables, such that

$$(X^n, K^n, V^n) \xrightarrow{\text{law}} \left( X, K, V \right)$$

and for all $0 \leq s < t$, and $n \in \mathbb{N}^*$,

$$\uparrow K^n_{t\mid t} - \uparrow K^n_{s\mid s} \leq V^n_t - V^n_s \text{ a.s.}.$$

If $\varphi : \mathbb{R}^d \to (-\infty, +\infty)$ is a lower semicontinuous function and

$$\int_s^t \varphi (X^n_r) \, dr \leq \int_s^t \langle X^n_r, dK^n_r \rangle, \text{a.s. for all } n \in \mathbb{N}^*,$$

then

$$\uparrow K^n_{t\mid t} - \uparrow K^n_{s\mid s} \leq V_t - V_s, \text{a.s.}$$

and

$$\int_s^t \varphi (X_r) \, dr \leq \int_s^t \langle X_r, dK_r \rangle, \text{a.s.}$$

### 7.2 Complements on tightness

If $\{X^n_t : t \geq 0\}$, $n \in \mathbb{N}^*$, is a family of continuous stochastic processes then the following result is a consequence of the Arzelà–Ascoli theorem (see, e.g., Theorem 7.3 in [6]).

We recall the notations:

$$\|X^n\|_T := \sup \{|X^n_t| : t \in [0, T]\},$$

$$m_{X^n} (\varepsilon; [0, T]) := \sup \{|X^n_t - X^n_s| : t, s \in [0, T], |t - s| \leq \varepsilon\}.$$
Theorem 44 The family \( \{X^n : n \in \mathbb{N}^* \} \) is tight in \( C(\mathbb{R}_+; \mathbb{R}^d) \) if and only if, for every \( T \geq 0 \),

\[
(j) \lim_{N \to \infty} \sup_{n \geq 1} P^{(n)}( |X^n_0| \geq N) = 0,
\]

\[
(jj) \lim_{\varepsilon \downarrow 0} \sup_{n \geq 1} P^{(n)}( \mathbf{m}_{X^n}( \varepsilon; [0, T]) \geq a) = 0, \quad \forall a > 0.
\]

Moreover, tightness yields that for all \( T > 0 \)

\[
\lim_{N \to \infty} \sup_{n \geq 1} P^{(n)}( \|X^n\|_T \geq N) = 0.
\]

Without using the above theorem, it can be proved the following criterion for tightness which is well adapted to our needs. The proof can be found in E. Pardoux and A. Răşcanu [25] (Proposition 1.53) and we will give the sketch of the proof.

Proposition 45 Let \( \{X^n_t : t \geq 0\}, n \in \mathbb{N}^* \), be a family of \( \mathbb{R}^d \)-valued continuous stochastic processes defined on probability space \((\Omega, \mathcal{F}, P)\). Suppose that for every \( T \geq 0 \), there exist \( \alpha > 0 \) and \( b \in C(\mathbb{R}_+) \) with \( b(0) = 0 \), such that

\[
(j) \lim_{N \to \infty} \sup_{n \in \mathbb{N}^*} P( |X^n_0| \geq N) = 0,
\]

\[
(jj) \mathbb{E} \left[ 1 \wedge \sup_{0 \leq s \leq \varepsilon} |X^n_{t+s} - X^n_t|^\alpha \right] \leq b(\varepsilon), \quad \forall \varepsilon > 0, n \geq 1, t \in [0, T].
\]

Then the family \( \{X^n : n \in \mathbb{N}^*\} \) is tight in \( C(\mathbb{R}_+; \mathbb{R}^d) \).

Proof. We fix \( \varepsilon, T > 0 \). From \( (j) \), there exists \( M = M_{\varepsilon} \geq 1 \) such that

\[
\sup_{n \in \mathbb{N}^*} P( |X^n_0| \geq M) < \frac{\varepsilon}{2}.
\]

Let \( \gamma_k = \frac{1}{2(k-1)/\alpha} \) and \( \varepsilon_k \downarrow 0 \) be such that \( b(\varepsilon_k) \leq \frac{\varepsilon}{4k^2 T} \). Let \( N_k = \left\lfloor \frac{T}{\varepsilon_k} \right\rfloor \) and \( t_i = \frac{(i-1)T}{N_k} \).

Applying Theorem Arzelá–Ascoli we see that the set

\[
K_{\varepsilon} = \left\{ z \in C([0, T]; \mathbb{R}^d) : |z(0)| \leq M,
\sup_{1 \leq i \leq N_k} \sup_{0 < s \leq \varepsilon_k} |z(t_i + s) - z(t_i)| \leq \gamma_k, \forall k \in \mathbb{N}^* \right\}
\]

is compact in \( C([0, T]; \mathbb{R}^d) \).

From Markov’s inequality and \( (jj) \)

\[
P( X^n \notin K_{\varepsilon} ) \leq P( |X^n_0| > M ) + \sum_{k \in \mathbb{N}^*} \sum_{i=1}^{N_k} P \left( \sup_{0 \leq s \leq \varepsilon_k} |X^n_{t_i+s} - X^n_{t_i}| > \gamma_k \right)
\]

\[
< \frac{\varepsilon}{2} + \sum_{k \in \mathbb{N}^*} \sum_{i=1}^{N_k} \varepsilon_k \times b(\varepsilon_k) \frac{\gamma_k}{\gamma_k^\alpha} \leq \frac{\varepsilon}{2} + \sum_{k \in \mathbb{N}^*} \frac{N_k \times \varepsilon_k \times b(\varepsilon_k)}{\gamma_k^\alpha} \leq \varepsilon.
\]

The proof is complete now.
Proposition 46 Let $g : \mathbb{R}_+ \to \mathbb{R}_+$ be a continuous function satisfying $g(0) = 0$ and $G : C \left( \mathbb{R}_+ ; \mathbb{R}^d \right) \to \mathbb{R}_+$ be a mapping which is bounded on compact subsets of $C \left( \mathbb{R}_+ ; \mathbb{R}^d \right)$. Let $X^n, Y^n, n \in \mathbb{N}^*$, be random variables with values in $C \left( \mathbb{R}_+ ; \mathbb{R}^d \right)$. If $\{ Y^n : n \in \mathbb{N}^* \}$ is tight and for all $n \in \mathbb{N}^*$

\[
\begin{align*}
(i) \quad & |X^n_0| \leq G(Y^n), \text{ a.s.} \\
(ii) \quad & m_{X^n}(\varepsilon; [0, T]) \leq G(Y^n) g(m_{Y^n}(\varepsilon; [0, T])), \text{ a.s., } \forall \varepsilon, T > 0,
\end{align*}
\]

then $\{ X^n : n \in \mathbb{N}^* \}$ is tight.

Proof. Let $\delta > 0$ be arbitrary. Then there exists a compact set $K_\delta \subset C \left( [0, \infty[ ; \mathbb{R}^d \right)$ such that for all $n \in \mathbb{N}^*$

$$
P \left( Y^n \notin K_\delta \right) < \delta.
$$

Define $N_\delta = \sup_{x \in K_\delta} G(x)$. Then

$$
P \left( |X^n_0| > N_\delta \right) < \delta.
$$

Let $a > 0$ be arbitrary. There exists $\varepsilon_0 > 0$ such that

$$
\sup_{x \in K_\delta} \left[ g \left( m_x(\varepsilon; [0, T]) \right) \right] < \frac{a}{N_\delta}, \quad \forall 0 < \varepsilon < \varepsilon_0.
$$

Consequently for all $n \in \mathbb{N}^*$,

$$
P \left( m_{X^n}(\varepsilon; [0, T]) \geq a \right) \leq P \left[ g \left( m_{Y^n}(\varepsilon; [0, T]) \right) \geq \frac{a}{N_\delta}, Y^n \in K_\delta \right] + P \left( Y^n \notin K_\delta \right) \leq \delta
$$

and the result follows. \hfill \blacksquare

7.3 Itô’s stochastic integral

In this subsection we consider $\{ B_t : t \geq 0 \}$ to be a $k$–dimensional Brownian motion on a stochastic basis (which is supposed to be complete and right–continuous) $(\Omega, \mathcal{F}, \mathbb{P}, \{ \mathcal{F}_t \}_{t \geq 0})$.

Let $S_d[0, T]$ be the space of p.m.c.s.p. $X : \Omega \times [0, T] \to \mathbb{R}^d$ and $\Lambda_d(0, T)$ the space of p.m.c.s.p. $X : \Omega \times [0, T] \to \mathbb{R}^d$ such that

$$
\int_0^T |X_t|^2 dt < \infty, \text{ } \mathbb{P}–\text{a.s.}
$$

Write $S_d$ (and $\Lambda_d$) for space of p.m.c.s.p. $X : \Omega \times [0, T] \to \mathbb{R}^d$ such that the restriction of $X$ to $[0, T]$ belongs to $S_d$ (respectively to $\Lambda_d$).

If $X \in S_{d \times k}$ and $B$ is an $\mathbb{R}^k$–Brownian motion, then the stochastic process $\{ (X_t, B_t) : t \geq 0 \}$ can be seen as a random variable with values in the space $C(\mathbb{R}_+, \mathbb{R}^{d \times k}) \times C(\mathbb{R}_+, \mathbb{R}^k)$. The law of this random variable will be denoted $\mathcal{L}(X, B)$.

Proposition 47 (Corollary 2.13 in [25]) Let $X, \hat{X} \in S_d[0, T], B, \hat{B}$ be two $\mathbb{R}^k$–Brownian motions and $g : \mathbb{R}_+ \times \mathbb{R}^d \to \mathbb{R}^{d \times k}$ be a function such that

$$
g \left( \cdot, y \right) \text{ is measurable } \forall y \in \mathbb{R}^d,
$$

$$
y \mapsto g \left( t, y \right) \text{ is continuous } dt – \text{a.e.}
$$
If \( \mathcal{L}(X, B) = \mathcal{L}(\tilde{X}, \tilde{B}) \) on \( C(\mathbb{R}_+, \mathbb{R}^{d+k}) \), then
\[
\mathcal{L}(X, B, \int_0^T g(s, X_s) dB_s) = \mathcal{L}(\tilde{X}, \tilde{B}, \int_0^T g(s, \tilde{X}_s) d\tilde{B}_s) \text{ on } C(\mathbb{R}_+, \mathbb{R}^{d+k+d}).
\]

We present now a continuity property of the mapping \((X, B) \mapsto \int_0^T X_s dB_s\).

Given \( B : \Omega \times \mathbb{R}_+ \rightarrow \mathbb{R}^k \) and \( X : \Omega \times \mathbb{R}_+ \rightarrow \mathbb{R}^{d \times k} \) be two stochastic processes, let \( \mathcal{F}^B_t \mathcal{X} \) be the natural filtration generated jointly by \( B \) and \( X \).

For the proof of the next Proposition see Proposition 2.4 in [7] or Proposition 2.14 in [25].

**Proposition 48** Let \( B, B^n, \tilde{B}^n : \Omega \times \mathbb{R}_+ \rightarrow \mathbb{R}^k \) and \( X, X^n, \tilde{X}^n : \Omega \times \mathbb{R}_+ \rightarrow \mathbb{R}^{d \times k} \) be continuous stochastic processes such that

(i) \( \tilde{B}^n \) is \( \mathcal{F}^{	ilde{B}^n}_t, \tilde{X}^n \)-Brownian motion \( \forall \ n \geq 1 \);

(ii) \( \mathcal{L}(\tilde{B}^n, \tilde{X}^n) = \mathcal{L}(B^n, X^n) \) on \( C(\mathbb{R}_+, \mathbb{R}^k \times \mathbb{R}^{d \times k}) \), for all \( n \geq 1 \);

(iii) \( \int_0^T |X^n_s - X_s|^2 ds + \sup_{t \in [0, T]} |B^n_t - B_t| \rightarrow 0 \), in probability, as \( n \rightarrow \infty \), for all \( T > 0 \).

Then \( (B^n, \{ \mathcal{F}^B_t \mathcal{X} \}), n \geq 1 \), and \( (B, \{ \mathcal{F}^B_t \mathcal{X} \}) \) are Brownian motions and as \( n \rightarrow \infty \)
\[
\sup_{t \in [0, T]} \left| \int_0^t X^n_s dB^n_s \right| \rightarrow \left| \int_0^t X_s dB_s \right| \rightarrow 0 \text{ in probability.} \tag{46}
\]

### 7.4 A forward stochastic inequality

Let \( X, \tilde{X} \in S_d \) be two semimartingales defined by
\[
X_t = X_0 + K_t + \int_0^t G_s dB_s, \ t \geq 0, \quad \tilde{X}_t = \tilde{X}_0 + \tilde{K}_t + \int_0^t \tilde{G}_s dB_s, \ t \geq 0, \tag{47}
\]

where
\( \diamond \ K, \tilde{K} \in S_d \);
\( \diamond \ K_0(\omega), \tilde{K}_0(\omega) \in BV_{\text{loc}}(\mathbb{R}_+; \mathbb{R}^d), K_0(\omega) = \tilde{K}_0(\omega) = 0, \ P\text{-a.s.} \);
\( \diamond \ G, \tilde{G} \in \Lambda_{d \times k} \).

Assume that there exist \( p \geq 1 \) and \( \lambda \geq 0 \) and \( V \) a bounded variation p.m.c.s.p., with \( V_0 = 0 \), such that, as measures on \( \mathbb{R}_+ \),
\[
\langle X_t - \tilde{X}_t, dK_t - d\tilde{K}_t \rangle + \left( \frac{1}{2} m_p + 9p \lambda \right) |G_t - \tilde{G}_t|^2 dt \leq |X_t - \tilde{X}_t|^2 dV_t. \tag{48}
\]
Theorem 49 (Corollary 6.74 in [25]) Let $p \geq 1$. If the assumption (48) is satisfied with $\lambda > 1$, then there exists a positive constant $C_{p,\lambda}$ such that for all $\delta \geq 0, 0 \leq t \leq s$:

$$
\mathbb{E}^{\mathcal{F}_t} \frac{||e^{-V_t}(X_t - \hat{X}_t)||^p_{[t,s]} (1 + \delta^p||e^{-V_t}(X_t - \hat{X}_t)||_{2_{[t,s]}}^2)^{p/2}}{e^{-pV_t}||X_t - \hat{X}_t||^p_{[t,s]} (1 + \delta e^{-2V_t}||X_t - \hat{X}_t||^2_{[t,s]})^{p/2}} \leq C_{p,\lambda}, \quad \mathbb{P}-\text{a.s.}
$$

In particular for $\delta = 0$

$$
\mathbb{E}^{\mathcal{F}_t} ||e^{-V_t}(X_t - \hat{X}_t)||^p_{[t,s]} \leq C_{p,\lambda} e^{-pV_t}||X_t - \hat{X}_t||^p, \quad \mathbb{P}-\text{a.s.},
$$

for all $0 \leq t \leq s$.

As a consequence of the above theorem, since

$$
\frac{1}{2} (1 \wedge r) \leq \frac{r}{(1 + r^2)^{1/2}} \leq 1 \wedge r, \quad \forall r \geq 0,
$$

we obtain:

Corollary 50 If assumption (48) is satisfied with $\lambda > 1$ and $p \geq 1$, then there exists a positive constant $C_{p,\lambda}$ depending only on $(p, \lambda)$ such that $\mathbb{P} - \text{a.s.}$

$$
\mathbb{E}^{\mathcal{F}_t} \left[ 1 \wedge ||e^{-V_t}(X_t - \hat{X}_t)||^p_{[t,s]} \right] \leq C_{p,\lambda} \left[ 1 \wedge |e^{-V_t}(X_t - \hat{X}_t)|^p \right],
$$

for all $0 \leq t \leq s$.
