On the 29th of October 2018, one specimen of the spotted weever, *Trachinus araneus* measuring 47.3 cm in total length and weighting 968 g was captured by trammel net operating in Oran Bay (Kristel fishery) Western Algerian coast at 100 m depth. Up to date, this length is a new record of maximum length reached for this trachinid in the Mediterranean basin.

Key words: The spotted weever, *Trachinus araneus*, maximum size, Oran Bay, Mediterranean Sea

INTRODUCTION

The maximum observed length of individual of certain fish species is a useful information for a rapid evaluation of growth rates in the absence of basic data (LEGENDRE & ALBARET, 1991; FROESE and BINOHLAN, 2000; AKYOL et al., 2007). Maximum length and maximum weight are important theoretical parameters in fisheries science. Directly or indirectly, these measurements enter in most of the models used in stock assessments. In this sense, updating the maximum size of a species that might be commercially exploited in the future, gains importance (BORGES, 2001).

The spotted weever *Trachinus araneus* is a member of Trachinidae family found in the eastern Atlantic, from Morocco to southern Angola. Its range extends north into the Mediterranean, and along the Atlantic coast of Europe to southern Portugal (CARPENTER et al., 2015). It is particularly abundant in the eastern Mediterranean. It lives in the shallow waters on sandy and sandy-muddy detrital bottoms, up to about 100 m deep, burrowing into the substrate. It feeds on small fish and crustaceans (FROESE & PAULY, 2018).

It is a venomous species that commonly reaches between 10 and 30 cm in total length, with a maximum of 45 cm in the Mediterranean and between 15 to 20 cm with a maximum of 36 cm in the Black Sea (BAUCHOT and HUREAU, 1986).

It appears to be both common and abundant, particularly in the eastern Mediterranean. This species is taken as bycatch in demersal trawl fisheries and is sometimes marketed. This species is likely found in marine protected areas throughout its range. Therefore, *T. araneus* is assessed as Least Concern (CARPENTER et al., 2015).
Limited bibliography is available for *T. araneus* focusing mainly on envenomation (BEDINI et al., 2003; ERYILMAZ et al., 2006; SMITH and WHEELER, 2006; PORTILLO STREMPEL, 2009; ALPARSLAN et al., 2010, YILDIZ and KARAKULAK, 2018) or heavy metal contents (CABRERA et al., 1994; LÓPEZ et al., 2000 and BRAMBILLA et al., 2013). Up to date, no studies were conducted on this trachinid in Algerian waters. The aim of this paper is to present the maximum total length of the spotted weever *T. araneus* documented up to now in the Mediterranean.

**MATERIAL AND METHODS**

On the 29th of October 2018, one specimen of *T. araneus* (Fig. 1) measuring 47.3 cm in total length (TL) was captured by trammel net in Oran Bay (Kristel fishery) (35°49’36.0”N 0°32’30.7”W), on sandy bottom at a depth of 100 m (Fig. 2). *T. araneus* specimen was measured to the nearest millimeter and weighted to the nearest g then photographed. For otoliths (Fig. 3) measurements an electronic caliper (Digiroch) was used, unfortunately otoliths were too thick to be read directly under binocular microscope to determine the age of *T. araneus* specimen.

The specimen was identified using FAO species identification sheets (BAUCHOT and HUREAU, 1986; DJABALI et al., 1993) on the basis of the following morphological characters: the body elongated and compressed; very small eyes located near the dorsal profile of the head; very oblique large mouth, with maxillary extending slightly beyond the posterior edge of the eye; villiform teeth; presence of 2 strong venomous spines on the operculum, 2 spines on the anterodorsal edge of the orbit and 6 dorsal spines in the first dorsal fin, the second dorsal fin contains 29 soft rays and the anal fin counts 27; the back and flanks yellowish gray, with 9 dorsal brownish to blackish spots and, beneath the lateral line, an alignment of large, more or less rounded or quadrangular spots; black dorsal fin; caudal fin lined with black and with some dark spots.

RESULTS AND DISCUSSION

Measurements and percentage of each body part and otolith measurements are reported in relation to total length and are given in Table 1.

Table 1. Morphometric measurements as percentage of total length (%TL) of Trachinus araneus caught in Oran Bay, Western Mediterranean Sea

| Morphometric characteristic       | Measurement (cm) | Proportion (%) |
|----------------------------------|------------------|----------------|
| Total length (TL)                | 47.283           | 100.00         |
| Fork length (FL)                 | 45.837           | 96.94          |
| Standard length (SL)             | 41.21            | 87.16          |
| Pectoral fin length (LP)         | 6.992            | 14.79          |
| Ventral fin length (LV)          | 3.585            | 7.580          |
| Pre-ventral fin distance (PVD)   | 5.623            | 11.89          |
| Cephalic length (LC)             | 7.258            | 15.35          |
| Post-orbital distance (PO1)      | 5.859            | 12.39          |
| Eye diameter (O)                 | 0.705            | 1.490          |
| Post-orbital distance (POD2)     | 3.084            | 6.520          |
| Pre-pectoral distance (PPD)      | 9.861            | 20.86          |
| Maxillary length (LM)            | 2.722            | 5.760          |
| Anal fin length (LA)             | 27.08            | 57.27          |
| Pre-anal fin distance (PAD)      | 11.38            | 24.07          |
| Minimum body height (TPC)        | 2.650            | 5.600          |
| Maximum body height (T)          | 9.080            | 19.20          |
| Total weight (TW, g)             | 0.968            | -              |
| Otoliths measurements            | Right | Left |
| Total length                     | 1.470            | 1.488          |
| Wide                             | 0.727            | 0.743          |
| Total weight (g)                 | 0.338            | 0.345          |

Comparing our findings to those of MOUTOPOULOS and STERGIOU (2002), fork length represented 95.13% from total length and standard length represented 87.33% of total length of T. araneus from Greek waters which is close to our results with fork length representing 96.94% from total length and standard length representing 86.16% of total length. In an unpublished observation for the same species in Philippines, REYES in FROESE and PAULY, 2018 proportions of different body parts reported to total length were the same as our findings except two parameters, Pre-ventral distance represented 15.3% while we found 11.89%, and Head length represented 23.4% while we found only 15.35% for T. araneus caught in Oran Bay.

For Atlantic waters, maximum length recorded for T. araneus was 45 cm (SL) (ROUX, 1990 in QUÉRO et al., 1990), the same length (standard length) was assumed by CARPENTER et al., 2015. Central Mediterranean basin recorded a specimen in Greece (Table 2) measuring 39 cm TL and weighting 490.75 g while in Turkey one specimen was caught measuring 31 cm and weighting 230 g in 2006 (KARAKULAK et al., 2006). The maximum length ever recorded for Turkish and Mediterranean waters (40.8 cm TL and weighting 758 g) was reported by OZTEKIN et al., 2016.

Table 2. Maximum length records of Trachinus araneus given by several authors

| Location                      | TL (cm) | TW(g)  | References          |
|-------------------------------|---------|--------|---------------------|
| Aegean Sea (Greece)           | 39.0    | 490.75** | MOUTOPOULOS and STERGIOU, 2002 |
| Aegean Sea (Turkey)           | 31.0    | 230.00  | KARAKULAK et al., 2006 |
| Gallipoli peninsula, Turkey   | 40.8    | 758.00  | OZTEKIN et al., 2016 |
| North Eastern Atlantic        | 40*     | -      | HUREAU et al., 1979 |
| Eastern tropical Atlantic    | 45*     | -      | ROUX, 1990 in QUÉRO et al., 1990 |
| Oran Bay                      | 47.3    | 968.00  | Present study       |

*Standard length (SL) **calculated from LWR (Length weight relationship)

CONCLUSIONS

The maximum size found for the spotted weever T. araneus (47.3 cm, 968 g) caught in Oran Bay can be considered as a new maximum length for this species in Algerian and Mediterranean waters.
ACKNOWLEDGEMENTS

The author is very grateful to fishermen of Kristel Fishery and especially to Mr. Mokhtar. This paper is dedicated to the memory of Professor Ahmed BensaLha-Talet, my beloved father and mentor, who was an Algerian marine biologist. He worked more than 49 years and was dedicated to science. He was also Dean of Faculty of Natural sciences and life at University Oran 1 Ahmed BenBella (2012-2020). He passed away on 31st July 2020 (December, 1st 1946 – July, 31st 2020)

Nova maksimalna dužina pauka crnca, *Trachinus araneus* Cuvier, 1829 (Perciformes: Trachinidae) iz zapadnog Mediterana, zaljev Oran

Lotfi BENSAHLA-TALET i Ahmed BENSAHLA-TALET

SAŽETAK

Dana 29. listopada 2018. g. ulovljen je jedan primjerak pauka crnca, *Trachinus araneus* Cuvier, čija je totalna dužina iznosila 47,3 cm, a masa 968 grama. Primjerak je ulovljen na dubini od 100 m u zaljevu Oran (zapadna alžirska obala).
Ovo je dosada najveća zabilježena dužina za ovu vrstu u mediteranskom bazenu.

**Ključne riječi:** pauk crnac, *Trachinus araneus* Cuvier, maksimalna veličina, zaljev Oran, Sredozemno more
