Abstract: This paper presents an external-cavity dual-wavelength mid-infrared multiple optical parametric oscillator based on a single MgO:APLN crystal, which is pumped by a pulsed 1.064 µm laser. The output power and beam qualities of parametric lasers at different repetition rates and transmittance were studied. When the pump power of the 1.064 µm laser was 34.5 W, the repetition rate was 63 kHz, the maximum output powers of 2.79 W@3.30 µm and 4.92 W@3.84 µm were obtained with the transmittance T = 60%@1.57 µm, corresponding to optical–optical conversion efficiencies of 8.1% and 14.3%, respectively. Meanwhile, the beam qualities of two mid-infrared laser beams were effectively optimized and the pulse widths of 9.72 ns@3.30 µm and 9.67 ns@3.84 µm were obtained synchronously.

Keywords: mid-infrared laser; multiple optical parametric oscillator; dual-wavelength

1. Introduction

The dual-wavelength lasers in the range of 3–5 µm have versatile applications such as military confrontation and laser radar [1,2]. A multiple optical parametric oscillator (MOPO) is an effective way to obtain a multi-wavelength tunable laser in the same spectral region [3–7]. However, due to the multiple frequencies and complex energy conversion path in the process of synchronous oscillation, which produces the gain competition of the multiple parametric outputs easily, this can result in power distribution imbalance, beam quality deterioration, spectrum broadening, and so on [8–14]. In 2015, Yu et al. demonstrated a straight cavity MOPO using an aperiodically poled MgO:LN(MgO:APLN). The 1.57 µm and 3.84 µm cross period resonant outputs were realized through a single polarized crystal with the output power of 2.4 W@1.57 µm and 1.31 W@3.84 µm [15,16]. In 2020, the college of Advanced Interdisciplinary Studies from National University of Defense Technology used a traditional Raman fiber oscillator as a dual-wavelength pump source, the output power of 2 W@3.27 µm and 4.98 W@3.66 µm were achieved [17,18]. In this study, an external-cavity pumped high repetition rate MOPO based on a single MgO:APLN crystal is reported. The gain competition in the process of MOPO under different repetition rates and transmittance is experimentally demonstrated. Moreover, the output power of dual-wavelength mid-infrared is maximized by selecting the repetition rate and transmittance @1.57 µm. When the pump power of the 1.064 µm laser was 34.5-W, the repetition rate was 63 kHz, the maximum output powers of 2.79 W@3.30 µm and 4.92 W@3.84 µm were obtained with the transmittance T = 60%@1.57 µm, corresponding...
to optical–optical conversion efficiencies of 8.1% and 14.3% and quantum efficiencies of 32.24% and 27.71%, respectively.

2. Materials and Methods

The experimental setup of the external cavity MgO:APLN-MOPO is shown in Figure 1. The pump source of the MOPO was an AO Q-switched Nd:YVO₄ laser working at 1.064-μm, the maximum output power was 40 W with the pulse width of 9.86 ns@60 kHz. The laser crystal was an adhesive-free bond a-cut YVO₄/Nd:YVO₄ crystal with 0.25 at% Nd concentration. Its cross section was 3 mm × 3 mm, and it consisted of a 16 mm Nd³⁺-doped YVO₄ and two 4 mm pure YVO₄. The output 1.064 μm laser was converted to linear polarization after the polarizer. An optical isolator and a half-wave plate (HWP) were used to isolate the 1.064 μm laser returning to the pump source, and the laser was focused into the MgO:APLN crystal by a convex lens with a focal length of 150 mm. To eliminate the walk-off effect between the beams, we used the maximum nonlinear coefficient d₃₃ of the MgO:APLN crystal. The multiple OPO cavity consisted of M₁, a beam splitter (BS), and a concave mirror M₂; the parameters of the cavity mirror coating are listed in Table 1.

In a previous study, we designed an aperiodically poled MgO:LN (MgO:APLN) domain structure for two-phase mismatch compensation; the phase mismatch and the polarization structure is shown in Figure 2 and the inset, respectively. The superlattice was customized and produced by the HCP company, which provided two inverted lattice vectors for the MgO:APLN crystal [19,20]. According to the Fourier transform, the Fourier coefficients corresponding to the two-phase mismatch compensation ΔK were 0.41 and 0.42, respectively, which provided an effective inverse lattice vector of (1.57 μm, 3.30 μm) and (1.47 μm, 3.84 μm) pumped by 1.06 μm. The 5% MgO-doped APLN, as the nonlinear medium, was placed in the OV50 thermostat, and the temperature was maintained at 25 °C.

The MgO:APLN crystal dimension was 50 mm × 3 mm × 3 mm, and both ends of the faces were anti-reflection coated at 1.06 μm, 1.4~1.7 μm, and 3.1~4.2 μm.

| M2              | CaF₂     | 3.1~4.2 μm@HT, R = −150 mm |
3. Results

According to the above experimental parameters, the output characteristics of MOPO at different repetition rates were studied with the transmittance of M1 of 40% and the maximum pump power of 34.5 W (measured by a power meter of OPHIR F150A-BB-26-PPS). We used the Fourier spectrometer (ARCoptix, wavelength range from 1 µm to 5.6-µm, spectral resolution of 0.01 ppm with linewidth < 10 GHz) produced by American Thorlabs Company; the wavelength was synchronously collected at 3.3 µm and 3.8 µm, when the repetition rate changed from 20 to 100 kHz, corresponding to the wavelength of the near-infrared output at 1.47 µm and 1.57 µm, respectively. The mid-infrared laser spectrum with a repetition rate of 100 kHz is shown in Figure 3. Note that when the repetition rate changed from 20 to 100 kHz, the output wavelength and linewidth showed no obvious variation.

The measured maximum output power of the dual-wavelength mid-infrared lasers when the repetition rate changed from 20 to 100 kHz is shown in Figure 4. As can be observed, the power of the 3.84 µm mid-infrared laser increased gradually with the enhancement of repetition rate; when the repetition rate was 63 kHz, the maximum output powers of 2.11 W@3.3 µm and 4.49 W@3.84 µm were obtained, and the mid-infrared total power was 6.6-W, corresponding to the optical–optical conversion efficiency of 19.1%. With
the continuous increase in repetition rate, the power of the 3.84 µm mid-infrared laser decreased gradually, and the gain competition of two parameter outputs in the cavity became more and more intense; however, for the 3.3 µm laser, the change in repetition rate had a gentle effect on its output power. When the repetition rate was less than 10 kHz or higher than 110 kHz, the 3.84 µm was not achieved throughout the process because the parametric optical gain of OPO1 (1.57 µm, 3.30 µm) was higher than that of OPO2 (1.47 µm, 3.84 µm) in the process of multiple optical parametric oscillation and energy conversion. The unbalanced output powers between 3.30 µm and 3.84 µm were caused by fierce gain competition and reversal conversion in a cavity.

![Figure 4](image-url)

**Figure 4.** The output power of mid-infrared lasers at different repetition rates. (a) The output power of mid-infrared lasers @20~100 kHz. (b) The total power of dual-wavelength @60~70 kHz.

We used a pyroelectric array camera (OPHIR PyrocamIII) to measure the exit beam distribution of 3.30 and 3.84 µm. Figures 5 and 6 show the output power and beam qualities of two mid-infrared lasers at different repetition rates. When the repetition rate was 63 kHz, the maximum power of two mid-infrared outputs was realized; meanwhile, the slope efficiency was improved with an increase in the pump power, which proves that under the modulation of the optimal repetition rate, the gain obtained by the two parameter lasers oscillation process was optimally distributed, and the problem of gain competition was
effectively solved. It can be seen that choosing the appropriate repetition rate can improve the conversion efficiencies and beam qualities of the mid-infrared outputs.

![Figure 5. Power curve and beam qualities at different repetition rates.](image1)

Based on the above experiments, the characteristics of mid-infrared parametric outputs by changing the transmittance@1.57 µm of M1 were studied. The output power of dual-wavelength mid-infrared lasers is shown in Figure 7 when the transmittance@1.57-µm changed from 0 to 99%. As can be seen from this figure, under the low transmittance of the M1, the 3.84 µm laser had a smaller effective gain. As the transmittance of the 1.57 µm laser increased, the oscillation process of the 3.84 µm laser enhanced gradually. When the transmittance of the M1 was 60%@1.57 µm, the output power of 4.92 W@3.84 µm and 2.786 W@3.3 µm was achieved, and the total power of mid-infrared laser was increased to 7.71 W. With the continuous increase in transmittance, the output power of the two mid-infrared beams decreased gradually, indicating that they had reached the gain saturation state at this time. This proved that by changing the transmittance@1.57 µm, most of the signal light was emitted from the output mirror, which decreased the accumulation of parametric outputs and reduced the power density in the cavity, inhibited the occurrence of

![Figure 6. Output power and beam quality at 63 kHz.](image2)
back conversion, and improved the conversion efficiency. Selecting the best transmittance can effectively balance the gain distribution of the two parametric beams.

Figure 7. The output power of mid-infrared lasers under different transmittance. (a) The output power of mid-infrared lasers under different transmittance. (b) The total power of dual-wavelength under different transmittance.

The power curve, beam qualities, and pulse width of dual-wavelength mid-infrared outputs were measured with the repetition rate of 63 kHz and the transmittance $T = 60\%@1.57\mu m$; the results are shown in Figures 8 and 9. As shown in Figure 8, by selecting the optimal transmittance of the M1, the power of the two mid-infrared outputs was further improved. At the same time, the exit beam quality was significantly optimized due to the balance of the gain competition between the two parametric lasers. The pulse widths of 9.72-ns@3.30 μm and 9.67 ns@3.84 μm were measured by a HgCdTeZn infrared detector (PCI3TE-12) and oscilloscope (MDO3054, Tektronix) synchronously, after splitting the output mid-infrared lasers under the maximum output power.
4. Conclusions

In sum, we experimentally demonstrated an external-cavity pumped high repetition rate MOPO based on a MgO:APLN crystal. The influence of gain competition on OPO output powers and beam qualities was investigated, and the gain competition in the process of MOPO under repetition rate and transmittance was also analyzed experimentally. It was found that the inhomogeneous distribution of laser intensity reduced the conversion efficiencies and deteriorated the beam qualities, and the gain competition of two pairs of parametric waves was balanced by selecting the best repetition rate and output mirror transmittance; the power density in the cavity was reduced, the occurrence of back conversion was inhibited, and the conversion efficiencies of the mid-infrared wavelength were improved. When the maximum pump power of 1.064 µm laser was 34.5 W and the repetition rate was 63 kHz, the maximum output powers of 2.79 W@3.30 µm and 4.92 W@3.84 µm were obtained with the transmittance T = 60%@1.57 µm, corresponding to conversion efficiencies of 8.1% and 14.3% and quantum efficiencies of 32.24% and 27.71%, respectively.
