Bulk gravitational field and dark radiation on the brane in dilatonic brane world

Hiroyuki Yoshiguchi and Kazuya Koyama

Department of Physics, University of Tokyo 7-3-1 Hongo, Bunkyo, Tokyo 113-0033, Japan

We discuss the connection between the dark radiation on the brane and the bulk gravitational field in a dilatonic brane world model proposed by Koyama and Takahashi where the exact solutions for the five dimensional cosmological perturbations can be obtained analytically. It is shown that the dark radiation perturbation is related to the non-normalizable Kaluza-Klein (KK) mode of the bulk perturbations. For the de Sitter brane in the anti-de Sitter bulk, the squared mass of this KK mode is $2H^2$ where $H$ is the Hubble parameter on the brane. This mode is shown to be connected to the excitation of small black hole in the bulk in the long wavelength limit. The exact solution for an anisotropic stress on the brane induced by this KK mode is found, which plays an important role in the calculation of cosmic microwave background radiation anisotropies in the brane world.

PACS numbers:

I. INTRODUCTION

In the past few years, a lot of efforts have been devoted to the investigation of the brane world scenario, where our Universe is a hypersurface, called a brane, embedded in a higher dimensional bulk spacetime. Especially, models proposed by Randall and Sundrum have attracted much attention in the context of gravity and cosmology [1-3]. In their second model (RS model), a positive tension brane is embedded in five-dimensional anti-de Sitter (AdS) spacetime. The standard model particles are confined to the brane while the gravity can propagate in the bulk. An interesting feature of their model is that four-dimensional gravity can be recovered at low energy despite the infinite size of the extra dimension. It breaks the conventional idea that the extra dimension must be compact and small. The extension of the RS model to dilatonic brane worlds have been intensively investigated [4-11].

When we discuss the gravity on the brane, it is useful to derive the effective four-dimensional Einstein equation on the brane firstly developed by Shirozumi, Maeda, and Sasaki [4-17]. The effective four-dimensional Einstein equation includes the term $E_{\mu\nu}$ that is the electric part of five-dimensional Weyl tensor. This term is induced by the gravitational field in the bulk and carries the information in the bulk. In the RS model with AdS bulk spacetime, $E_{\mu\nu}$ tensor can induce "dark radiation" on the brane in the homogeneous and isotropic background spacetime. It has been realized that the appearance of the dark radiation on the brane is related to the existence of the black hole in the bulk.

The dark radiation provides interesting phenomena in the brane world cosmology. First, it modifies the expansion of the background universe in the same way as an usual radiation [12-15]. Secondly, it also gives important effects on cosmological perturbations on the brane. The cosmological perturbations in brane world have been actively discussed [19-26] and the possible impact on cosmic microwave background (CMB) anisotropies of the dark radiation perturbation is discussed [26-28]. In this paper, we focus our attention to the dark radiation in cosmological perturbations.

The difficulty in the calculation of dark radiation perturbation is that it is no longer the radiation fluid once we consider the perturbation. This is because $E_{\mu\nu}$ could have a non-trivial component of an anisotropic stress. This renders distinguishable features to the dark radiation perturbation from an usual radiation fluid.

Because $E_{\mu\nu}$ is determined by the bulk gravitational field, it cannot be determined solely by the four-dimensional equations on the brane in general. Nevertheless, it is possible to know some features of this tensor by using constraint equations on the brane obtained by the four-dimensional Bianchi identity. In the background spacetime, the four-dimensional equations are sufficient to show that $E_{\mu\nu}$ induces the radiation fluid on the brane. In order to determine the amplitude of the energy density of dark radiation, the information in the bulk, that is, the mass of the black hole in the bulk is needed. In the case of the perturbations, it is impossible to determine the anisotropic component of $E_{\mu\nu}$ only from the four-dimensional equations. It is needed to calculate the perturbations in the bulk.

The attempt to connect the dark radiation perturbation on the brane to the bulk perturbations was made in the Ref. [26]. However, in the RS model, it is impossible to find the analytic solutions for the bulk perturbations that properly satisfy the junction conditions at the brane. Then it is difficult to analyze the precise relation between the dark radiation perturbation and the bulk perturbations.

In this paper, we use a model provided by Koyama and Takahashi [24, 30]. This model is proposed in the context of an inflationary brane model induced by a bulk scalar field [31-36]. The great advantage of this model is that the five dimensional cosmological perturbations can be solved analytically. Very recently, Kobayashi and Tanaka introduced a $(5 + m)$-dimensional vacuum description of this model that makes the analysis of cosmological perturbation simple [37]. They found the complete sets of the solutions for bulk perturbations. The main purpose of this paper is to clarify the connection between the dark radiation perturbation and bulk perturbations in
the bulk in this exactly solvable model.

The plan of this paper is as follows. In Sec.II we briefly review the background spacetime. We then derive the four-dimensional effective Einstein equations and the equation of motion for the scalar field on the brane in Sec.III. In the dilatonic brane world, $E_{\mu\nu}$ contains the contribution from the bulk scalar field. In order to make it easy to compare our analysis with the one in the RS model, we separate the contribution from the bulk scalar field in $E_{\mu\nu}$ and define a new tensor $F_{\mu\nu}$ which contains the information of the bulk gravitational fields. In Sec.V we discuss the “dark radiation” in cosmological perturbations on the brane. First, we find the dark radiation like solution for the constraint equations for $F_{\mu\nu}$ obtained by the four-dimensional Bianchi identity. We also calculate the exact solutions for $F_{\mu\nu}$ using the solutions of the bulk gravitational field obtained in [26, 31, 37]. Then comparing these two results, it is possible to identify the bulk perturbation that induces the dark radiation like contributions on the brane. In Sec.VI we discuss the connection between this bulk perturbation and the excitation of perturbatively small black hole in the bulk. In Sec.VII we summarize the results and discuss the anisotropic stress induced by the dark radiation perturbation and its implication for the CMB anisotropies.

II. BACKGROUND SPACETIME

We first review the background spacetime [24, 30]. We start from the five-dimensional Einstein-Hilbert action with a bulk scalar field,

$$S = \int d^5x \sqrt{-g_5} \left( \frac{1}{2\kappa^2} R - \frac{1}{2} \partial_\mu \phi \partial^\mu \phi - \Lambda(\phi) \right)$$

where $\kappa^2$ is five-dimensional gravitational constant. The potential for the scalar field in the bulk and on the brane are taken to be exponential:

$$\kappa^2 \Lambda(\phi) = \left( \frac{\Delta}{8} + \delta \right) \lambda^2_0 e^{-2\sqrt{2b}\kappa \phi},$$

$$\kappa^2 \lambda(\phi) = \sqrt{2\lambda^2_0} e^{-\sqrt{2b}\kappa \phi}. \quad (2)$$

Here $\lambda_0$ is the energy scale of the potential, $b$ is the dilaton coupling and we defined

$$\Delta = 4b^2 - \frac{8}{3}. \quad (3)$$

We assume the $Z_2$ symmetry across the brane. This type of scalar field arises from a sphere reduction in M theory or string theory.

For $\delta = 0$, the static brane solution was found [31]. The existence of the static brane requires tuning between bulk potential and brane tension known as Randall-Sundrum tuning. It has been shown that for $\Delta \leq -2$, we can avoid the presence of the naked singularity in the bulk and also ensure the trapping of the gravity. The reality of the dilaton coupling requires $-8/3 \leq \Delta$. Thus in the rest of the paper we shall assume $-8/3 < \Delta < -2$.

For $\Delta = 8/3$, we recover the Randall-Sundrum model. The value of $\delta$ represents a deviation from the Randall-Sundrum tuning. This deviation drives an inflation on the brane.

The solution for background spacetime is found as

$$ds^2 = e^{2W(y)} \left( -dt^2 + e^{2\alpha(t)} \delta_{ij} dx^i dx^j + e^{2\sqrt{2b}\kappa \phi(t)} dy^2 \right),$$

$$\varphi(t, y) = \varphi(t) + \Xi(y). \quad (5)$$

The evolution equations for $\alpha(t)$ and $\varphi(t)$ are given by

$$\dot{\alpha} + \sqrt{2b}\kappa \dot{\phi} = \frac{1}{6} \kappa^2 \dot{\varphi}^2 - \frac{1}{3} \lambda^2_0 \frac{\Delta}{8} + \delta e^{-2\sqrt{2b}\kappa \phi},$$

$$\dot{\varphi} + 3\dot{\alpha} + \sqrt{2b}\kappa \dot{\phi} = -4\sqrt{2b}\kappa^{-1} \lambda^2_0 \frac{\delta}{\Delta} e^{-2\sqrt{2b}\kappa \phi}, \quad (6)$$

where dot denotes the derivative with respect to $t$.

The solution for $\alpha(t)$ and $\varphi(t)$ can be easily found as

$$e^{\alpha(t)} = (H_0 t)^{\frac{\Delta}{12 + 3\delta}}, \quad e^{\varphi(t)} \approx (H_0 t)^{\frac{\Delta + 8/3}{12 + 3\delta}}.$$

and a conformal time $\eta$ is defined as

$$\eta = \int e^{-\alpha} dt = \frac{3\Delta + 8}{3(\Delta + 2)} H_0^{-\frac{1}{12 + 3\delta}} t^{\frac{3(\Delta + 2)}{12 + 3\delta}}.$$ (11)

We should notice that power-law inflation occurs on the brane for $-8/3 < \Delta < -2$.

The solutions for $W(y)$ and $\Xi(y)$ can be written as

$$e^{W(y)} = \mathcal{H}(y)^{\frac{\Delta}{12 + 3\delta}}, \quad e^{\kappa \Xi(y)} = \mathcal{H}(y)^{\frac{\Delta + 8/3}{12 + 3\delta}}, \quad (12)$$

where

$$\mathcal{H}(y) = \frac{\sinh H y}{\sinh H y_0}, \quad \sinh H y_0 = \frac{1}{\sqrt{1 - \frac{\Delta}{8}}}. \quad (13)$$

Here we assumed $\frac{\Delta}{8} + \delta < 0$.

The above five-dimensional solution can be obtained by a coordinate transformation from the metric

$$ds^2 = e^{2P(z)}(dz^2 + dt^2 + \delta_{ij} dx^i dx^j), \quad e^{\kappa \varphi(z)} = e^{3\sqrt{2b}p(z)}, \quad (14)$$

where

$$e^{P(z)} = (\sinh H y_0)^{-\frac{\Delta + 8/3}{12 + 3\delta}} (H z)^{\frac{3(\Delta + 2)}{12 + 3\delta}}. \quad (15)$$
by
\[ z = -\eta \sinh(Hy), \]
\[ \tau = -\eta \cosh(Hy). \]  
(16)

The metric Eq. (14) is often convenient because of its simplicity. (In the section V) we calculate the behavior of five-dimensional Weyl tensor in the presence of perturbatively small mass of black hole in the bulk not directly in Eq. (5) but in Eq. (14).

The background equations on the brane Eq.(6) and (7) can be described by the four-dimensional Brans-Dicke theory developed in [5, 16]. Using the Gauss equation equations on the brane using the covariant curvature formalism developed in [5, 16]. Using the Gauss equation

\[ S_{4, eff} = \frac{1}{2\kappa_4^2} \int d^4x \sqrt{-g_4} \left[ \varphi_{BD} \delta R - \frac{\omega_{BD}}{\varphi_{BD}} (\partial_\varphi_{BD})^2 \right] - \int d^4x \sqrt{-g_4} V_{eff}(\varphi_{BD}), \]  
(17)

where

\[ \varphi_{BD} = e^{2b\kappa_5}, \quad \omega_{BD} = \frac{1}{2b^2}, \]
\[ \kappa_4^2 V_{eff}(\varphi_{BD}) = -\lambda_0^2 \frac{\Delta + 4}{\Delta} \varphi_{BD}. \]  
(18)

III. EFFECTIVE EQUATIONS ON THE BRANE

In this section, we derive the effective gravitational equations on the brane using the covariant curvature formalism developed in [2, 10]. Using the Gauss equation and the Israel’s junction condition, we obtain the induced four-dimensional Einstein equations on the brane as

\[ (4)G_{\mu\nu} = -(4)\Lambda q_{\mu\nu} + \frac{2}{3}\kappa_2^2 T_{\mu\nu}^{(b)} - E_{\mu\nu}. \]  
(19)

where

\[ T_{\mu\nu}^{(b)} = D_\mu \varphi D_\nu \varphi - \frac{5}{8} q_{\mu\nu} (D_\varphi)^2, \]  
(20)

\[ (4)\Lambda = \frac{\kappa_2^2}{2} \left[ \Lambda + \frac{\kappa_2^2}{6} \lambda^2 - \frac{1}{8} \left( \frac{d\lambda}{d\varphi} \right)^2 \right], \]
\[ = \frac{\delta}{2} \lambda_0^2 e^{-2\sqrt{2b}\kappa_5} \varphi, \]  
(21)

and

\[ E_{\mu\nu} = (5)C_{\alpha\beta\sigma\tau} n^\alpha n^\beta. \]  
(22)

We defined \( D_\mu \) as the covariant derivative with respect to the induced metric on the brane. We note that four-dimensional cosmological constant \( (4)\Lambda \) is proportional to \( \delta \), which represents a deviation from the Randall-Sundrum tuning. The 4-dimensional gravitational equation on the brane Eq. (19) includes the projected Weyl tensor \( E_{\mu\nu} \), which can not be determined without solving the bulk dynamics in general. This term plays an essential role when we consider the cosmological perturbations in brane world models. Taking the divergence of the four-dimensional effective equations and using four-dimensional Bianchi identity, we obtain the constraint equations for \( E_{\mu\nu} \) as

\[ D^\mu E_{\mu\nu} = \frac{2\kappa_2^2}{3} D^\mu T_{\mu\nu}^{(b)} - D^\mu (4)\Lambda q_{\mu\nu}. \]  
(23)

Because \( E_{\mu\nu} \) contains the contribution from the bulk scalar field, it is convenient to separate the contributions of the bulk scalar field from \( E_{\mu\nu} \). We define

\[ -E_{\mu\nu} = \sqrt{2b}\kappa_5 \left( D_\mu \varphi D_\nu \varphi - q_{\mu\nu} (D_\varphi)^2 \right) - \frac{\kappa_2^2}{3} \left( D_\mu \varphi D_\nu \varphi - \frac{1}{4} q_{\mu\nu} (D_\varphi)^2 \right) + \frac{6b^2}{\Delta} \lambda_0^2 \delta e^{-2\sqrt{2b}\kappa_5} q_{\mu\nu} + F_{\mu\nu}, \]  
(24)

We also rewrite the the equation of motion for the scalar field on the brane as

\[ D^2 \varphi + \sqrt{2b}\kappa_5(D_\varphi)^2 - 4\sqrt{\frac{b}{\kappa}} \lambda_0^2 \delta e^{-2\sqrt{2b}\kappa_5} = F_\varphi. \]  
(25)

From traceless condition of \( E_{\mu\nu}, F_{\mu\nu}^\mu \) are related to \( F_\varphi \) as

\[ F_{\mu\nu}^\mu = 3\sqrt{2b}\kappa_5 F_\varphi. \]  
(26)

The equations derived from the effective action Eq.(17) agree with Eqs. (24), (25) with \( F_{\mu\nu} = 0 \) and \( F_\varphi = 0 \). Thus \( F_{\mu\nu} \) and \( F_\varphi \) are expected to describe the contribution of KK modes. It should be noted that a similar decomposition of \( E_{\mu\nu} \) was considered in Ref. [35].

Substituting the expression for \( E_{\mu\nu} \) Eq. (24) and using the equation of motion for the scalar field Eq. (25), we can rewrite the 4D Bianchi identity Eq. (23) as

\[ D^\mu F_{\mu\nu} + \sqrt{2b}\kappa_5 D_\nu \varphi F_{\mu\nu} = -\kappa_2^2 D_\nu \varphi F_\varphi. \]  
(27)

In general, this constraint equation is not sufficient to completely determine the behavior of \( F_{\mu\nu} \) and \( F_\varphi \) on the brane.

IV. DARK RADIATION IN COSMOLOGICAL PERTURBATIONS

In this section, we consider the dark radiation in cosmological perturbations on the brane. Since the dark radiation corresponds to scalar type perturbations, we restrict our attention to cosmological perturbations of this type throughout the paper. It is assumed \( F_{\mu\nu} = 0 \) and \( F_\varphi = 0 \) for the background spacetime in Koyama-Takahashi model.

First, we show that the dark radiation appears as a solution of the constraint equations for \( \delta F_{\mu\nu} \) and \( \delta F_\varphi \) on the brane Eq. (27) at large scales in the section IV A.
δF_{\mu\nu} and δF_{\varphi} have four independent variables for scalar perturbations. We also show that two of the four variables can not be determined by their constraint equations Eq. (27).

Next, we calculate the exact solution of δF_{\mu\nu} and δF_{\varphi} using the solutions for the five-dimensional perturbed Einstein equations obtained by \cite{29,30,37} in the section \[VI\]. We then investigate the relation between the dark radiation and the bulk perturbations.

A. View from the brane

Here we consider the dark radiation as a solution of the constraint equations for δF_{\mu\nu} and δF_{\varphi} on the brane Eq. (27). First of all, we expand δF_{\mu\nu} in terms of the scalar harmonics as

δF_{\mu\nu} = \rho_F Y_{\mu\nu} \delta\rho_F + \phi_{\mu\nu} \delta\phi_F + \pi_{\mu\nu} \delta\pi_F + \mathcal{E}_{\mu\nu} \delta\mathcal{E}_F,

where Y_{\mu\nu} is the normalized scalar harmonics and \rho_F, \phi_{\mu\nu}, \pi_{\mu\nu}, and \mathcal{E}_{\mu\nu} are the effective scalar, vector, traceless tensor, and bulk for scalar type perturbations. One of them corresponds to the scalar field and the other to the graviscalar. To investigate the relation between the dark radiation and the bulk perturbations, we need to obtain the exact solutions for δF_{\mu\nu} and δF_{\varphi}. This can be achieved only when we solve the bulk gravitational field and determine the behavior of the two unknown variables.

B. View from the bulk

In the previous subsection, we showed that we must solve the bulk gravitational field in order to completely determine the contributions of F_{\mu\nu} and F_{\varphi} to cosmological perturbations on the brane. Here, we first summarize the two independent solutions of five-dimensional Einstein equations for scalar perturbations obtained in \cite{37} in Sec \[VI.B.1\]. Using these solutions, we then calculate and investigate the behavior of the contributions of F_{\mu\nu} and F_{\varphi} to cosmological perturbations on the brane in Sec \[VI.B.2\]. Finally we discuss their relation to the dark radiation in Sec \[VI.B.3\].

1. Solutions of the bulk gravitational field

Here, we present the two independent solutions of five-dimensional Einstein equations for scalar perturbations obtained in \cite{37}. The perturbed metric and scalar field are given by

\begin{align}
\delta F^\alpha_{\mu\nu} = e^{2w(y)} & \left[ e^{2v(y)}(1 + 2NY) + 2AY dt dy \right. \\
& \left. - (1 + 2w'(y)) + e^{2\omega(t)} (1 + 2W) d\xi^i dx^j \\
& + 2EY_{ij} dx^i dx^j + 2BY_{ij} dx^i dt + 2CY_{ij} dx^i dy \right], \\
\varphi = & \varphi(t) + \Xi(y) + \delta\varphi Y.
\end{align}

We note that any gauge condition is not imposed here. Under a scalar gauge transformation,

\begin{align}
t & \rightarrow \tilde{t} = t + \xi^1 Y, \\
y & \rightarrow \tilde{y} = y + \xi^0 Y, \\
x^i & \rightarrow \tilde{x}^i = x^i + \xi^S Y^i,
\end{align}

the metric variables transform as

\begin{align}
N & \rightarrow \tilde{N} = N - \xi^0 Y - \xi^1 Y^i - \sqrt{2b} \delta\varphi \xi^\alpha, \\
A & \rightarrow \tilde{A} = A + \xi^1 - e^{2\sqrt{2b} \varphi} \xi^\alpha, \\
C & \rightarrow \tilde{C} = C + e^{-2\alpha + 2\sqrt{2b} \varphi} k \xi^\alpha - \xi^S, \\
\Phi & \rightarrow \tilde{\Phi} = \Phi - W \xi^\alpha - \xi^1, \\
B & \rightarrow \tilde{B} = B - e^{-2\alpha} k \xi^\alpha - \xi^S, \\
E & \rightarrow \tilde{E} = E + k \xi^S.
\end{align}

Since there are only two constraint equations, two of the four variables can not be determined. On the other hand, there are two physical degrees of freedom in the bulk for scalar type perturbations. One of them corresponds to the scalar field and the other to the graviscalar.
\[ \Psi \rightarrow \bar{\Psi} = \Psi - \frac{1}{3} k \xi^S - W' \xi^y - \delta \xi^t, \]
\[ \delta \phi \rightarrow \delta \bar{\phi} = \delta \phi - \dot{\phi} \xi^t - \xi' \xi^y, \]  
where prime denotes the derivative with respect to \( y \).

In our background spacetime, the gauge fixing condition imposed in \( 37 \) corresponds to

\[ N = \sqrt{2} b k \delta \phi, \quad A = C = 0. \]  

These conditions do not fix the gauge completely. We use this remaining degree of freedom to keep the brane location unperturbed at \( y = y_0 \). Then, the boundary conditions on the brane for all the remaining variables become Neumann boundary condition;

\[ \partial_y N|_{y_0} = \partial_y \Phi|_{y_0} = \partial_y E|_{y_0} = \partial_y B|_{y_0} = 0. \]  

All variables can be expanded by the same mode functions in the \( y \)-direction as

\[ \Phi = \Phi_0(t) \psi_0(y) + \sum \Phi_m(t) \psi_m(y), \ldots, \]  
where \( \psi_0 \) is constant, and

\[ \psi_m(y) = c (\sinh H y)^{1/2 + \mu} B^{-1/2 - \mu}_{-1/2 + i \nu} (\cosh H y), \]
\[ B^\alpha_\nu (\cosh H y) = Q^{1/2 - \mu}_{1/2 + i \nu} (\cosh H y_0) P^\alpha_{-\mu} (\cosh H y), \]
\[ -P^{-1/2 - \mu}_{-1/2 + i \nu} (\cosh H y_0) Q^\alpha_{-\mu} (\cosh H y), \]
\[ \mu = -\frac{1}{\Delta + 2}, \]
\[ \nu(m) = \sqrt{\frac{m^2}{H^2} - \mu^2}, \]  

where \( c \) is a normalization constant. The first and second terms in Eq. 36 represent the zero and KK modes, respectively. \( m^2 \) represents the squared KK mass for observers on the four-dimensional brane. There is a mass gap \( \delta m = \mu H \) between the zero mode and the KK continuum. The modes with \( 0 < m < \mu H \) are not normalizable. \( P^\alpha_{-\mu} \) and \( Q^\alpha_{-\mu} \) are associated Legendre functions.

We now turn to the mode functions in the \( t \)-direction. For the zero mode, we have another gauge degrees of freedom. As is evident from Eq. 38, gauge transformation satisfying \( \xi^y = 0 \) and \( \xi'^t = \xi^S t = 0 \) do not disturb the conditions Eq. 44. We can use this degree of freedom to set \( B = E = 0 \), because the solutions do not depend on \( y \) for the zero mode. The solutions are given by

\[ N_0 = \sqrt{2} b k \delta \phi_0 \]
\[ = c_0 \frac{1}{3} \Delta + 2 \left( \rho_\mu - 3 \Delta + 8 \right) \right), \]
\[ \Psi_0 = -c_0 \frac{2}{3} \Delta + 3 \left( \rho_\mu + \frac{1}{\Delta + 4} \right) \right), \]
\[ \phi_0 = -\Psi_0 - N_0, \]  

where \( c_0 \) is a constant and \( \rho_\alpha \) is defined as

\[ \rho_\alpha (\eta) = (\pm \eta) H_\alpha (\pm \eta), \]  

where \( H_\alpha \) is an arbitrary linear combination of Hankel functions \( H^{(1)}_\alpha \) and \( H^{(2)}_\alpha \). We note that the number of physical degree of freedom is one for the zero mode. This solution is already obtained by Koyama and Takahashi \( 29, 30 \).

The solutions for the KK modes in the gauge condition Eq. 44 are obtained as

\[ N_m = \sqrt{2} b k \delta \phi_m \]
\[ = -3 \Delta + 8 \left[ \frac{c_1 (2 \mu - 1) \eta \rho_{\mu - 1}}{\Delta + 4} \right] + (iv + \mu) (iv + \mu - 1) \rho_{\mu - 1} + 2 c_2 \rho_{\mu - 1}, \]
\[ \Phi_m = c_1 (\pm \eta) \rho_{\mu - 1} + N_m, \]
\[ \Psi_m = -3 \Delta + 8 \left[ \frac{c_1 (2 \mu - 1) \eta \rho_{\mu - 1}}{\Delta + 4} \right] + (iv + \mu) (iv + \mu - 1) \rho_{\mu - 1} + 2 c_2 \rho_{\mu - 1}, \]
\[ E_m = c_1 (\pm \eta) \rho_{\mu - 1} - \frac{2}{\Delta + 4} c_1 (2 \mu - 1) \eta \rho_{\mu - 1} + (iv + \mu) (iv + \mu - 1) \rho_{\mu - 1} + 3 \Delta + 8 \left[ \frac{c_1 (2 \mu - 1) \eta \rho_{\mu - 1}}{\Delta + 4} \right] \rho_{\mu - 1}, \]
\[ B_m = 2 c_1 e^{\alpha \eta} \rho_{\mu - 1} (iv + \mu) \rho_{\mu - 1} + 3 \Delta + 8 \left[ \frac{c_1 (2 \mu - 1) \eta \rho_{\mu - 1}}{\Delta + 4} \right] \rho_{\mu - 1}. \]  

We should note that the solution obtained in \( 30 \) is a particular solution where \( c_1 \) and \( c_2 \) are related (see Appendix C).

2. Solutions for \( F_{\mu \nu} \) and \( F_\phi \)

Next, we calculate the solutions for \( \delta F_{\mu \nu} \) and \( \delta F_\phi \), using the solutions of the bulk gravitational field summarized above. The above two solutions are obtained in the Gaussian-normal gauge condition with respect to the brane. After a gauge transformation to the longitudinal gauge (see Appendix C), we substitute the solutions projected on the brane into the four-dimensional perturbed Einstein equations in Appendix A, Eq. 50, 58, 59, and 61. Then we obtain \( \delta F_{\mu \nu} \) and \( \delta F_\phi \) as

\[ \delta F_{\mu \nu} = -c_1 e^{-2 \alpha \rho_{\mu - 1}} \rho_{\mu - 1} \psi_m (y_0), \]
\[ \delta F_\phi = -c_1 e^{-2 \alpha \rho_{\mu - 1}} (iv + \mu) \rho_{\mu - 1} \psi_m (y_0) + \rho_{\mu - 1} \right), \]
\[ \delta F_\phi = c_1 (iv + \mu - 1) e^{-2 \alpha} \left[ \frac{1}{iv - 1} \rho_{\mu - 1} \right] \psi_m (y_0) \]
\[ + k \rho_{\mu - 1} \eta \right), \]
\[ \delta F_\phi = c_1 (iv + \mu - 1) e^{-2 \alpha} \left[ \frac{1}{iv - 1} \rho_{\mu - 1} \right] \psi_m (y_0) \]
\[ \delta F_\phi = c_1 (iv + \mu - 1) e^{-2 \alpha} \left[ \frac{1}{iv - 1} \rho_{\mu - 1} \right] \psi_m (y_0) \]
\[
- \frac{\mu}{(\nu + \mu - 1)(\nu - 1)}\left(\rho_{\nu+1}(\eta) + \rho_{\nu-2}(\eta)\right)\psi_m(y_0) \\
+ \hat{c}_2 \frac{4\sqrt{2}b\kappa^{-1}}{\Delta + 4} e^{-2\alpha(k\eta)} \rho_{\mu}(\eta)\psi_m(y_0),
\]
where
\[
\hat{c}_1 = (\nu + \mu)(\nu - \mu)k^2 c_1 = -\frac{m^2}{H^2}k^2 c_1,
\]
\[
\hat{c}_2 = (\nu + \mu)(\nu - \mu)k^2 c_2 = -\frac{m^2}{H^2}k^2 c_2.
\]
As is expected, \(\delta F_{\mu\nu}\) and \(\delta F_\varphi\) vanish for \(m^2 = 0\).

3. Dark radiation and bulk perturbation

In Sec IV B 2 we calculated the contributions of the bulk perturbation to \(F_{\mu\nu}\) and \(F_\varphi\) on the brane. Here, we discuss their relation to the dark radiation. As mentioned before, there are two physical degrees of freedom in the bulk for scalar perturbations. One of them corresponds to the scalar field and the other to the graviscalar. Since the \(c_2\) component of \(\delta \rho F\) vanishes, it is expected that the solution of \(c_1\) includes the dark radiation at large scales and thus corresponds to the graviscalar. This can be explicitly shown if we take \(\nu + \mu - 1 = 0\) and a linear combination of Hankel functions:

\[
H^{(1)}_\alpha(-k\eta) + e^{-2\alpha} H^{(2)}_\alpha(-k\eta) = 2e^{-i\alpha\pi} J_{-\alpha},
\]
such that \(H^{(1)}_\alpha(-k\eta) \propto (-k\eta)^{-\alpha}\) for \(-k\eta \to 0\). In this case, the above solutions for \(\delta F_{\mu\nu}\) and \(\delta F_\varphi\) becomes

\[
\delta \rho F = -(1 - 2\mu)c_1 e^{-2\alpha} \rho_{1-\mu}\psi_m(y_0) \\
\propto -\hat{c}_1 e^{-4\alpha - \sqrt{2}b\kappa \varphi},
\]
\[
\delta q F \propto -\hat{c}_1 \frac{-k\eta}{2\mu} e^{-4\alpha - \sqrt{2}b\kappa \varphi},
\]
\[
\delta \pi F \propto -\hat{c}_1 \frac{-k\eta}{4(\mu + 1)} e^{-4\alpha - \sqrt{2}b\kappa \varphi} \\
+ \hat{c}_2 \frac{3\Delta + 8}{\Delta + 4} n^{-2} e^{-4\alpha - \sqrt{2}b\kappa \varphi},
\]
\[
\delta F_\varphi \propto \hat{c}_1 \sqrt{2b\kappa^{-1}} e^{-4\alpha - \sqrt{2}b\kappa \varphi} \\
+ \hat{c}_2 \frac{4\sqrt{2b\kappa^{-1}}}{\Delta + 4} n^{-2} e^{-4\alpha - \sqrt{2}b\kappa \varphi},
\]
for \(-k\eta \to 0\). The time dependence of \(\delta \rho F\) coincides with that of the solution of the constraint equation Eq. (56) for large scales. It should be noted that the condition \(\nu + \mu - 1 = 0\) can be written as

\[
m^2 = (2\mu - 1)H^2(< \mu^2 H^2).
\]

This is quite an interesting result. The dark radiation corresponds to a non-normalizable KK mode. For RS model \(b = 0\), the mass squared become \(2H^2\).

It should be also emphasized that the behavior of \(\delta \pi F\) which corresponds to the dark radiation is obtained here (Eq. (58)). This variable can not be known by the constraint equation Eq. (54) because \(\delta \pi F\) is dropped for \(k \to 0\). As mentioned above, this uncertainty prevents us from predicting CMB anisotropies in brane world models [27, 28]. This issue is discussed in the section VII.

V. BLACK HOLE IN THE BULK AND A KK MODE

In the previous section, we showed that the dark radiation corresponds to a non-normalizable KK mode of cosmological perturbations. Here, we discuss the connection between this KK mode and the black hole in the bulk when the black hole mass is perturbatively small.

There is a black hole solution with a bulk scalar field with an exponential potential, which coincides with the background spacetime of the Koyama-Takahashi model when the black hole mass vanishes. We first review this black hole solution in the section V A. We also calculate the behavior of \(E_{\mu\nu}\) in the case where the black hole mass is perturbatively small. On the other hand, we calculate the perturbation of \(E_{\mu\nu}\) using the solutions of the perturbed five-dimensional Einstein equations for \(\nu + \mu - 1 = 0\). It is shown that the asymptotic behavior of \(E_{\mu\nu}\) in the bulk coincides with the one which originate from the black hole in the bulk.

A. Black hole solution with a bulk scalar field

Here we review a black hole solution with a bulk scalar field which has the exponential potential in the bulk Eq. (42). When the black hole mass vanishes, this solution coincides with the background spacetime of Koyama-Takahashi model.

We can find a static solution for the bulk with vanishing cosmological constant as

\[
ds^2 = -h(R)dt^2 + \frac{R^{3\Delta + 8}}{h(R)}dR^2 + R^2 \delta_{ij}dx^idx^j,\]
\[
\varphi = 3\sqrt{2}b\kappa^{-1}\ln(R).
\]

where

\[
h(R) = \lambda_0^2 R^2 - CR^{6b^2 - 2},
\]

\(C\) is an arbitrary constant and related to black hole mass. Here we defined

\[
\lambda_0^2 = \frac{\lambda_0^2}{18} \left(1 + \delta \frac{8}{\Delta}\right).
\]

For \(b = 0\), this solution becomes AdS-Schwartzshild. The Friedmann equation on the brane with the tension Eq. (3) is obtained as [13]

\[
\left(\frac{\dot{R}}{R}\right)^2 = \frac{4}{9} \left(\frac{\delta}{\Delta}\right) \lambda_0^2 R^{-(3\Delta + 8)} + CR^{-(3\Delta + 16)/2},\]

\[
(\dot{R}/R)^2 = \frac{4}{9} \left(\frac{\delta}{\Delta}\right) \lambda_0^2 R^{-(3\Delta + 8)} + CR^{-(3\Delta + 16)/2},\]

[13]
where dot is the derivative with respect to cosmic time on the brane.

For $C = 0$, the background spacetime Eq. (14) can be obtained from this metric by a coordinate transformation,

\[
R = \left( -\frac{3}{2} \frac{\lambda_0 (\Delta + 2) z}{2^{3/2}} \right)^{2/3(\Delta + 2)},
\]

\[
T = \frac{\tau}{\lambda_0}.
\]

When there is a perturbatively small mass of black hole in the bulk, the metric Eq. (14) is modified as

\[
ds^2 = e^{2P(z)}((1 + \delta C f(z))dz^2 - (1 - \delta C f(z))d\tau^2 + \delta_{ij}dx^i dx^j),
\]

where

\[
f(z) = \frac{1}{\lambda_0} R(z)^{62-4},
\]

and $\delta C$ is perturbed black hole mass. It is noted that this modification can not be regarded as a perturbation at $z \to \infty$ or $R \to 0$. We focus our attention to the region sufficiently far from the black hole so that the above modification can be treated as perturbation. We can easily calculate five-dimensional Weyl tensor in this coordinate system as

\[
C_{\tau \tau \tau \tau} = -\frac{1}{4} \delta CR(z)^2 \partial^2 f(z).
\]

By a coordinate transformation Eq. (16), this is related to Weyl tensor in our background spacetime Eq. (5) as

\[
C_{\eta \eta \eta \eta} = \eta^2 H^2 C_{\tau \tau \tau \tau}.
\]

Finally, we obtain the behavior of $E_{tt}$:

\[
\delta E_{tt} = \frac{9}{8} \Delta \delta C e^{-4a - \sqrt{2} b \kappa \varphi} \left( \frac{\sinh H y}{\sinh H y} \right)^{2\mu - 1}.
\]

Another components can be obtained by the homogeneity and isotropy of three-dimensional spatial coordinates and the condition $E^\mu_\mu = 0$.

**B. Perturbations of $E_{\mu \nu}$ in the bulk**

Here we calculate perturbations of $E_{\mu \nu}$ in the bulk, using the solutions of the five-dimensional perturbed Einstein equations for $i\nu + \mu - 1 = 0$ at large scales. In Appendix D, we present the perturbation formula for five-dimensional Weyl tensor in the Gaussian normal gauge. Substituting the solutions of the bulk gravitational field, we get

\[
\delta E_{tt} = -\Delta \frac{c_1 k^2 e^{-2\alpha_1 - \mu - 1}}{12} \left( \frac{1}{H^2} \mu^2 \psi_m(y) - \psi_m(y) \right).
\]

Here we took $i\nu + \mu - 1 = 0$ and $-k \eta \to 0$. Using the solution for $\psi_m(y)$, the $y$-dependence of $E_{tt}$ can be evaluated as

\[
\frac{1}{H^2} \mu^2 \psi_m(y) - \psi_m(y) = -\frac{2\mu}{1 - 2\mu} \left( \sinh H y \right)^{1/2 + \mu} B_{1/2 - \mu}^{3/2 - \mu} (\cosh H y).
\]

On the brane, thanks to the junction condition, we can show that

\[
B_{1/2 - \mu}^{3/2 - \mu} (\cosh H y_0) = (1 - 2\mu) B_{1/2 - \mu}^{1/2 - \mu} (\cosh H y_0).
\]

Then $E_{tt}$ on the brane is given by

\[
\delta E_{tt}(y_0) = \frac{\Delta}{2} k^2 e^{-2\alpha_1 - \mu} \rho_1 - \psi_m(y_0) - 1 \delta C.
\]

Comparing this solution with Eq. (70), it is possible to express $c_1$ by the black hole mass $\delta C$ as

\[
c_1 k^2 = \frac{9}{4} \frac{(-H y)^{2\mu - 1}}{\mu_1 - \mu} \psi_m(y_0)^{-1} \delta C.
\]

We note that the left hand side does not depend on time for $-k \eta \to 0$. We can also rewrite the induced four-dimensional Einstein equation Eq. (16) in accordance with the Friedmann equation Eq. (63) as

\[
(1) G_{\mu \nu} = \frac{8}{3 \Delta} (1) \delta H_{\mu \nu} - \tilde{E}_{\mu \nu},
\]

where

\[
-\tilde{E}_{\mu \nu} = -E_{\mu \nu} + \frac{2}{3} \kappa^2 T_{\mu \nu}^{(5)} - \frac{2b^2}{\Delta} \lambda_3 \delta e^{-2\sqrt{2}\kappa \varphi} q_{\mu \nu}.
\]

If we substitute the solutions for $i\nu + \mu - 1 = 0$ and then use the relation Eq. (78), $\tilde{E}_{tt}$ becomes

\[
-\delta \tilde{E}_{tt} = 3 \delta C e^{-4a - \sqrt{2} b \kappa \varphi}.
\]

Clearly, this corresponds to the dark radiation term in Eq. (63). Finally we investigate the $y$-dependence of the $E_{tt}$. For large $H y$, the $y$-dependence of $E_{tt}$ behaves as

\[
\frac{1}{H^2} \frac{9}{4} (\mu_1 - \mu) \psi_m(y) - \psi_m(y) \propto (\sinh H y)^{2\mu - 1}.
\]

This behavior is precisely the same as $\delta E_{tt}$ derived from the BH solution. Thus the correspondence is held also in the bulk.

In the perturbation solutions, there is also anisotropic part of $E_{\mu \nu}$. The result for $i\nu + \mu - 1 = 0$ is

\[
\delta \pi_E = -\frac{8}{3 \Delta} \frac{(-k \eta)^2}{4 \mu (\mu + 1)} \delta E_{tt},
\]

where $\delta \pi_E$ is defined in the same way with $\delta \pi_F$. 
VI. SUMMARY AND DISCUSSION

In this paper, we discussed the connection between the dark radiation and the bulk perturbation in a dilatonic brane world based on a model proposed by Koyama and Takahashi. We first derived the four-dimensional effective Einstein equations on the brane developed in Ref. We separated the contributions of the bulk scalar field from $E_{\mu \nu}$. Then the four-dimensional effective theory becomes the BD theory with the corrections given by $E_{\mu \nu}$ and $F_{\mu \nu}$. We then considered the dark radiation in cosmological perturbation on the brane. The perturbed Einstein equations include the four variables $\delta \rho$, $\delta q$, $\delta \pi$ and $\delta F_{\mu \nu}$ which carry the information in the bulk. There are two constraint equations obtained from the four-dimensional Bianchi identity. We showed that the dark radiation appears as a solution for the constraint equations at large scales.

We can derive a complete set of the solutions for $\delta \rho$, $\delta q$, $\delta \pi$ and $\delta F_{\mu \nu}$ only when we solve the bulk gravitational fields, which have two physical degrees of freedom, the scalar field perturbation and the graviscalar. We calculated $\delta \rho_{\mu \nu}$, $\delta q$, $\delta \pi$ and $\delta F_{\mu \nu}$ on the brane using these two independent solutions of the bulk perturbations obtained in Refs. We found that if we take a non-normalizable KK mode with mass $m^2 = (2\mu - 1)H^2$, the contribution from the graviscalar in the bulk corresponds to the dark radiation at large scales. We also checked that this solution corresponds to the excitation of a small black hole in the bulk by calculating $\delta E_{\mu \nu}$.

This relation is exactly the same as Eq. for $b = 0(\mu = 3/2)$. It is somewhat a surprising result. Despite the fact that the low energy expansion scheme is applicable only for two branes model, our result shows that it can be used to investigate the bulk gravitational field in one brane model if we choose the boundary condition at the second brane properly. We plan a more detailed study on the effectiveness of the low energy expansion scheme using our exactly solvable model.

In this paper, we did not consider the normalization of the perturbations. This can be fixed if we perform the quantization of the perturbations. This was partially done in for the scalar field perturbation. However, precisely speaking, we need to quantize two degrees of freedom independently. This issue is also left for a future study.

APPENDIX A: PERTURBED EINSTEIN EQUATIONS ON THE BRANE

In this appendix, we present the perturbed effective four-dimensional Einstein equations. The linear scalar metric and scalar field in the longitudinal gauge is taken as

$$ds^2 = -(1 + 2\Phi(t)Y)dt^2 + e^{2\alpha}(1 + 2\Psi(t)Y)dx^idx^j, \quad \varphi = \varphi + \delta \varphi Y.$$
The perturbed four-dimensional Einstein equations are given by (t,t):

\[ 6\alpha^2 \left( \frac{\Phi - \dot{\Psi}}{\alpha} \right) - 2k^2 e^{-2\alpha} \Psi = - \delta \rho_F - 3\sqrt{2}b k \alpha \dot{\varphi} \left( \frac{\Phi - \dot{\Psi}}{\alpha} \right) + \sqrt{2}b k \alpha^2 e^{-2\alpha} \delta \varphi \]

\[ - 2\sqrt{2}b k \Delta \frac{\Delta + 4}{2} \alpha^2 \delta e^{-2\sqrt{2}b k \alpha} \delta \varphi \quad (86) \]

(i,i):

\[ \dot{\Psi} + 3\dot{\Psi} - 2\Phi \dot{\varphi} - 3\dot{\Phi} - \dot{\varphi} + \frac{1}{3} k^2 e^{-2\alpha} (\Psi + \Phi) = - \sqrt{2}b k \left( \frac{\Phi - 2\dot{\varphi} \dot{\varphi} - \dot{\varphi} - \frac{1}{2} \dot{\varphi} + \frac{1}{2} \delta \varphi \right) \]

\[ + \alpha \delta \varphi + \frac{1}{3} k^2 e^{-2\alpha} \delta \varphi \right) + \frac{\Delta + 11/3}{2} k^2 (\dot{\varphi}^2 \Phi - \dot{\varphi} \delta \varphi) \]

\[ + \sqrt{2}b k \Delta \frac{\Delta + 4}{2} \lambda_0 \delta e^{-2\sqrt{2}b k \alpha} \delta \varphi \]

\[ - \frac{1}{6} (\delta \rho_F + 3\sqrt{2}b k \delta F \dot{\varphi}) \quad (87) \]

(i,j):

\[ - k^2 e^{-2\alpha} (\Phi + \Psi + \sqrt{2}b k \delta \varphi) = \delta \pi_F, \quad (88) \]

(t,i):

\[ - 2k e^{-\alpha} (\Phi - \dot{\varphi}) = \frac{2k^2}{3} k e^{-\alpha} \dot{\varphi} \delta \varphi \]

\[ + \sqrt{2}b k e^{-\alpha} (\dot{\varphi} + \sqrt{2}b k \dot{\varphi} \delta \varphi - \dot{\varphi} \Phi) - \delta \pi_F. \quad (89) \]

Introducing a canonical variable for scalar perturbations

\[ Q = \delta \varphi - \frac{\dot{\varphi}}{\alpha} \Psi = \delta \varphi - \frac{3\sqrt{2}b k}{\kappa} \Psi, \quad (90) \]

the perturbed scalar field equation can be rewritten as

\[ \ddot{Q} + (3\dot{\alpha} + \sqrt{2}b k \dot{\varphi}) \dot{Q} + k^2 e^{-2\alpha} Q = - \sqrt{2}b k \alpha^{-1} (\delta \rho_F + \delta \pi_F) - \delta F \dot{\varphi}. \quad (91) \]

Here we used the scalar field equation and the four-dimensional Einstein equations. It should be noted that Q is related to the curvature perturbation as

\[ R_c = \frac{\dot{\varphi}}{\varphi} Q, \quad (92) \]

which affect the amplitude of the CMB anisotropy.

The above Einstein equations and the equation for Q are not closed but include the terms due to the KK modes. As shown in the section IV.A the constraint equations for \( \delta F_{\mu \nu} \) and \( \delta F_\varphi \) Eq. (26) are not sufficient to determine these variables. We must solve the bulk dynamics to completely understand cosmological perturbations on the brane.

**Appendix C: SOLUTIONS IN THE LONGITUDINAL GAUGE**

In this appendix, we present the solutions of five-dimensional Einstein equations for scalar perturbation in the longitudinal gauge. By a gauge transformation of the solutions given in Sec. [IV.B.1] to the longitudinal gauge, we get

\[ \Psi_L = - \frac{2}{3(\Delta + 2)} i \nu + \frac{\mu - 1}{i \nu - 1} c_1 \]

\[ \times \left[ \left( \frac{\Delta + 2}{\Delta + 4} \right) (i \nu + \mu)(i \nu - \mu) \phi(\eta) \psi_m - \phi(\eta) \cosh H_y \psi_m \right. \]

\[ + \frac{2}{\Delta + 4} (i \nu - 1)(i \nu + \mu) \rho \right. \]

\[ \times \left. \left( \frac{\Delta + 8}{3(\Delta + 4)} \right) c_2 \left[ (i \nu + \mu - 1)(i \nu - 1) \phi(\eta) \psi_m \right. \]

\[ + \frac{2}{\Delta + 2(-k \eta)^2} \zeta_m \right) \right] \right], \quad (93) \]

\[ \Phi_L = \frac{2}{3(\Delta + 4)} (i \nu + \mu)(i \nu - 1)c_1 \]

\[ \times \left[ \left( \frac{1}{(i \nu + \mu)(i \nu - 1)} \phi(\eta) \left( (i \nu + \mu)(i \nu - \mu) \psi_m \right. \right. \]

\[ - \frac{2}{\Delta + 2(-k \eta)^2} \sinh H_y H \right] \]

\[ \frac{\Delta + 4 \cosh H_y \psi_m}{\Delta + 2 \sinh H_y H} \right] \right] \]

\[ + \frac{2}{\Delta + 2(-k \eta)^2} \psi_m \]

\[ + (i \nu - \mu)(3i \nu + 3 - \mu) \rho \]

\[ \left( \frac{(-k \eta)^2}{2} \right) \psi_m \]

\[ - \frac{3 \Delta + 8}{3(\Delta + 4)} c_2 \left[ - \rho \right] \]

\[ \mu \right) \left( i \nu + \mu - 1 \right) \rho \right) \psi_m \]

\[ \left. \frac{2}{\Delta + 2(-k \eta)^2} \sinh H_y H \right] \right], \quad (94) \]

\[ N_L = - \Psi_L - \Phi_L, \quad (95) \]

\[ A_L = 2k^{-1} e^{-\alpha} \psi_m \left[ \right] \]

\[ \left. c_1 \kappa \mu \frac{i \nu + \mu - 1}{i \nu - 1} \rho \right) \psi_m \]

\[ - \frac{3 \Delta + 8}{\Delta + 4} \left( c_2 - \frac{2c_1}{3\Delta + 8} \right) (i \nu + \mu) \left( i \nu + \mu - 1 \right) \left. \right] \right], \quad (96) \]

\[ \delta \varphi_L = 3\sqrt{2}b k^{-1} (-c_2 \rho \psi_m + \Phi_L), \quad (97) \]

where

\[ \phi(\eta) = \rho \psi_m + \frac{\mu}{i \nu + \mu - 1} \rho \psi_m \]

\[ \zeta_m (y) = (i \nu - \mu) \psi_m \left( \frac{\cosh H_y \psi_m}{\sinh H_y H} \right). \]

If we take

\[ c_1 = \frac{c_2(3\Delta + 8)}{2(i \nu + \mu)(i \nu + \mu - 1)} \]
this solution becomes the one already obtained in Koyama and Takahashi [29, 30].

Appendix D: PERTURBATION FORMULAS FOR 5D WEYL TENSOR

In this appendix, we give the Wey tensor in our background spacetime. Here we take the Gaussian normal
gauge condition Eq.(43). The explicit expressions are as follows:

\[
C = \frac{e^{2W}}{2} \left[ \Phi'' - \Psi'' \right] + \frac{e^{2W + 2\sqrt{2}b\kappa \varphi}}{2} \left[ -\dot{N} + \ddot{\Psi} - \frac{k}{3} \ddot{B} + \sqrt{2b\kappa} \left( \Phi + \ddot{\Psi} - \frac{k}{3} B - 2\dot{N} \right) + \dot{\alpha} \left( \dot{N} - \Phi \right) - 2N \left( \sqrt{2b\kappa} \varphi + 2b^2 \kappa^2 \varphi^2 - \ddot{\alpha} - \sqrt{2b\kappa} \varphi \dot{\alpha} \right) + \frac{k^2}{6} e^{2W + 2\sqrt{2}b\kappa \varphi - 2\alpha} \left[ N + \varphi - 2\Psi - \frac{2}{3} E \right] \right], \quad (101)
\]

where we expanded $\delta^{(5)} C_{\mu\nu\rho\tau}$ in terms of the scalar harmonics as

\[
\delta^{(5)} C_{t\mu\nu} = CY, \quad \delta^{(5)} C_{\mu\nu\rho\tau\sigma} = e^{2\alpha} \left( \frac{1}{3} CY \delta_{ij} + C_2 Y_{ij} \right). \quad (103)
\]
